FIFESHIRE is situated between 56. 3. and 56. 25. N. Lat., and 2. 30. and 3. 50. W. Long., and bounded by the river and Firth of Tay on the north, by the German Ocean on the east, by the Firth of Forth on the south, and by parts of Kinross, Perth, and Clackmannan on the west. Its greatest length from west to east is about 41 miles, and its greatest breadth from north to south about 20 miles; its medium length from east to west is about 35 miles, and its medium breadth from north to south is nearly 13 miles. Its area is 459 square miles, or 293,760 imperial acres. Among the agricultural statistics collected by the Highland Society, and forwarded to the Board of Trade, the number of imperial acres in Fife to which the report is applicable amounts to 279,941. The most prominent features in Fifeshire, when viewed at a distance from the south, are the two Lomond hills in the middle of the county, the Bishop hills farther west, Largo Law farther east, and Normans Law and the Mount hill in the north-west and north of the county. The elevations of these hills have been ascertained by the ordnance surveyors to be above the level of the sea in feet as follows:—West Lomond, 1712·7; East Lomond, 1470·8; the highest Bishop hill, 1490·5; Largo Law, 953·0; Normans Law, 936·0; and the Mount hill, 730·3. Besides these there are numerous other elevations scattered over the county; and indeed it is everywhere found to present a pleasant variety of hill and valley, stretching in general from west to east, parallel to the Tay and the Forth. The principal valley is that through which the Eden flows, and is called the Howe of Fife, or Strath Eden. It lies to the north of the Lomond hills, which, with their western prolongation to the Cleish and Saline hills and their eastern continuation towards St Andrews, divide the county into the northern and southern portions. The valleys of the Leven and Ore are bounded by very gentle elevations, which in many places merge into the plain which may be said to slope from the central range to the Firth of Forth. The hills to the north of the Howe of Fife are a continuation of the Ochils, and are composed of an uninterrupted mass of trap rocks, flanked on either side by the lower beds of the old red sandstone

[1] Of his departure for Lisbon he has himself left the following melancholy record, in which his situation is painted a thousand times better than could have been done by any pen but his own: "On this day, Wednesday, June 26, 1754, the most melancholy sun I had ever beheld arose, and found me awake at my house at Fordhook. By the light of this sun, I was, in my own opinion, last to behold and take leave of some creatures on whom I doated with a mother-like fondness, guided by nature and passion, and uncured and unhardened by all the doctrine of that philosophical school, where I had learned to bear pains, and to despise death. In this situation, as I could not conquer nature, I submitted entirely to her, and she made as great a fool of me as she had ever done of any woman whatsoever; under pretence of giving me leave to enjoy, she drew me in to suffer, the company of my little ones during eight hours; and I doubt not whether in that time I did not undergo more than in all my distemper. At twelve precisely my coach was at the door, which was no sooner told me, than I kissed my children, and went into it with some little resolution. My wife, who behaved more like a heroine and philosopher, though at the same time the tenderest mother in the world, and my eldest daughter, followed me. Some friends went with us, others here took their leave; and I heard my behaviour applauded, with many murmurs and praises to which I well knew I had no title." (*Voyage to Lisbon*, p. 1.) This affecting passage remains a singular example of Fielding's natural strength of mind; and, indeed, the whole of the *Journey to Lisbon* shows that, whilst struggling at once with the depression and the irritability of disease, he could still exhibit a few flashes of that bright wit which used to set the world in a roar. "His perception of character, and power of describing it," says Sir Walter Scott, "had not forsaken him in those sad moments; for the master of the ship in which he sailed, the scolding landlady of the Isle of Wight, the military coxcomb who visits their vessel, are all portraits marked with the master-hand which traced Parson Adams and Squire Western."

formation. The Howe of Fife is entirely occupied by those upper strata of the old red sandstone to which Dr Anderson of Newburgh has given the name of the yellow sandstone. Mr Maclaren, in his work on the Geology of Fife and the Lothians, has named the same deposits the calciferous sandstone. The rocks of the southern division of Fifeshire chiefly belong to the coal formation of geologists, and form a portion of the great coal-field of the Forth. Here glance coal, or blind coal as it is sometimes called, is met with occasionally; slate coal, pitch coal, and cannel coal are occasionally found together in the same bed, and sometimes in separate strata in the same pit. From a charter dated in March 1291, it would appear that coal has been worked in this county for more than five centuries. In this charter William de Oberville grants liberty to the convent of Dunfermline to open a coal-pit in his lands of Pittencreiff. The principal coal-works at present are those in the parishes of Dunfermline, Beath, Dalgetty, Auchterderran, Ballingry, Dysart, Wemyss, and Markinch. In the southern division of the county three different limestone beds are met with, viz., the mountain or encrinitic limestone, the fresh-water limestone, and a stratum occurring in the midst of the coal measures which has received from geologists the name of the middle limestone. The first of these, the mountain limestone, is found in all directions around the outcrop of the coal strata. It is worked extensively at Charleston in the west of Fife, and at Fordel and Cults in the interior of the county. The fresh-water limestone is less extensively distributed, and is chiefly worked at Newbigging, near Burntisland, and used by the Carron Company in smelting iron.

Blackband ironstone also abounds in the Fife coal-fields, and for the last ten years it has formed one of the chief products of the county. It is raised by the Forth Iron Company at Oakly in the parish of Carnock, Steelend in Saline parish, and Cowden-Beath in the parish of Beath. There are also extensive mines at Lochgelly, Lumphinnans, Outh, Inzievar, and Killernie in the west of Fife, and at Winthank, near St Andrews, in the east of Fife. There are at present (1855) in full operation six smelting furnaces at Oakly, two at Lochgelly, and one at Lumphinnans. At Oakly alone there are more than 2000 workmen employed. The manufacture of malleable iron is now carried on to a considerable extent at the works of the Weardale Iron Company at Transy, near Dunfermline.

Sandstone abounds, and is quarried, in many places of the county, both within and without the bounds of the coal formation. It is sometimes of a fine grain and durable quality, is much used in the county for building, and is often exported for the purpose.

The trap rocks of Fifeshire may be divided into three portions, viz., that extending through the north of Fife, and forming the Ochils; 2dly, that extending through the central part of the county in a long series of hills from Saline to the neighbourhood of St Andrews; and, 3dly, that forming the masses of igneous origin protruding through the coal measures along the shores of the Forth, and rising to considerable elevations in the hilly district near Inverkeithing, and near Burntisland and Kinghorn, forming the Dunearn hill, Orrok hill, Glassmont hill, and the Bin, &c. Clinkstone forms generally the highest summit of the Ochils, greenstone and amygdaloid cap the Lomonds and the other hills of the central range, while basaltic rocks are chiefly perceptible in the detached masses of the trap which lie along the shores of the Forth.

In various parts of the county there are quarries in the trap rocks, from which the whinstone is taken for road metal. At Queensferry it is conveyed by sea to Newcastle and London for paving streets, and to various places on the English coast for the construction of harbours.

Pyrope, resembling the precious garnet, is sometimes found embedded in the trap tuff. At Ely they are gathered on the sea-beach, or picked out of the rocks, and sold to jewellers under the name of Ely rubies. Copper and zinc are also said to have been met with in several places, and lead has been worked in the Lomond hills. Marl is also often found in the lakes, and dug out in dry seasons for agricultural purposes.

There are now no mineral springs of any note in the county. The old ones have disappeared. The chalybeate spring on the east of Dysart is now little frequented for medicinal purposes, and the petroleum or ink Craig of Carnock is seldom visited even by the curious.

The only streams of any note in the county are the Leven and the Eden. The former issues from Lochleven in Kinross-shire, flows eastward from an elevation of about 362 feet above the sea level through a beautiful strath by Leslie, Balgonie, and Balfour, and after a course of about twelve miles falls into the Forth at the town of Leven. The latter river, the Eden, flows from Strathmiglo hills through the Howe of Fife by Cupar to near St Andrews, where it falls into the German Ocean, about 18 miles from its source.

The lakes in the county are numerous, though none of them are very large, such as those at Lindores, Kilconquhar, Kinghorn, Lochgelly, Camilla, Lochfittie, and Lochglow. The county once contained many more, which have been drained at great expense. Of these the most considerable were the lakes of Rossie and Lochore. Their beds are now used in raising valuable crops.

From the extensive drainage of the lakes and marshes, and the general improvement of the fields by cultivation, the climate within the last forty years may now be described as good. The harvests are early, and the snow does not lie long on the ground. As the direction of the hills is from east to west, vegetation is often checked in the spring months by the east winds which then prevail.

The soil above the trap rocks is in general of good quality, and where the subsoil is coal or sandstone it is in general of inferior quality. There is still a considerable portion of moor and moss in the Howe of Fife; and near Dunferm line and Lochgelly;—and between St Andrews and Ferryport, and from Leven on the Forth for many miles eastward, as well as in other places, there are considerable tracts covered with drift sand.

The number of farms or holdings in Fife is about 1175: of these 534 contain less than 100 acres and 641 more than 100 acres. The most improved implements of husbandry are everywhere in use. Threshing-mills, moved by horses, by water power, or by steam engines, are to be found on all farms.

The principal manures in use are farmyard dung, seaweed cast ashore and cut from the rocks, bone-dust, and guano. Lime and marl are also in use in certain localities.

All the farm crops common in Scotland are cultivated here, and a great portion of them on a large scale. According to the Highland Society's report to the Board of Trade upon the crop of 1854, the number of acres in tillage was made up thus: wheat 24,252$\frac{1}{4}$, barley 27,937$\frac{3}{4}$, oats 43,591$\frac{1}{4}$, rye 417$\frac{1}{4}$, bere or bigg 16$\frac{1}{4}$, beans 3894, pease 718$\frac{1}{4}$, vetches 1397$\frac{1}{2}$, turnips 27,961$\frac{3}{4}$, potatoes 14,486$\frac{3}{4}$, mangold 78, carrots 43, cabbage 7$\frac{1}{2}$, flax 1648$\frac{3}{4}$, turnip seed 58$\frac{3}{4}$, bare fallow 3547$\frac{1}{4}$. The number of acres in grass was made up thus: grass in the rotation of the farm 62,749$\frac{3}{4}$, permanent pasture 29,931$\frac{3}{4}$, irrigated meadows 1043$\frac{3}{4}$, sheep walks 10,378$\frac{1}{4}$. The acres in buildings, woods, &c., were made up of houses, roads, fences, &c., 5903$\frac{1}{4}$, waste 4330$\frac{3}{4}$, and woods 15,548.

The farm stock in Fife, according to the same statistics, is stated to consist of—horses 10,953, milch cows 8586, other cattle 22,371, calves 83,111, ewes, gimmers, and ewe hogs, 32,550, tups, wethers and wether hogs 33,866, swine 11,485.

The gross produce of the county was—wheat 697,252 bushels, barley 1,075,603, oats 1,656,467, bere or bigg 540, beans 111,952, turnips 405,445, potatoes 68,087.

Fifeshire.

The average produce per imperial acre in Fife was—wheat 28 bushels and 3 pecks, barley 38 bushels and 2 pecks, oats 38 bushels, bere or bigg 33 bushels and 1 peck, beans 28 bushels and 3 pecks, turnips 14 tons 10 cwts., potatoes 4 tons 14 cwts.

It will be found, from a comparison of the statistics of the Scots counties, as given by the Highland Society, that Fifeshire grows the greatest quantity of wheat and flax. It also grows the largest proportion of barley, its quantity being about one-seventh of the whole of that crop raised in Scotland.

The cattle of the Fife breed are not now in so much repute as formerly. The horses are much the same as those in use in all the lowlands of Scotland. A great many pigs have of late years been reared. Pigeons are still numerous, and the pigeon-houses have been estimated at not less than 300.

There is nothing remarkable in the zoology of Fifeshire. Rabbits abound in certain localities, and hares, pheasants, and partridges are plentiful. There are a few grouse and black cock, and fallow deer are occasionally seen. The flora of the country is nearly the same as that of Mid-Lothian. Extensive plantations have, since the commencement of this century, been made in almost every parish.

Grain is sold extensively in stock and sample at various weekly markets in Fife, of which the most considerable are at Kirkcaldy, Dunfermline, Cupar, and St Andrews; and these and every other town of any consequence have one or two yearly fairs for the sale of horses and cattle and agricultural produce, and for hiring farm servants and the purchase of agricultural implements, &c.

There are three *retteries* in the county for the manufacture of flax from the straw grown in the county, and about 150 hands are employed in this branch of business.

In 1850 this county possessed forty flax-spinning mills, which turned 52,344 spindles, had a moving steam-power equal to that of 786 horses, and a water-power equal to that of 567 horses. These mills employed 1038 males and 2942 females. Mr Fergus's great flax-spinning mill at Prinlaws, near Leslie, is the largest of the kind in Scotland. The flax power-loom mills in 1850 were reported to be only three in in number, to employ 194 looms, to have a steam-power equal to that of 42 horses, and to employ 54 males and 166 females.

The number of hand-loom linen weavers employed at present is estimated at 13,000. About 5000 more hands, chiefly women and children, are engaged by the weavers in the preparation of the yarns for them, and about 400 hands more are employed in the bleaching of these yarns at about twenty separate bleachfields, some of which are on a large scale.

Although a portion of the yarn spun is bleached and made into cloth in the county, a great portion is also exported to the Continent unbleached.

The nature of the cloth manufactured ranges from the coarsest sacking, and light, plain, and fancy dowlas, with ticks and checks, to the finest damask, and is extensively exported to all parts of the world. The fine table linens, damasks, and diapers, used by her Majesty's household at Balmoral and Buckingham Palace, were made in this county, and the reputation of the Fife manufacture of these articles, particularly at Dunfermline, was fully sustained at the London Exhibition in 1851. The other seats of this trade are Newburgh, Kingskettle, Dysart, Kirkcaldy, and Cupar. A considerable part of the linens manufactured in Fife is sent, before being sold, to be bleached in Perthshire and Forfarshire, and even to Ireland. Besides the linen cloth manufacture, the wool-trade, to a small extent, also exists in Fife. The process of spinning and weaving is carried on in two mills, moved by water with a power equal to that of 28 horses, which turn 1480 spindles, and drive 26 looms. These mills employ 25 males and 34 females.

Since the report upon the state of the linen trade was framed, from which the information above given was taken relative to the number of power-looms employed in the manufacture of cloth, it has been greatly increased, and they have been lately estimated at the number of 700.

Fifeshire.

Besides the trades and manufactures of the county, ship-building is carried on at Dysart, where there is a wet dock and a Morton's slip for raising vessels out of the water for repair, and at Burntisland, where there is a good harbour and dry dock. It is also carried on at other ports in the county. There are also extensive distilleries and breweries of ale, and several paper mills, brick and tile works, potteries, iron founderies, and tanneries, &c.

The shipping of the county is extensive, and its vessels trade to all parts of the world. The state of the harbours and the extent of their trade will be seen in the articles FORTH and TAY.

The banking business of the county is extensive; and is conducted in every town of any consequence by upwards of 30 branches of the principal Scots banks.

Private railways of wood and iron have been used for many years in transporting for several miles the produce of coal and lime quarries to the harbours where they are shipped. The most extensive of these railroads is that belonging to the Earl of Elgin. It proceeds from near Dunfermline to Charleston harbour, and has been for many years open to the public for the purpose of carrying passengers.

The great public trunk iron railway, from Burntisland on the Forth to Ferry-Port-on-Craig on the Tay, was opened throughout in the year 1848. The length of it between these two points is 36 miles. It has a branch from Thornton to Dunfermline of $15\frac{1}{4}$ miles, and from the station at Dunfermline this branch is continued to Stirling by the Stirling and Dunfermline Railway Company. From Ladybank station, on the trunk line, a branch is also carried for 16 miles to its junction with the Scottish Central Railway near Perth. It thus affords direct railway communication between Edinburgh and Dundee, and also to Dunfermline. A single line railway from Thornton station to Leven, 6 miles long, was attached to it in 1854; and a single line railway, from Leuchars station to St Andrews, $5\frac{3}{4}$ miles long, was attached to it in 1852. Bills are at present (1855) before parliament for forming a railway 14 miles long from Ladybank station to Kinross by Auchtermuchty, and to form a railway from Leven to Kilconquhar, in continuation of that from Thornton station.

The Edinburgh and Northern Railway Company, which formed the first of these railways, is now united with the Granton Railway Company, and the united company has assumed the name of the Edinburgh, Perth, and Dundee Railway Company.

It has acquired stations in Edinburgh and Leith, and at Trinity and Granton, in Mid-Lothian, and formed or completed railways between all these stations. It has also acquired the ferries between Granton and Burntisland, and between Ferry-Port-on-Craig in Fife and Broughty in Forfarshire. It has also formed branch railways from the trunk line to Pettycur and Kirkcaldy harbours, and purchased the harbours of Kinghorn and Pettycur, Ferryport, and Broughty, and extensive properties at all the harbours and stations where necessary for the undertaking.

The capital expended on these works and purchases, and their appendages, including the plant of the railway, &c., and interest, amounted on 31st January 1855 to L.3,277,000, of which L.1,661,000 has been paid by the shareholders, and L.1,616,000 has been borrowed on debenture or from banks or otherwise. The revenue arising from the traffic amounted for the year ending at the same date to L.155,453, 11s. 3d., which was made up as follows:—For 1,216,168 passengers, L.65,885, 10s. 2d.; for 292,794 tons of goods,

231,866 tons of coals, 10,359 cattle, 29,981 sheep, 2353 pigs, L.87,280, 15s.; and for miscellaneous articles, L.2287; 6s. 1d. The working expenses for the same year amounted to about L.88,613, leaving a surplus for the payment of interest, and towards the liquidation of the debts of the company, of L.66,840, 11s. 3d.

The value of the different kinds of stock from which the railway was made is according to the stock share list of 13th February 1855, as follows:—Original share, L.25 paid, L.5 now consolidated into capital stock; Granton preference, 4 per cent. do., L.20 paid, L.13, 15s.; preference, 4 per cent. do., L.5 paid, L.3, 2s. 6d.

The capital expended by the St Andrews Railway Company on the formation of that line was L.26,000. It is supplied with plant and worked by the Edinburgh, Perth, and Dundee Railway Company. The revenue for the year ending 31st January 1855 for 66,403 passengers was L.1826, 12s. 9d.; for 16,651 tons of goods, 9970 tons of coal, 1789 cattle, 2528 sheep, and 229 pigs, was L.1355, 3s. 11d.; together, L.3181, 16s. 8d.

The capital of the company which formed the railway from Thornton to Leven is L.28,000. It is supplied with plant and worked by the Edinburgh, Perth, and Dundee Railway Company, and the revenue and traffic corresponds with the capital expended, so far as it has yet been ascertained.

The great turnpike roads of the county, which are made and maintained by revenue collected at toll-bars, and the cross and bye roads by a tax on householders, on carriages, and on each plough-gate of land, are under the charge of parliamentary trustees, consisting of justices of the peace and commissioners of supply for the county, &c. The accounts of these trustees are printed and published annually. The only pontage or bridge tax levied in the county is that at the bridge over the Leven near the town of that name.

In all parts of the county the dwellings of the nobility, gentry, and agricultural labourers, and those of the other working classes, have been extensively renovated and rebuilt, and a great number of new houses and villages have been erected within the last fifty years.

The most ancient and celebrated buildings in the county are the tower of St Regulus, Cathedral, and Castle, at St Andrews, the Abbeys of Dunfermline and Inchcolm, the Palace of Falkland, the Castle of Ravenscraig, and Macduff's castle at East Wemyss. There are many others of less note.

The county contains thirteen royal burghs, with parliamentary privileges. St Andrews, Cupar, Anstruther Easter and Wester, Pittenweem, Crail, and Kilrenny, send one member to parliament; Kirkcaldy, Dysart, Burntisland, and Kinghorn send another; and Dunfermline and Inverkeithing join with Stirling, Queensferry, and Culross in electing a member to represent them.

The sixty-three parishes within the county are represented by another member.

These parishes form, for ecclesiastical purposes, the Synod of Fife, which is divided into four presbyteries, viz., the presbyteries of Kirkcaldy, Cupar, Dunfermline, and St Andrews.

Before these ecclesiastical divisions of the county (or kingdom of Fife, as it is sometimes called) were in general use for secular purposes, it was split up into petty shires, such as Lochoreshire, Dunfermlineshire, Gaitmilkshire or Kinglassie, Wemyss-shire, Kingornshire, &c., &c. It was also divided into regalities, constabularies, and baronies. A map showing these ancient divisions is at present in progress of construction by a learned antiquary, from the information contained in ancient charters.

The regality of stewartry of Fife forfeited to the crown at the condemnation of Murdo Earl of Fife, contained lands lying in no less than nineteen of the modern parishes: the other regalities were not so extensive.

The courts in the county for the trial of crime and civil suits consist—1. of the burgh courts, the magistrates of which have jurisdiction within their respective royalties or burgh territory only; 2. of the sheriffs' ordinary courts, which are held at Cupar and Dunfermline, and circuit small debt courts, which are held periodically at Kirkcaldy, Leven, Colinsburgh, St Andrews, Newburgh, and Auchtermuchty; 3. of the justice of peace courts for deciding claims for small debts and petty offences, &c.

The jails of the county are those of Cupar and Dunfermline.

The educational establishments are the parish schools and schools supported by private exertions in considerable number in every populous locality.

The university of St Andrews, and the schools endowed by Dr Bell, are noticed under St Andrews; and the schools endowed by the late Mr Robert Philp, merchant in Kirkcaldy, under Kirkcaldy.

From the population returns in 1851, it appears that the number of schools in Fife is 285, the children attending 23,145; the number of the Sabbath-schools is 183, and the number of children attending 14,753.

The number of places of worship is 199, and the number of attendants at public worship on the morning of Sunday the 30th of March 1851 were 50,622. Of these 21,274 belong to the Established Church, 12,728 to the United Presbyterian Church, and 13,083 to the Free Church.

The population of the county in 1801 was 93,743; in 1811, 101,272; in 1821 it was 114,550; in 1831 it was 128,800; in 1841, 140,140; and in 1851, 153,546.

FIFTH-MONARCHY-MEN, a sect of English fanatics during the Protectorate, who supported Cromwell's government, which they regarded as the commencement of the fifth monarchy, or that which should succeed to the Assyrian, the Persian, the Grecian, and the Roman, and in which Christ should reign with the saints on earth for a thousand years. See Britain, vol. v., p. 416.

FIGEAC, a town of France, capital of a cognominal arrondissement in the department of Lot, situated on the right bank of the Selle, 32 miles N.E. of Cahors. It is enclosed by an amphitheatre of wooded and vine-clad hills, but the town itself is ill built, and the streets are narrow and dirty. Many of the buildings are remarkable for their antique style. It was formerly surrounded by ramparts and ditches, but these were demolished in 1622, though remains of them still exist. Among the public edifices worthy of notice are the abbey church of St Sauveur, the church of Notre Dame du Puy, the Château de la Baleine. At the S. and W. extremities of the town are two obelisks called *les aiguilles*, octagonal in form, and upwards of 50 feet in height: they were used in former times as fire beacons to guide travellers by night. Champollion the archæologist was born here in 1790, and an obelisk has been erected to his memory near the river. Pop. (1851) 7197.

FIGUEIRA, a town of Portugal, province of Beira, stands on the north bank of the estuary of the Mondego, 24 miles W.S.W. of Coimbra, of which it is the port. It is a favourite bathing-place, and has an extensive export trade in salt, wine, oil, and fruits. The harbour is difficult of access for large vessels. Pop. 6500.

FIGUERAS, a frontier town of Spain, province of Gerona, and 20 miles W.N.W. of the town of that name. It is a straggling town, situated in a rich plain of olives and rice. The citadel is an irregular pentagonal structure on the principles of Vauban, and is considered one of the strongest fortresses in Europe. It was built by Ferdinand VI., and has accommodation, magazines, &c., for 16,000 men. The buildings inside the walls are all bomb-proof, and the natural adaptation of its situation has been so taken advantage of that trenches can scarcely be opened on any side, the ground being everywhere rocky. It has, however, been several times captured; as by the French in 1808, 1811, and 1823. Figueras has manufactures of leather and paper, and some trade with France. Pop. 8352.

FIGURE OF THE EARTH.

SECTION I.

INTRODUCTION.

The determination of the figure and dimensions of the earth is a problem of very great importance in astronomy, inasmuch as it is in reference to the earth's diameter that the distances of the planets from the sun and from each other are estimated. It is also a problem of very great interest and curiosity; and has accordingly attracted the attention of mankind since the earliest dawn of civilization.

There are two points of view under which this great question may be considered. The figure of the earth may be regarded as a fact to be determined by investigation and experience, like any other phenomenon or law of nature; in which case it is necessary to find, by the actual measurement and comparison of different portions of the terrestrial surface, the nature of its curvature, and the magnitude of its diameters. Under the second point of view, the question is one of pure theory. The earth may be regarded as a congeries of material particles, attracting each other with forces reciprocally proportional to their mutual distances, and endowed with a rotatory motion about a fixed axis; and the problem is to determine the form the whole mass would assume in virtue of the attractive and centrifugal forces by which the particles are impelled. Viewed in this light, the actual figure of the earth becomes one of the series of consequences resulting from the universal gravitation of matter, and depending on the same laws which regulate its motion in its orbit about the sun.

It would be a waste of time to inquire what were the notions of the figure of the earth which were or might have been entertained by its earliest and most ignorant inhabitants. A very slight attention to the most common phenomena renders the fact of its general roundness almost palpable to the senses. The uniform level appearance of the sensible horizon in every situation in which a spectator can be placed,—the depression of the circumpolar stars as he advances toward the south, and their elevation as he proceeds in a contrary direction,—the disappearance of a ship standing out to sea,—the projection of the earth as seen in a lunar eclipse,—and a number of other familiar appearances,—put the globular figure of our planet beyond all manner of doubt. Reasoning from such appearances, the earliest astronomers universally regarded the earth as a sphere; and their attention was solely directed, in their various measurements and computations, to ascertain its dimensions. Modern science has discovered that its figure deviates slightly from that of a sphere, being compressed or flattened at the extremities of its axis of rotation; and the object of the astronomer, at the present time, is to determine not only its dimensions, but also the exact amount of its compression.

Attempts to estimate the magnitude of the earth were made at a very early date; for Aristotle relates that the mathematicians prior to his time had found the circumference to be 400,000 stadia. But Eratosthenes appears to have been the first who entertained an accurate idea of the principles on which the determination of the figure of the earth really depends, and attempted to reduce these principles to practice. His results, in consequence of the imperfect data from which they were deduced, were very inaccurate; but his method is the same as that which is followed at the present day, depending, in fact, on the comparison of a line actually measured on the surface of the earth with the corresponding celestial arc. He had remarked, or been informed, that at Syene in Upper Egypt, on the day of the summer solstice, at noon, objects cast no shadows; whence he concluded that the sun was exactly in the zenith at mid-day. On the same day at Alexandria he observed the sun's meridional distance from the zenith to be 7° 12′, or a fiftieth part of the circumference. Then, assuming Syene to be exactly under the meridian of Alexandria (the error in this assumption was about 3°), and the distance between the two places, measured in a straight line, to be 5000 stadia, he had $5000 \times 50 = 250{,}000$ stadia for the whole circumference of the earth. It is easy to see how very imperfect this operation must have been. Without mentioning smaller errors, the neglect of the solar diameter would alone occasion an uncertainty as to the sun's declination, and consequently as to the length of the celestial arc, amounting to half a degree on the observation at Syene; and there is no reason to suppose that that at Alexandria was more exact. The terrestrial distance between the two places was assumed on equally, or probably still more loose and inaccurate determinations.

The next attempt to ascertain the dimensions of the earth was made by Posidonius. This astronomer adopted a method which differed from that of Eratosthenes only in determining the celestial arc by means of the altitude of a star, instead of the sun's zenith distance. At Rhodes the bright star Canopus, when on the meridian, barely appears above the horizon. At Alexandria the same star was observed to have a meridional altitude of a quarter of a sign, or seven and a half degrees, which, therefore, was the celestial arc intercepted between the zenith of Alexandria and Rhodes. The terrestrial distance between the two places was estimated, like that between Alexandria and Syene, at 5000 stadia, and they were both supposed to be under the same meridian. Hence, since seven and a half degrees is the forty-eighth of the circumference, we have $5000 \times 48 = 240{,}000$ stadia, for the whole circumference of the globe.

It is impossible to form any correct opinion of the degree of approximation attained in these ancient measures, as the length of the stadium is not known with any certainty. That it varied in different places, and at different times, is sufficiently obvious from the statement of Ptolemy, who, in his work on geography, assigns the length of the degree at 500 stadia, and consequently the whole circumference at 180,000, differing from the determination of Posidonius in the proportion of three to four, and still more from that of Eratosthenes. Ptolemy remarked that it was not necessary that the line measured should lie exactly in the meridian: it was sufficient to know its inclination to the meridian, or the azimuthal angle, together with the latitudes of its extreme points, in order to compare it with the meridional arc. The determination of the azimuth is, however, an operation of considerable difficulty; and Ptolemy has given no details of the method by which he proposed to estimate it. He has been equally silent in respect of the means by which the mean length of a degree was ascertained to be 500 stadia, so that the result which he has recorded is still less satisfactory than those of the two more ancient astronomers.

The active curiosity of the Arabians, which was exerted so successfully in promoting practical astronomy, did not

[1] Contributed by Thomas Galloway, 1836; and brought up to the present date (1855) by C. P. S.—*Ed.*

overlook the measure of the earth. The Caliph Almamoun, who began his reign in the year 814, ordered a company of astronomers to measure a degree on the level plain of Mesopotamia. Dividing themselves into two parties, the one proceeded northward, and the other southward, in the direction of the meridian, through a degree of latitude, and measured with rods the itinerary distance as they proceeded. The perfect agreement of their conclusion with that of Ptolemy throws it open to great suspicion; and when it is considered that their operation was repeated at a different place, with exactly the same result, there can be no doubt that they blindly adopted the statement of the Greek astronomer, either from inability to execute the task assigned to them, or because they had no confidence in their own determination.

From the time of Almamoun, the problem of determining the dimensions of the earth was neglected, till the revival of astronomy with general learning in Europe. The first attempt to solve it was made by Fernel, who, about the middle of the sixteenth century, measured the distance from Paris to Amiens along the high road, by observing the number of revolutions made by his coach-wheel in the journey between these two cities. Supposing them to be under the same meridian, which is nearly true, and having ascertained the difference of their latitudes, Fernel found by this means the length of the degree to be 57,070 French toises, or about 364,960 English feet. A degree was measured long afterwards at the same place by Lacaille, in a far more adequate and scientific manner, and he found it to be 57,074 toises. This agreement is rendered less extraordinary by the circumstance that the toise of Fernel was not exactly of the same length as that of Lacaille. After all, it must be allowed that Fernel made a fortunate guess. (Delambre, *Astronomie*, tom. iii. chap. xxxv.)

But the first who had the merit of attempting to execute the geodetic operations that are indispensably necessary to effect the accurate measurement of a long line on the surface of the earth, was Willebrord Snell, a native of Holland, and a teacher of mathematics. Having established a chain of triangles between Alkmaer and Bergen-op-Zoom, and observed the angles of each triangle by means of a quadrant of five and a half feet radius, he measured a base on the frozen surface of the meadows between Leyden and the village of Soeterwoud, and determined the distance between the two places by trigonometrical computation. The length of the degree which he found was 28,500 Rynland perches, or about 55,020 toises, which is about 2050 toises too small. This result was published by Muschenbroek, who in fact revised or calculated the observations from the original papers a century after the death of Snell.

Norwood in the year 1635 attempted to measure a degree in England nearly in the same manner as Fernel. He measured the distance between London and York along the public road, taking the bearings and reducing the direction to the meridian in a rough way. The difference of latitudes he found by observations of the solstice to be 2° 28′, and thence concluded the length of the degree to be 367,176 English feet. Like the measurement of Fernel, this has been found to be a much nearer approximation than the method employed would have led us to expect.

The application of the telescope to circular instruments gave a far higher degree of precision to geodetic operations. Picard, to whom practical astronomy is indebted for this capital improvement, was the first who measured an arc of the meridian with such precautions and care as the delicate nature of the operation requires. He twice measured with wooden perches a base of nearly seven English miles in length; and observed the angles of his triangles with a quadrant, having a telescope adapted to it with cross wires in its focus. He even calculated the error produced by the instrument being placed out of the centre of the station, and determined the zenith distance of a star in the constellation Cassiopeia with a sector, for the purpose of obtaining the differences of latitude. The distance between Amiens and Malvoisine was found to be 78,850 toises, and the difference of latitude 1° 22′ 55″, whence the result gave for the degree at Amiens 57,060 toises; but as the aberration and nutation were unknown at that time, and the refraction was not taken into account,—causes of error to which it is indispensably necessary to have regard,—a determination which agrees so nearly with the results of recent measures could only have arisen from a fortunate compensation of errors. In fact, his toise was somewhat shorter than that which has since been adopted as the standard; and the error occasioned by this circumstance nearly compensated that which was committed in determining the celestial arc, so that in recalculating all the observations, the degree is found to be very nearly the same as was found by Picard.

Hitherto geodetic operations had been confined to the determination of the magnitude of the earth; but a discovery made by Richer turned the attention of mathematicians to its deviation from the spherical form. This astronomer having been sent, by the Academy of Sciences of Paris, to the island of Cayenne in South America, for the purpose of determining the amount of terrestrial refraction and other astronomical objects, observed that his clock, which had been regulated at Paris to beat seconds, lost about two minutes and a half daily at Cayenne, and that, in order to bring it to measure mean solar time, it was necessary to shorten the pendulum by more than a line. This fact, which appeared exceedingly curious, and was scarcely credited till it had been confirmed by the subsequent observations of Varin and Deshayes, was first explained in the third book of the Principia, by Newton, who showed that it could only be referred to a diminution of gravity arising from one of two causes—a protuberance of the equatorial parts of the earth, and consequent increase of the distance from the centre, or from the counteracting effect of the centrifugal force, occasioned by the rotation of the earth. The former could not, on any reasonable supposition regarding the figure of the earth, be regarded as adequate to produce the effect; but the latter, which would produce a retardation of the pendulum at Cayenne in the ratio of the square of the sine of 6° to that of 49° (the respective latitudes of Cayenne and Paris), might amount to 1·46 seconds. This was the first direct proof that had been obtained of the diurnal rotation of the earth.

From this time the exact determination of the figure of the earth began to assume a degree of importance which had not formerly attached to it. The centrifugal force arising from the diurnal rotation completely set aside the idea of perfect sphericity. Newton, assuming that the earth had been originally fluid, and supposing its density to be the same throughout the whole mass, and supposing moreover that its constituent molecules attract one another in proportion to the inverse square of the distance, demonstrated that it would assume, in consequence of the rotation, the form of a spheroid flattened at the poles; and that the proportion of its equatorial to its polar axis would be 230 to 231. But the supposition of the equal density of the earth is obviously very improbable, and consequently the ratio of the equatorial and polar diameters must be different from that now mentioned. Newton erroneously concluded that if the density is greater in the interior of the earth than at the centre, the compression would be greater than in the case of a spheroid of equal den-

sity. This mistake was pointed out by Huygens, who, in order to determine the amount of the compression from theory, reasoned in this way. Suppose two tubes to be united at the centre of the earth, forming a right angle with each other at that point, and extending to the surface, one in the plane of the equator, and the other along the polar axis, and filled with a homogeneous fluid. Now the fluid contained in the polar branch exerts a pressure on the centre equal to the whole of its weight, while the pressure of that in the other tube will be diminished by the centrifugal force. The second column, therefore, if of the same length, will be less heavy than the first; and in order to restore the equilibrium, it is necessary that the equatorial tube shall have gained as much in length as it has lost in weight through the effect of rotation. Hence the sea in the equatorial regions must be higher, or at a greater distance from the centre, than the polar sea, and consequently the earth must have a flattened form. Calculating from the supposition that the density increases regularly from the surface to the centre, where it is infinite, Huygens found the ratio of the diameters to be that of 578 to 579. This investigation is given in his work *De Causa Gravitatis*, published in 1690.

The theoretical determinations of the form of the earth by Newton and Huygens were at variance with the results of geodetic operations that had been carried on in France under the superintendence of the first Cassini, from 1680 till 1716, for the purpose of making a geometrical survey of that country. Cassini found the degree of the meridian to the south of Paris to be 57,092 toises, while on the north of that city it was only 56,960 toises. This result led to the conclusion that the earth is a protracted spheroid, or elongated at the poles; a conclusion entirely inconsistent with the principles of hydrostatic equilibrium, and the deductions of Newton and Huygens. The question, however, was of too great importance to astronomy to be allowed to remain undecided. Accordingly, the Academy of Sciences of Paris determined to apply a decisive test, by the measurement of arcs at a great distance from each other. For this purpose some of the most distinguished members of their body undertook the measurement of two meridional arcs, one in the neighbourhood of the equator, and the other in a high latitude. In 1735 Godin, Bouguer, and La Condamine, proceeded to Peru, where they were joined by two Spanish officers, Don Georges Juan and Antonio d'Ulloa, and, after ten years of laborious exertion, they measured an arc of above three degrees, between the parallels of 2′ 31″ north and 3° 4′ 32″ south latitude. The other party, consisting of Maupertuis, Clairaut, Camus, Lemonnier, Outhier, and Celsius, were in some respects more fortunate, inasmuch as they completed the measurement of an arc near the polar circle, of 57 minutes, and returned to Europe within sixteen months from the period of their departure.

The measurement of Bouguer was executed with great care; and, on account of the locality (the extremities being on different sides of the equator), as well as the excellent manner in which all the details were conducted, it has always been regarded as a most valuable determination. The original base was measured twice, and the difference between the two measures was scarcely two and a half inches. A second base of 5259 toises was measured with the most scrupulous attention by Bouguer, Condamine, and Ulloa, near the southern extremity of the arc, and the result differed less than a toise from the length calculated from the triangles. The latitudes at the two extremities of the arc were determined by simultaneous observations of the same star with zenith sectors. In fact, as the nutation of the earth's axis was then unknown, and as a considerable time necessarily elapsed before a large instrument could be transported from one extremity of the arc to the other, the results of successive observations with a single instrument presented little accordance. By the simultaneous observations, the greatest deviation from the mean did not exceed three or four seconds.

In consequence of a misunderstanding that unhappily sprung up among the principal persons engaged in this memorable expedition, their operations were conducted separately, and we have accordingly three independent results, but all agreeing very nearly with each other. The first is that of Bouguer, who found, after the various reductions, the length of the degree of the meridian at the equator, and reduced to the level of the sea, to be 56,753 toises. Condamine found 56,749 toises, and the Spanish officers 56,768 toises.

The party of Maupertuis, though their labours were sooner completed, had also to contend with very great difficulties. At their departure from France they had hoped to find a sufficient number of stations among the small islands situated in the Gulf of Bothnia; but on their arrival it was found impracticable to carry on a triangulation among the islands, consequently they were obliged to penetrate into the forests of Lapland. They commenced their operations at Tornea, a city situated on the mainland near the extremity of the gulf, and which formed the southern extremity of their arc. From this place they carried a chain of triangles northward to the mountain of Kittis, lat. 66° 48′ 22″. Here they commenced the observations of latitude by observing the distance of their zenith from the star δ Draconis; and having obtained a sufficient number of observations, they returned to Tornea, to determine the latitude of their station there in the same manner. At Tornea they observed not only the star δ Draconis, but also α Draconis; and some doubt having arisen respecting the accuracy of the determination at Kittis, they again repaired to that station, to observe the last star there also. The amplitude of the celestial arc was found, by taking the mean of the observations, to be 57 29″·6.

It now remained only to measure a base, and thereby determine the terrestrial distance between Tornea and Kittis. This was accomplished on the frozen surface of the river, by two parties who measured separately, and the difference between their results amounted only to about four inches. From this it resulted that the terrestrial arc between Tornea and Kittis was 55,023 toises, giving 57,422 toises to the degree, and consequently exceeding the degree measured by Picard in France by 362 toises.

As all these determinations concurred in proving that the degrees of the meridian increase very sensibly in length from the equator to the high latitudes, no doubt could any longer be entertained that the earth is compressed at the poles. The operations of the two Cassinis in France alone gave results leading to an opposite conclusion; and it therefore became desirable to ascertain the cause of the anomaly. For this purpose Maupertuis and his former associates undertook the verification of Picard's operations; and it resulted from the remeasurement of the arc between Paris and Amiens that the degree was equal to 57,183 toises. But a more extensive series of operations was undertaken some time after by Cassini de Thury (the third of that name) and Lacaille. With a view to determine more accurately the variation of the degree along the French meridian, they divided the whole arc between Dunkirk and Collioure into four partial arcs, embracing about 2° each, by observing the latitudes at five different stations. While engaged in this measurement, they discovered that the toise which had been used by Picard was shorter by about a thousandth part of the whole than that

which formed their standard, and that his final results were accordingly too great by about a thousandth part. They also found the mean length of a degree between Paris and Bourges to be 57,071 toises; between Bourges and Rhodez only 57,040 toises; and between Rhodez and Perpignan 57,048 toises; thus showing on the whole a very sensible diminution as we proceed towards the south. The last portion which they examined was that between Paris and Dunkirk; and after a very careful determination of the latitudes, and the measurement of a base of verification near Dunkirk, they found the degree to be 57,084 toises, greater than any of the former, as ought to be the case on the hypothesis of a polar compression.

Another important operation was likewise undertaken by Cassini and Lacaille, namely, the measurement of a degree of a parallel of latitude. The place they selected was near the mouths of the Rhone, under the forty-third parallel. One of the observers took his station on the mountain Sainte Victoire, near Aix, and the other on Saint Clair, near Cette. On the tower of the church of Sainte Marie, a village situated between the two stations, a signal was made by firing a quantity of loose gunpowder; and the instant of the flash was noted by each of the observers. The difference of sidereal time thus determined was 7 minutes 33·25 seconds, corresponding to a difference of meridians of 1° 53′ 19″. The distance between the two stations, which was ascertained by triangulation, being reduced to the distance on the parallel intercepted between the two meridians (at the latitude of 43°½), was found to be 78,599·6 toises, whence the length of the degree was computed to be 41,618 toises. This exceeded by about 260 toises the length of a degree of the same parallel computed on the hypothesis of the earth's being a perfect sphere. The details of all these operations are given in the *Meridienne de Paris Vérifiée.*

About the middle of the last century several arcs of meridian were measured in various countries, which, though of inferior importance in comparison of the more extensive surveys which have since been undertaken, are nevertheless deserving of enumeration. In 1751 Lacaille measured an arc at the Cape of Good Hope, whither he had gone for the purpose of determining the lunar parallax, and making other astronomical observations. At the latitude of 33° 18½′ he found the degree of the meridian to be 57,037 toises. This result was nearly the same as had been obtained in France, 10° farther from the equator; and clearly proved either the existence of great local irregularities in the form of the earth, or the dissimilarity of the two terrestrial hemispheres. As theory recognised no such abnormal condition of figure, and on the other hand, Lacaille's observations, all the details of which had been preserved, appeared to have been carefully made and correctly computed, the result which they gave was for some generations a very *vexata quæstio* amongst all geodesists. After the lapse, however, of nearly a century, the arc has been lately remeasured under the auspices of the British government, with all the modern improved means and appliances; and an approximate calculation of the observations shows, that the greater part of Lacaille's anomaly was produced by *mountain attraction* on his plumb-line. (1855.)

In 1751 the measurement of a terrestrial arc was undertaken in the Roman states by the Jesuits Maire and Boscovich. It extended nearly two degrees, between Rome and Rimini, and it was found that the degree of meridian between these parallels, namely, 42° and 44°, contained 56,973 toises. The details are given at length by Boscovich, in a work of great elegance, and entitled *De Litteraria Expeditione per Pontificiam ditionem*, &c. Romæ, 1755.

Liesganig, a Jesuit, in 1762 also executed two measures of a meridional degree, one in Hungary and the other in the Austrian states; but it has been shown by Baron Zach, in his *Correspondence Astronomique*, vol. vii. that the results merit no confidence, and, in fact, would lead to certain error if employed as elements in determining the figure of the earth.

About the same time, in 1764, an arc of meridian was measured in North America, on the peninsula between the Chesapeake and Delaware bays, by two Englishmen, Charles Mason and Jeremiah Dixon. They employed no triangulation, but measured the line with deal rods along the whole extent of the arc, the mean latitude of which was 39° 12′. Their rods were afterwards compared with the five-feet brass rods made by Bird. The latitudes were determined with a zenith sector. The length of the degree, after the necessary corrections and reductions were made, was found to be 60,625 English fathoms, or 56,888 toises. There is no doubt that great care was bestowed on this operation; it is, however, easy to see that the measurement of so long a line by means of rods is liable to many causes of error from which the method of triangulation is exempt.

In 1762 Beccaria undertook to measure a degree in the plains of Piedmont. He found the degree of the meridian at the latitude of 44° 44′ to contain 57,468 toises; but great uncertainty remained respecting the correctness of the latitudes, the extreme points of the arc being in the near neighbourhood of immense ranges of mountains, which could not fail to produce a very considerable deviation of the plumb line. It was supposed that as both ends of the arc were terminated by mountain ranges, whereas Boscovich's arc had been carried across the Appennines and terminated at the sea coast, the errors of the two measures occasioned by the local attraction, being of opposite kinds, would neutralize each other, and give a correct mean result.

Amidst the rapid advances of mathematical science towards the end of last century, the determination of the figure of the earth was not overlooked. In the year 1783 a memorial was presented to the British government by Cassini de Thury, stating the important advantages that would result to astronomy and navigation, from having the difference of longitude of the Greenwich and Paris observatories determined by a geodetic measurement. Fortunately this proposal was agreed to. The English operations were placed under the superintendence of General Roy, who to active and indefatigable zeal united great skill and experience in practical astronomy and surveying. In the summer of 1784 a base of rather more than five miles was measured on Hounslow Heath. In the measurement of this base, deal rods were at first employed; but as these were found to warp, and be affected with the variations of the hygrometrical state of the atmosphere, glass tubes were substituted; and in 1791 the same base was measured with a steel chain carefully made by Ramsden, yet the difference from the former measure was found to be only three inches. The mean result was 27,404·2 feet reduced to the level of the sea, and the scale being taken at the temperature of 62° of Fahrenheit. A chain of 32 triangles, in connection with this base, extended over the country to Dover and Hastings; and two more, stretching across the channel, connected them with the French signals on the opposite side. The instruments employed in this survey were of the most excellent description, and far superior to any that had ever been employed in similar operations. The angles of each triangle were measured by a large theodolite constructed by Ramsden; and it was this splendid instrument that first exhibited the *spherical excess*, or the minute quantity by which, on ac-

count of the sphericity of the earth, the sum of the three angles of a triangle on the earth's surface exceeds 180°.

The French part of this great operation was conducted with equal ability by Cassini (the fourth of that name), Mechain, and Delambre. The angles were measured with the repeating circle of Borda; an instrument of a very different description from the theodolite, but which in geodetic operations may fairly be allowed to give, if not equally, at least sufficiently correct results, while in practice it is much more commodious. The result of the combined measures showed the meridian of Paris to be 2° 19′ 51″ east of Greenwich, or 9″ less than had been determined by Dr Maskelyne.

Soon after this time a series of geodetic measurements was commenced both in France and England, which, in point of extent, as well as minute accuracy, far surpassed all the operations which had yet been undertaken with a view to determine the figure of the earth. In 1791 the National Convention of France having agreed to remodel the system of weights and measures, determined to adopt a standard taken from nature, which might be universally applicable in all countries, and capable of being restored in any future age, if by accident it should happen to be lost. Two such standards were proposed,—namely, the length of the pendulum, which makes a given number of vibrations in a given latitude; and the quadrant of the terrestrial meridian. Of these the pendulum is by far the most easy to be determined; but it was objected, that as the length of the pendulum varies at different latitudes, and also depends in some degree on the geological character of the country where it is measured, its length, if it should happen to be lost, could not be recovered, without knowing the precise place at which it had formerly been determined. The length of the quadrant of the meridian is, however, invariable, and, if the earth is a regular spheroid of revolution, must be the same at all places. Accordingly, the Convention chose the ten millionth part of the meridian from the equator to the pole as the unit of their new scale; and in order that this unit might be determined with the greatest possible precision, it was resolved to remeasure the arc of the meridian of Paris, and to extend it from Dunkirk to Barcelona, a distance comprehending altogether an arc of about nine degrees. The practical execution of this undertaking was confided to two astronomers of distinguished ability, Delambre and Mechain, by whom the requisite operations were carried on during the years 1792, 1793, and 1794, amidst all the dangers and difficulties arising from the disorganized state of the country, with a resolution and courage of which the annals of science afford few examples. The triangles amounted to 115 in number. Each of the three angles of every triangle was separately observed with the repeating circle. The different observations, with the original registers and remarks of the observers, were compared by commissioners, among whom were some of the ablest men in France. A form was drawn up, after which all the calculations were made. The calculations of the triangles, as well as of the azimuths, were examined by Tralles, Van Swinden, Legendre, and Delambre himself. The triangles were connected in the neighbourhood of Paris with a base of upwards of seven miles in length, being 6075·9 toises, at the temperature of 16¼ centigrade, or 61¼ of Fahrenheit. A base of verification of 6006·25 toises was measured by Mechain, near Perpignan, at the southern extremity of the arc; and the measured length was found to differ by less than a foot from the length deduced by calculation from the first base, though the distance was more than 436 miles. A line of this length, measured with extreme precision, is obviously quite sufficient to enable us to infer, with all the requisite exactness, the length of the quadrantal arc; but the French astronomers resolved to extend the triangulation still farther. Accordingly, Mechain repaired again to Spain, and in the year 1805 continued the chain of triangles from Barcelona to Tortosa, on the coast of the Mediterranean. At this place his labours were prematurely terminated by an epidemic fever The prolongation of the arc was, however, committed to two philosophers of distinguished reputation, Biot and Arago. An immense triangle, one of the sides of which exceeded 100 miles, connected the coast of Valentia with the island of Iviza, which was joined by another triangle with Formentera, distant no less than 12° 22′ 13″·39 from Dunkirk, the northern extremity of the arc. The result of the whole gave a value of the quadrantal arc, differing somewhat from that determined by Delambre and Mechain, but so little that the length of the metre would be scarcely affected by four times the millionth part of itself. The details of this magnificent operation are given at length in the four volumes of the *Base Metrique.*

The English survey, which had been interrupted by the death of General Roy in 1790, was resumed in 1793 under the direction of Colonel Mudge. The original triangles between Greenwich and Dover were extended along the coast to Dunnose in the Isle of Wight, and thence through Devonshire and Wiltshire, and connected with a base of verification measured on Salisbury Plain. The length of this base was found, after the proper reductions, to be 36574·4 feet, differing scarcely one inch from the length deduced by calculation from the base on Hounslow Heath. So near a coincidence, though probably owing in some degree to a compensation of errors, affords a convincing proof of the extreme accuracy with which every part of the operation had been conducted. In 1802 the triangulation was carried into Yorkshire, and a meridian arc measured from Dunnose to Clifton. The latitudes at the terminal points were determined with Ramsden's zenith sector. The arc was afterwards extended to Burleigh Moor, and has since been carried to the Shetlands. It may be remarked that both the French and English arcs present this singular anomaly, that when portions of them, at particular places, are considered separately, the length of the degree appears to increase on going southward.

The survey has been continued, with occasional interruptions, up to the present time, under the able direction of Lieutenant-Colonel Colby;[1] and the triangulation has been carried to the remotest parts of Scotland, and over a considerable part of Ireland. In the course of the operations, several important improvements, both in respect of the instruments employed, and in the method of conducting geodetic measurements in general, have been introduced into practice. A base of upwards of seven miles has been measured near Londonderry; and it now only remains to determine the latitudes of some stations, to give us the elements of a new and greatly prolonged arc.

In the years 1801, 1802, and 1803, Maupertuis' Swedish arc was re-measured by Svanberg, and extended nearly 40′ in amplitude. The methods were the same as had been employed by Delambre. The extremities of the new arc were at Mallörn and Pahtawara. The distance was found to be 92,778 toises, and the difference of the latitudes 1° 37′ 20″·3; whence 1° = 57,196 toises. This agrees much better than the result of Maupertuis (57,422 toises) with other measures; but the difference, which implies an error of 12″ in the latitude of Kittis as determined by the French academicians, has not been satisfactorily accounted for; so that there is still some doubt about the length of the degree in that latitude. (See Svanberg's *Exposition des Operations faites en Lapponie,* &c. Stockholm, 1805.)

Since the beginning of the present century, two arcs of

[1] Since this article was written, Col. Colby has been succeeded by Col. Hall, and still more lately by Major James. (1855.)

Figure of the Earth.

meridian have been surveyed in India. The first was in the neighbourhood of Madras, and comprehended only 1° 35′. The second, however, is the longest which has yet been measured. The first, and a large part of the second, was accomplished under the direction of Colonel Lambton; and the instruments and methods of observation and calculation were exactly the same as those that had been employed by Colonel Mudge in the English survey. The southern extremity of the second arc was at Punnæ, near Cape Comorin, latitude 8° 9′ 32″·51; and the northern at Daumergidda, latitude 18° 3′ 16″·07. The amplitude is consequently 9° 53′ 43″·56, and the distance between the extremities was found to be 598,629·98 fathoms (about 680 miles), giving 60,495 fathoms, or 362,970 feet, for the length of the degree. Several bases were measured, and the whole of the operations appear to have been conducted with great skill and accuracy. This arc has since been extended by Captain Everest to Kaliana, latitude 29° 30′ 48″·8; so that the whole length now includes more than twenty-one degrees. The details of Colonel Lambton's operations are given in the different volumes of the *Asiatic Researches* (see vols. viii., x., xii.), and those of Captain Everest, in his "*Account of the Measurement of an Arc of the Meridian between the Parallels of* 18° 3′ *and* 24° 7′," printed at the expense of the East India Company.[1]

Various geodetic operations on a less extensive scale have been recently executed, which are better adapted, perhaps, to give information respecting the local curvature than the general form of the earth. Beccaria's arc has been remeasured by Plana and Carlini: the results clearly demonstrate the existence of some errors in the original measurement, but they are not yet altogether satisfactory, and the country is very unfavourable. The distance between Göttingen and Altona has been measured by Gauss; and the amplitude of the corresponding celestial arc is known with the utmost precision, from observations of the latitude made at the respective observatories of the two places. The amplitude, however, is only about two degrees, and there is some doubt about the exact length of the iron bars with which the base was measured. A more extensive arc has been measured in Russia by Struve. It extends at present to three and a half degrees, and it is understood that it is in contemplation to prolong it still farther.[2] Many new methods have been employed in this measurement; and it acquires additional value from its high latitude, and the acknowledged skill and accuracy of the observer.

The above are the principal arcs of meridian, but some arcs of parallel have also been measured. Theoretically speaking, the figure of the earth may be determined from the measurement of arcs of parallel, as readily as from meridional arcs; and the geodetical operations in the one case differ in no respect from those in the other. But the great, and, we fear, insurmountable difficulty, is to determine with sufficient precision the difference of astronomical longitudes. In a subsequent part of this article we shall have again occasion to mention Cassini's measurement of an arc of parallel across the mouth of the Rhone; of the English arc between Beachy Head and Dunnose; and that recently made from Marennes to Padua.

The problem of determining the earth's figure from the laws of hydrostatic equilibrium has not yet received the complete solution which the present advanced state of analytical science might lead us to expect. We have already mentioned the results found by Newton and Huygens. Maclaurin first demonstrated that the ellipsoid of revolution is a figure which satisfies the conditions of equilibrium in the case of a revolving homogeneous body, whose particles attract one another according to the law of the inverse square of the distance; and he moreover determined the amount of the attraction in a particle situated anywhere on the surface of such a body. This was an important step towards the solution of the problem. A few years afterwards, Clairaut published his *Théorie de la Figure de la Terre*, which, among other results, demonstrated with uncommon elegance, contained a very remarkable theorem which establishes a relation between the oblateness of the earth and the variations of gravity at different points of its surface, and consequently gives the means of determining the earth's figure by means of observations of the length of the seconds pendulum at different latitudes. Maclaurin's discovery gave the intensity of the gravitating force on the surface of the spheroid, or in its interior; but it was necessary to assign the force with which an exterior point is attracted. This was partly accomplished by D'Alembert, who proved that the attraction of any ellipsoid whatever upon a point situated in the prolongation of one of its axes, is to the attraction of a similar spheroid having the same centre, and passing through the attracted point, as the mass of the first spheroid is to the mass of the second. Legendre found an approximate expression by means of series, for the attraction on a point placed anywhere without a spheroid of revolution; and Laplace extended the solution to ellipsoids in general. But the complete solution was reserved for Mr Ivory, who obtained in finite terms a very simple expression for the attractive force of an ellipsoid on an exterior point, and thereby completed the theory of Maclaurin. It may be stated in a general way, that notwithstanding all the researches that have been made respecting this very intricate subject, the only positive results which theory has yet supplied are the three following:—1*st*, Maclaurin's demonstration that a homogeneous mass revolving about an axis will be in equilibrio with the figure of an ellipsoid of revolution; 2*d*, Clairaut's theorem for determining the ellipticity by means of pendulum observations; and, 3*d*, the expression for the attraction of ellipsoids on exterior particles, found by Mr Ivory. A complete theory would determine whether there are or are not other figures besides the ellipsoid, under which the equilibrium could subsist; but this has not yet been accomplished. Indeed it has not even been proved that the sphere is the only figure which could be assumed by a body at perfect rest, and whose molecules are subjected to no other forces than their mutual attractions.

Our limits do not permit us to enter into details respecting the numerous experiments that have been made of late years to determine the figure of the earth by measuring the variations of gravity at different places by means of the pendulum. The most valuable series of observations of this kind we yet possess are those of Captain Foster, reduced under the direction of Mr Baily, and published in the *Memoirs of the Royal Astronomical Society*, vol. vii. But a discovery recently made by Bessel proves that less accuracy has been obtained by this method than was supposed. It has been found, that a pendulum, when vibrating, drags along with it a portion of air, the precise effect of which can be ascertained in no other way than by actual experiment in vacuo with each individual pendulum. The probable correction which it would be necessary to apply to the results that have already been found, cannot be satisfactorily determined.

The mean of the pendulum experiments gives rather a higher value of the ellipticity than the results of geodetic measures; but there are many elements, particularly the irregular constitution of the exterior crust of the earth, and the density of the strata surrounding the station, which can scarcely be determined, and which yet affect materially the results of the experiments. This subject will be resumed under the article PENDULUM.

[1] See some account of this great work in Dissertation VI., chap. iii., sect. 4. (1855.)

[2] See as above.

Figure of the Earth.

Besides the methods which have now been alluded to, physical astronomy furnishes other means of arriving at a knowledge of the figure of the earth. The precession of the equinoxes, and nutation of the earth's axis, are phenomena depending on the compression of the earth; and as their amount is now ascertained, from astronomical observations, with the utmost accuracy, we can reciprocally deduce from them a knowledge of the compression. They do not, however, give us an absolute value of the amount of compression, but they make known the limits within which it must necessarily be confined. These limits are $\frac{1}{279}$ and $\frac{1}{578}$. But a more delicate measure of the same element is furnished by some irregularities in the moon's motion to which it gives rise; and as the lunar theory has now attained a very high state of perfection, and as the small irregularities which cause so much perplexity in geodetical measures here entirely disappear, this is perhaps the most satisfactory method of all of determining the ellipticity of the earth. The equations into which the irregularity in question enters were discovered by Laplace; and the ellipticity necessary to produce the observed effect was found, on calculation, to be $\frac{1}{304}$; confirming in a most remarkable manner the deductions from the measurement of arcs and the observations of the pendulum.

SECTION II.

OF THE MEASUREMENT OF TERRESTRIAL ARCS.

The determination of the figure of the earth, being founded on the comparison of lines actually measured on its surface with the corresponding arcs of the celestial sphere, requires a combination of geodetical and astronomical operations, which it will be our object in the present section to explain. Theoretically considered, the geodetical line to be measured may lie in any direction, because it can always be reduced to the meridian or to any other given direction; but, for practical reasons, which will be pointed out hereafter, it ought to be taken, as nearly as the nature of the country in which the measurement is made will permit, either in the direction of the meridian, or of a parallel of latitude. Differences of latitude, however, can be determined with greater precision than differences of longitude; the meridional arcs are consequently the best adapted to the purpose. Satisfactory results can only be obtained from the measurement of lines of very considerable length, for example, of several degrees; and this circumstance renders the geodetical operations both laborious and complicated. In no place of the world, probably, and certainly in no populous country, could it be possible to find a territory so free from obstructions as to admit of the direct measurement of a line of two or three hundred miles in the same direction. Hence, when an operation of this nature is to be undertaken, the country in which the direction of the line to be measured lies is divided into triangles; the angles of each triangle are accurately observed with a theodolite, or some other equivalent instrument; and the side of one of them being actually measured, all the other sides are computed from it by the rules of trigonometry. In this manner the length of the whole line is ascertained, and on comparing it with the celestial arc, the data are obtained for deducing the dimensions and form of the earth.

It appears, then, that in order to determine the figure of the earth by the measurement of degrees, four distinct sets of operations are necessary: 1*st*, The measurement of one side of a triangle, or of *the base* as it is called; 2*d*, the observation of the angles of each triangle, together with the height of the station, in order that the triangles may be reduced, if necessary, to the horizontal plane, and to the level of the sea; 3*d*, the observation of the *azimuths* of the sides of the triangles, or the angles they make with the meridional line; 4*th*, the latitudes of the extreme points of the line. It is immaterial in what order these operations are undertaken. We shall begin with the measurement of the base.

The length of the base must be regulated in some degree by the nature of the locality; but being the fundamental element from which the sides of all the triangles are deduced, it should not be less than five or six miles. A piece of ground must therefore be selected, as nearly level as possible, and admitting a line of that length to be described on it. The direction of the base is first marked out by pickets; and, in order to place these in the same straight line, or rather in the same vertical plane, a telescope, mounted in the manner of a transit instrument, is set up at one extremity, by means of which the observer is enabled to direct an assistant, by signals, to the exact position in which the picket is to be placed, and also to bring their tops exactly into the same level. As a farther guide, a rope may then be stretched between the pickets; and, for greater security in the subsequent operations, the whole extent may be approximately measured by rods or chains, in the usual manner. The extremities of the base ought to be permanently marked by points. The centres of metal tubes, cannon for example, let into the ground to a considerable depth, answer this purpose very conveniently.

These preliminary operations being accomplished, the next step is to proceed to the more delicate operation of measuring the exact distance between the terminal points, or extremities of the base.

Various methods have been practised for this purpose. In the measurement of the first base of the trigonometrical survey on Hounslow Heath by General Roy, deal rods were at first employed, as had been done in almost all previous measures; but though every precaution was used in selecting the best seasoned timber, and every means employed to secure the rods from flexure, it was discovered, in the course of the operations, that they were liable, from variations in the state of the atmosphere as to moisture or dryness, to sudden and irregular changes of such magnitude as to destroy all confidence in the results. They were therefore laid aside; and glass rods, consisting of straight tubes twenty feet in length, and about an inch in diameter, and enclosed in wooden cases, were substituted. The only alteration to which these were subject arose from the expansion and contraction from variations of temperature; and as such alterations follow constant and ascertainable laws, their effects could be easily computed, and a correction made for them. But the apparatus ultimately adopted, both in the measurement of this base, and the other bases subsequently measured for the purpose of verifying the operations in the English survey, consisted of two steel chains, made with great care by Ramsden, of a hundred feet in length, and composed each of forty links, joined in the manner of a watch chain. The chains were supported by deal coffers, and after being placed in a straight line, were stretched with a weight of fifty-six pounds. Their temperature and inclination to the horizon were carefully noted at the same time, and the proper corrections subsequently made.

This method has been objected to, on account of the uncertainty of giving the chain always the same degree of tension, and of the rubbing and wear of the joints; but the best proof of the accuracy of the results obtained by it consists in the fact, that the two measurements of the base on Hounslow Heath, first by glass rods, and secondly

by the steel chains, differed from each other, after all the reductions were made, by less than three inches, although the whole length exceeded five miles. For an account of the comparison of the chains with one another, and with the standard brass yard made by Ramsden, we must refer to the *Philosophical Transactions*, vol. i.

The use of chains has been confined to the English and Indian surveys. For the determination of the meridian of Dunkirk, Borda employed rules of platina, exactly two toises in length, and furnished with a very ingenious contrivance for ascertaining the expansion. Along one side of the rule there was a slip of brass, firmly fixed at one extremity, but at liberty to move along the rule at the other end, according to the relative expansion of the two metals. The relative expansion being read off by means of a micrometer, gave a ready means of computing, from tables previously constructed, the absolute expansion of the platina rule. Four rules were made use of, three of which were always placed on the ground at once; and in order to prevent any derangement, they were not brought into absolute contact. A small interval of a few millimetres was left between them, which was measured by means of a slider attached to the preceding end of each rule, and which was pushed out till it came into contact with the following end of the preceding rule. See Delambre, *Astronomie*, tome iii. p. 538, or *Base du Systême Metrique*.

Various other contrivances have been used for the measurement of the base line. MM. Plana and Carlini, in the re-measurement of Beccaria's arc, employed measuring rods of wood, twelve metres in length, of the form of hollow parallelepipeds. For the Hanoverian base measure, between Altona and Gottingen, Gauss employed three rods of hammered iron each twelve French feet in length. But the most ingenious apparatus which has yet been invented for this purpose, is that which was made by our celebrated artist Troughton for the Irish base. As this instrument is probably destined to supersede all others previously used, we shall briefly describe the principle on which it is constructed.

Let AB and DE (Plate CCLVII. fig. 1) represent two bars of different metals, firmly united to a transverse bar at the middle C, but entirely free to move independently of each other at the extremities, according to their different expansions. AP and BQ are two tongues of steel attached to the extremities of the two rods AD and BE, by double conical joints, around which they are capable of making a small angle with the lines perpendicular to AB or DE. At a certain given temperature the bars are exactly of the same length, when, consequently, AP and BQ are parallel to each other, and perpendicular to the bars. Let us now conceive the bars to receive an increase of temperature, and that the dilatation of AB is greater than that of DE. In consequence of the increased temperature, both bars will be lengthened, but their lengths will no longer be equal; consequently the two tongues AP and BQ will no longer be parallel; for, suppose AB to become *ab*, and DE to become *de*, then AB being by hypothesis a more expansive metal than DE, *ab* will be longer than *de*, and the steel tongues will take the positions *ax* and *by*, inclined to each other. But if the point P is taken at such a distance from the bars that PA is to PD in the ratio of the dilatation of AB to DE, then in the new position *ax*, the point P will not sensibly deviate from the perpendicular AP, at least for moderate variations of temperature. In the same manner, the point Q will not sensibly deviate from its first position in the perpendicular BQ, so that the distance between P and Q remains sensibly the same. It is easy, however, to see that the dilatation of the bars must be confined within narrow limits; for, as the length of the tongue is invariable, P will not be found exactly in the line AP after the expansion has taken place; it will be on the same side of AP on which are the points a and d, and its distance from AP will be accurately measured by the quantity AP $\times$ (tan. APa — sin. APa); and as the same thing takes place with regard to Q, the distance between P and Q will be increased by twice this quantity. But as the angle APa must in all cases be extremely small, the difference between its tangent and its sine is altogether inappreciable. It is unnecessary to remark, that the same consequences (*mutatis mutandis*) take place when the temperature falls below the assumed standard.

In the instruments made use of in the measurement of the Irish base, the bar AB was of brass, and DE of iron. The length of each was ten feet, and the distance between them two inches. The length of the tongue is hence easily found from the relative dilatation of the two metals. Suppose the expansion of brass to be to that of iron in the ratio of 83 to 53 for an increase of 1° of temperature, and let PD $= x$ inches, we shall have $x : x + 2 = 53 : 83$; whence $x = \frac{53}{15} = 3\frac{1}{2}$ inches very nearly. But the precise position of the points P and Q must be determined by actual experiment: for the expansion or contraction of no two bars, even of the same metal, are ever found to be exactly the same.

In practice, five or six sets of bars, constructed in the manner now described, and placed in strong deal boxes supported on trestles, are laid along the line to be measured, and accurately levelled. They are placed at a small distance from each other, and the distance between the dots on the adjacent steel tongues of two succeeding bars is accurately measured by an ingenious micrometrical apparatus constructed so as to form a compensating instrument of exactly the same nature as the measuring bars.

The conception of this elegant apparatus belongs to Lieutenant-Colonel Colby; and the practical results it gives correspond with its theoretical excellence. It is computed that the greatest possible error of the base measured on the eastern shore of Lough Foyle, in the county of Londonderry, cannot exceed two inches, though the length is very nearly eight miles.[1]

The reduction to the level of the sea is made as follows: Let $r =$ radius of earth, $x =$ height above the level of the sea, $a =$ measured length of the base, and $a' =$ its reduced length; then

$$a' = a\left(\frac{r}{r+x}\right) = a\left(\frac{1}{1+\frac{x}{r}}\right) = a\left\{1 - \frac{x}{r} + \left(\frac{x}{r}\right)^2 -, \&c.\right\}$$

a series of which all the terms after the second may be neglected, by reason of their smallness.

It is easy to see, that as the base is not, correctly speaking, a straight line, but an arc of a circle, or rather ellipse, the sum of the lengths of all the rods or chains horizontally applied to it is not precisely the length of the arc, but of the circumscribing polygon. In order to determine how far this circumstance can affect the result, let us suppose the length of the measuring rod to be ten feet; when laid on the ground, exactly in the horizontal plane, it forms two tangents to the surface, of five feet each, and therefore each half length of the rod ought to be diminished by the difference between the tangent whose length is five feet, and the arc to which it belongs. Let A be the arc, then (ALGEBRA, Sect. XXV. H. 2)

[1] The three last bases measured in India, on which the northern half of the great meridional arc depends, were measured with an apparatus exactly similar. On the Cape arc, Colonel Colby's own bars were employed, having been sent for that purpose from Ireland, and the several parts of the base being compared with each other by triangulation, indicated a probable error of only 0·25 of an inch. (1855.)

$$\frac{A}{r} = \frac{\tan. A}{r} - \frac{1}{3}\frac{\tan. A^3}{r^3} + \&c.$$

whence $\tan. A - A = \frac{1}{3}\frac{\tan. A^3}{r^2} = \frac{125}{3r^2}$.

This must be multiplied by the number of times that the half rod, or five feet, is contained in the whole base. Supposing the base to be five miles, or 5280 times the length of the half rod, and the radius of the earth to be 4000 miles, or 4000×5280 feet, we should have $\tan. A - A = \frac{125}{3 \times 4000^2 \times 5280}$ feet; a quantity which is altogether insensible.

We come now to the triangulation. The first thing to be done is to select proper stations for the vertices of the triangles. The selection will necessarily depend on the nature of the country through which the survey is made; but there are certain principles which ought to be observed, as nearly as the circumstances will permit. The stations should be chosen so that each angle of the principal triangles should approach as nearly as possible to 60°, because a small error in the estimation of a very acute or obtuse angle will greatly affect the length of the opposite side computed from it. Excepting in unavoidable cases, no angle ought to be less than 30°. The sides cannot be too long, while the signal at one extremity is visible from the other. The signals may be towers, spires, or other conspicuous objects conveniently situated; but such signals can seldom be well bisected by the wire of the telescope. Flag-staffs are better when the distances are not too great. Delambre preferred signals erected on purpose. They were generally constructed of wood, and of the form of a truncated pyramid. One considerable advantage arises from the use of signals constructed in this manner, namely, that the instrument can be placed exactly at the centre of the station. Frequently Bengal lights, reverberating lamps, and white lights, are employed; but these of course can only be seen during the night. The best signal of this sort was invented by Lieutenant Drummond. It is formed by directing a stream of hydrogen gas on a small piece of ignited quicklime; an intense light is produced, which may be seen at very great distances. Care should be taken to place the signals, if they are to be observed by day, in such positions that they may be projected on the sky; if projected on forests or mountains, they will seldom be distinctly visible. Svanberg constructed his signals with openings, to permit the light of the sky to be seen through them.[1]

The triangles being marked out, and the signals prepared, the next object is to measure the angles. When the theodolite is used for this purpose, no correction is required on account of the different altitudes of the signals, the reduction being effected by the instrument itself; but when a sextant or repeating circle is employed, the observed angles must be reduced to the plane of the horizon.

Let P, Q, and R (fig. 2) be the three stations, PQR the observed angle oblique to the horizon; produce PQ and PR till they meet Q′ R′, a line parallel to the plane of the horizon; through Q′ R′ let a plane be conceived to pass parallel to the horizontal plane, meeting PZ, the vertical passing through P, in P′; then Q′ P′ R′ is the horizontal projection of QPR, and the angles ZPQ, ZPR are the complements of the inclinations of the line PQ and PR to the horizon.

With P as a centre, and a radius = 1, let a sphere be described, intersecting PZ, PQ, and PR in the points A, B, and C respectively; the angle BAC is evidently equal to the horizontal angle Q′P′R′. Now, in the spherical triangle ABC, we have given by observation the side AB = the zenith distance of Q, AC = the zenith distance of R, and BC the oblique angle at the centre of the station, from which we are to find the angle BAC = Q′P′R′.

Let BC = a, AC = b, AB = c, and BAC = A. By a well-known formula of spherical trigonometry,

$$\cos. A = \frac{\cos. a - \cos. b \cos. c}{\sin. b \sin. c}; \text{ but } \cos. A = 1 - 2\sin.^2 \tfrac{1}{2} A,$$

$$\text{therefore } 2\sin.^2 \tfrac{1}{2} A = 1 - \frac{\cos. a - \cos. b \cos. c}{\sin. b \sin c},$$

$$\text{and } 2\sin.^2 \tfrac{1}{2} A = \frac{\cos. (b-c) - \cos. a}{\sin. b \sin. c}.$$

Now, if p and q denote two arcs, we have (ALGEBRA, XXV. D),

$$\cos. p - \cos. q = -2\sin. \tfrac{1}{2}(p+q)\sin. \tfrac{1}{2}(p-q),$$

therefore

$$\cos. (b-c) - \cos. a = -2\sin. \tfrac{1}{2}(a+b-c)\sin. \tfrac{1}{2}(b-c-a) = 2\sin. \tfrac{1}{2}(a+b-c)\sin. \tfrac{1}{2}(a-b+c),$$

and the equation becomes

$$\sin.^2 \tfrac{1}{2} A = \sin. \frac{\tfrac{1}{2}(a+b-c)\sin. \tfrac{1}{2}(a-b+c)}{\sin. b \sin. c}$$

Let $\frac{1}{2}(a+b+c) = s$; then $\frac{1}{2}(a+b-c) = s-c$, and $\frac{1}{2}(a-b+c) = s-b$; consequently

$$\sin. \tfrac{1}{2} A = \left(\frac{\sin. (s-c)\sin. (s-b)}{\sin. b \sin. c}\right)^{\frac{1}{2}}$$

From this formula the value of A is easily computed, when the inclinations of the lines PQ and PR to the horizon are not very small. In practice, however, it frequently happens that these inclinations are very small, or that the angles b and c differ very little from right angles. When this is the case, the logarithmic calculation of the formula becomes troublesome, particularly if it is required to determine A with great exactness; and it is better to adopt a different method of proceeding.

Instead of seeking to find the projected angle Q′P′R′, we may find its difference from the observed angle QPR, which difference will seldom amount to more than a few seconds. Since the arcs b and c are supposed to differ little from 90°, if we make $b = 90° - \beta$, $c = 90° - \gamma$, the angles β and γ will be very small. Substituting these values of b and c in the formula

$$\cos. A = \frac{\cos. a - \cos. b \cos. c}{\sin. b \sin. c}$$

it becomes

$$\cos. A = \frac{\cos. a - \sin. \beta \sin. \gamma}{\cos. \beta \cos. \gamma};$$

but

$$\sin. \beta = \beta - \frac{\beta^3}{6} + \&c., \sin. \gamma = \gamma - \frac{\gamma^3}{6} + , \&c.$$

$$\cos. \beta = 1 - \frac{\beta^2}{2} + \&c., \cos. \gamma = 1 - \frac{\gamma^2}{2} + , \&c.$$

therefore, on substituting, and rejecting all terms above those of the second order, we have

$$\cos. A = \frac{\cos. a - \beta\gamma}{1 - \frac{1}{2}(\beta^2 + \gamma^2)} = \cos. a - \beta\gamma + \tfrac{1}{2}(\beta^2 + \gamma^2)\cos. a.$$

Let A = $a + x$. It is evident that when β and γ both vanish, x also vanishes, and we get A = a. Hence if β and γ be both very small, x is also very small, and consequently we may suppose its cosine = 1, and its sine = x. In this case $\cos. A \left\{= \cos. (a + x)\right\} = \cos. a \cos. x - \sin. a \sin. x$ becomes

$$\cos. A = \cos. a - x \sin. a.$$

Equating this with the former value of cos. a, we get

$$x \sin. a = \beta\gamma - \tfrac{1}{2}(\beta^2 + \gamma^2)\cos. a$$

whence

$$x = \frac{\beta\gamma - \frac{1}{2}(\beta^2 + \gamma^2)\cos. a}{\sin. a}.$$

[1] The best signal of all, and that which has been generally employed on the Irish, and later portions of the Indian surveys, is the Heliostat or Heliotrope, in which the sun's rays reflected from a plane mirror are passed through an aperture in a vane plumbed exactly over the centre of the station, the appearance produced at a distance is exactly that of a bright star. An aperture of 2 inches was found sufficient for a distance of 30 miles, and the signal has been employed at distances of 100 and upwards. (1855.)

Figure of the Earth.

In order to adapt this fraction to logarithmic computation, let both its numerator and denominator be multiplied by 2; then, because $\cos. a = \cos.^2 \frac{1}{2}a - \sin.^2 \frac{1}{2}a$, and $2\beta\gamma = 2\beta\gamma \cos.^2 \frac{1}{2}a + 2\beta\gamma \sin.^2 \frac{1}{2}a$, we find, on multiplying and reducing,

$$2\beta\gamma - (\beta^2 + \gamma^2) \cos. a = (\beta + \gamma)^2 \sin.^2 \tfrac{1}{2}a - (\beta - \gamma)^2 \cos.^2 \tfrac{1}{2}a;$$

but $\sin. a = 2 \sin. \frac{1}{2}a \cos. \frac{1}{2}a$; therefore, by substitution,

$$x = \left(\frac{\beta+\gamma}{2}\right)^2 \tan. \tfrac{1}{2}a - \left(\frac{\beta-\gamma}{2}\right)^2 \cot. \tfrac{1}{2}a.$$

Here the arcs x, β, γ are expressed in parts of the radius; but they are given by observation in minutes and seconds. Now an arc of 1″ may be considered as equal to its sine: hence the arc in seconds is to the arc in parts of the radius as 1″ to sin. 1″; consequently the arc in feet is equal to the arc in seconds × sin. 1″. Multiplying, therefore, by sin. 1″, we get

$$x = \left\{ \left(\frac{\beta+\gamma}{2}\right)^2 \tan. \tfrac{1}{2}a - \left(\frac{\beta-\gamma}{2}\right)^2 \cot. \tfrac{1}{2}a \right\} \sin. 1''$$

Another reduction is necessary. Unless the signals are constructed on purpose, it will rarely happen that the instrument can be placed exactly in the centre of the station.[1] In this case it must be placed at some other point near the centre of the station, and the observed angle reduced to the centre by calculation. Suppose, for example, it were required to determine the angle ACB (fig. 3), which the objects A and B subtend at C, and that the instrument cannot be placed exactly at C. Let P be the point, at a short distance from C, where the instrument is actually placed, and APB be the observed angle; then, since CP can be measured, and CA, CB are supposed to be known, approximately at least, the problem is, having given the angle APB, and the distances CA, CB, and CP, it is required to determine the angle ACB.

Let AC and BP intersect in E. Then, since AEB = ACB + CBP = APB + CAP, we have

$$ACB - APB = CAP - CBP.$$

But $\sin. CAP = \frac{CP}{CA} \sin. CPA$, and likewise $\sin. CBP = \frac{CP}{CB} \sin. CPB$; therefore, making $AC = m$, $BC = n$, $CP = d$, $ACB = C$, $APB = P$, $CPB = p$, then $CPA = P + p$, and by substitution,

$\sin. CAP = \frac{d}{m} \sin. (P+p)$, and $\sin. CBP = \frac{d}{n} \sin. p$, whence, dividing by sin. 1″ to reduce the expression to seconds,

$$CAP = \frac{d}{m} \frac{\sin. (P+p)}{\sin. 1''}, \text{ and } CBP = \frac{d}{n} \frac{\sin. p}{\sin. 1''};$$

therefore (since $CAP - CBP = ACB - APB = C - P$),

$$C - P = \frac{d \sin. (P+p)}{m \sin. 1''} - \frac{d \sin. p}{n \sin. 1''},$$

which gives C, or the angle ACB, expressed in seconds of a degree.

This expression is exact; but an approximation more convenient for calculation, and sufficient in almost every case that can occur in practice, was generally followed by Delambre. Let a circle be described about the triangle ABC, intersecting BP in D, and let CD, DA, and AB be joined. We have then ACB − APB = ADB − APB = DAP. Let the angle CDB (= CAB, which is known by observation) be denoted by A. In the triangle DPA,

$$\sin. DAP = \frac{DP}{AD} \sin. APB = \frac{DP}{AD} \sin. P,$$

and in the triangle DPC,

$$DP = PC \frac{\sin. PCD}{\sin. CDB} = PC \frac{\sin. (CDB - CPB)}{\sin. CDB},$$

$$\text{or } DP = d \frac{\sin. (A-p)}{\sin. A}; \text{ therefore}$$

$$\sin. DAP = \frac{d}{AD} \frac{\sin. (A-p)}{\sin. A} \sin. P.$$

But AD may be considered as equal to AC = m; whence $\sin. DAP = \frac{d \sin. (A-p) \sin. P}{m \sin. A}$, and consequently, when expressed in seconds,

$$DAP = C - P = \frac{d \sin. (A-p) \sin. P}{m \sin. A \sin. 1''}.$$

This expression vanishes when $A - p = 0$, or when the points P and D coincide, that is, when the instrument is placed on the circumference of the circle circumscribing the triangle ACB. And it may be so placed, unless obstacles intervene, by moving it along the line PB, till the angle CDB is observed to be equal to BAC.

When the three observed angles of each triangle have been reduced to the horizon, they represent the angles of a spherical triangle, the sides of which are intercepted by the verticals of the three stations, and the sum of the three angles of each triangle exceeds 180° by a quantity which is called the *spherical excess*. The sides ought therefore to be calculated by the rules of spherical trigonometry; but as the sides of the triangles are in all cases very small in comparison of the radius of the earth, the calculation made in this way (for which indeed the existing tables are not well adapted) becomes exceedingly tedious. Instead, therefore, of calculating directly the spherical triangle, it is more convenient to compute its deviation, which is always very small, from a plane triangle. The method employed by Delambre was the following.

In the first place, the spherical angle, or that which is formed by tangents at the surface, must be reduced to the corresponding plane angle formed by the chords. This is easily accomplished by the help of the theorem above given for reducing the observed angles to the horizon; for the angle formed by the chord and the tangent of an arc is equal to the angle at the centre subtended by half the arc; consequently when the lengths of the two sides of a spherical angle are known nearly, the angle of *depression* of the chords is also known; and therefore the preceding theorem for reducing angles to the horizon can be immediately applied. For example, suppose the sides of a spherical angle to be respectively p and q miles, and the circumference of the earth to be 25,000 miles, then

$$25{,}000 : p :: 360° : \frac{360°\, p}{25{,}000}, \text{ or } \frac{21{,}600''\, p}{25{,}000} = \frac{108\, p}{125} \text{ seconds}$$

of a degree, which is the angle subtended at the centre by the whole arc; and consequently one half of it, or $\frac{54''\, p}{125}$, is the depression of the chord. In the same manner, $\frac{54''\, q}{125}$ is the depression of the chord of q; and by substituting these in the formula

$$x = \left\{ \left(\frac{\beta+\gamma}{2}\right)^2 \tan. \tfrac{1}{2} a - \left(\frac{\beta-\gamma}{2}\right)^2 \cot. \tfrac{1}{2} a \right\} \sin. 1'',$$

we obtain the angles made by the chords, by means of which the triangle may be computed in the same manner as if it were a plane triangle.

To make this reduction, it is necessary to know, approximately at least, the diameter of the earth as well as the distances of the stations; but the result will be little affected by a moderate error in either of these data. In fact, it is only when the sides of the triangles are very large that the effects of the earth's curvature become at all sensible.

But a more elegant manner of estimating the effects of the earth's curvature, though not always of so easy application, was proposed by Legendre. This illustrious geometer discovered the following very remarkable property of spherical triangles; namely, that when the sides are very

[1] This should always be done if possible, and when light signals are used there can rarely be any necessity for a deviation of this kind. (1855.)

small in comparison of the radius of the sphere, if from each of the angles there be subtracted one-third part of the quantity by which the sum of the three angles exceeds two right angles, or 180°, the angles thus diminished may be regarded as the angles of a plane triangle, the sides of which are equal in length to those of the proposed spherical triangle. The excess of the sum of the three angles above two right angles is proved by trigonometry to be equal to $\frac{a}{r^2}$, a being the area of the triangle, and r the radius of the sphere; so that the theorem of Legendre may be enumerated as follows:—

"If the angles of a spherical triangle whose surface is small in comparison of the surface of the whole sphere, be denoted by A, B, and C, and the opposites by a, b, and c, the triangle may be calculated as a plane triangle, the sides of which are a, b, and c, and the opposite angles $A - \frac{1}{3}\epsilon$, $B - \frac{1}{3}\epsilon$, $C - \frac{1}{3}\epsilon$, ϵ being the excess of the sum of the three angles of the proposed spherical triangle above two right angles."

In applying the above theorem, it is necessary first to calculate ϵ or $\frac{a}{r^2}$, which can always be done *a priori* from the known parts of the spherical triangle considered as rectilinear. This being done, we have only to deduct $\frac{1}{3}\epsilon$ from each of the observed angles, and then compute the remaining parts, as in the case of a plane triangle.

By this method, the distances between the several signals may be computed; and as the angles at all the stations are given by observation, the inclinations of all the sides of the triangles to any one of them are also known, so that it is only necessary to determine very accurately the inclination of one side of a triangle to the meridian, in order to ascertain the inclinations of all the other sides, and thence to compute the meridian itself.

The determination of the azimuth of a signal is accomplished by means of astronomical observation, and may be performed in various ways, but all depending on the same principle. It is necessary, however, in any case to be provided with the means of determining the time with very great precision. The azimuth of the sun, or a star, at any given instant, can be determined with sufficient accuracy. Let the observer, therefore, take his station at one of the signals, and observe the angle formed between the other signal and the sun, or a star, when nearly in the horizon, and let him note the instant of time at which the observation was made. Knowing the error of his clock or chronometer, he knows also the true time, and can consequently calculate the azimuth of the observed celestial body. Taking the sum or difference, as the case may be, of this and the observed angle, he obtains the azimuth of the distant signal, or the angle which the straight line joining the two signals makes with the meridian. The refraction will scarcely affect the result; but a small error with respect to the time would lead to considerable errors. If the sun is observed, the error of the clock must be determined by observations of his meridional transits; but most frequently a circumpolar star, as Capella, is preferred. Sometimes the observation is made on the pole star itself; but in this case it is necessary to know the latitude of the station very accurately. Another method is frequently resorted to. Having set up a mark very nearly in the meridian, adjust a transit instrument upon it, and then, by means of the transits of stars at different polar distances, or other means known in practical astronomy, determine the deviation of the instrument from the meridian. This gives the direction of the mark with respect to the meridian, and consequently the angle to be added to or subtracted from the angle between the mark and the signal.[1] For greater security, the azimuths may be observed at several signals. They ought at least to be observed at each extremity of the chain of triangles.

The triangles being calculated and reduced to the horizon, we are now in a condition to compute the length of the arc between the parallels of the extreme stations. Let ABCDEFG, &c. (fig. 4), be a chain of triangles lying nearly in the direction of the meridian AZ, and traced on a spheroidal surface, supposed to be formed by the continuation of the ocean. Let L be the last station, and LX the perpendicular passing through L and meeting AZ in the point X; it is required to determine AX.

By means of the previous calculations, all the sides of the triangles are supposed to have been computed, as well as the azimuth of C, or the inclination of AC to the meridian. Let CD be produced to M. In the triangle ACM there are given the side AC, and the two angles CAM, ACM. To find the third angle AMC, first compute the spherical excess ϵ; from each of the angles CAM, ACM, subtract $\frac{1}{3}\epsilon$; take the sum of the two remainders from 180°, and there will be left the value of AMC. The angles being thus given, and also the side AC, the other two sides AM and CM are computed in the same manner as if the triangle were rectilinear.

In the quadrilateral MDFN there are given the two opposite angles at M and F (the first from the previous calculation, and the second by observation), together with the two sides MD and DF. Draw the diagonal MF; then in the triangle DMF there are given the two sides DM, DF, and the included angle D. From D deduct $\frac{1}{3}\epsilon$, the excess ϵ being computed by an approximate value of the area of the triangle, and compute, as in a plane triangle, the side MF and the two angles DMF, DFM. To each of these add $\frac{1}{3}\epsilon$, and the two sums being deducted from the angles DMN and DFN, there will remain the two angles FMN and MFN. Hence, since MF has been already computed, we can find MN, FN, and the angle MNF, in the usual manner.

Now, in the triangle NPH, NH is known (for FH and FN have been calculated), and the adjacent angles PNH, NHP are given by observation; therefore we can compute NP, PH, and the remaining angle NPH.

To find PX we may produce IL to Z, and resolve the two triangles PIZ and ZLX. In the first of these, the side PI, and the two adjacent angles PIZ, IPZ, are already known; whence we find IZ, PZ, and the angle IZP. We have then in the right-angled triangle LXZ, the side LZ, and the angle LZX to find ZX. From PZ subtract ZX, and there remains PX, the quantity sought.

In proceeding by the method now indicated, the spherical excess ϵ must be first computed for each of the triangles to be resolved; then each observed spherical angle must be diminished by $\frac{1}{3}\epsilon$, in order to allow the calculations to be made by the rules of plane trigonometry; and when the result has been found, we must again add to each angle the small quantity $\frac{1}{3}\epsilon$, in order to have the true spherical angle. (See Delambre, *Methodes Analytiques pour la Determination d'un Arc du Meridien.*)

It is necessary to remark, that the point X, determined by drawing a perpendicular from the last station to the meridian, is not situated exactly on the same parallel of lati-

[1] The most accurate method, being that followed in all the later operations of the Indian survey, is to select a star within a few degrees of the pole, and observe its angular deviation from a fixed mark at both elongations E. and W. of the meridian. The mean of these two angles will give the true azimuth of the mark free from any error in the place of the star; as the star moves slowly in azimuth when near its elongation, a small error in the time is also of no consequence. The star should be selected so as to arrive at its elongations not far from sunrise and sunset, and several observations may be made at each elongation. (1855.)

tude with L. Its latitude is a little greater than that of L; and unless the distance of the station from the meridian is very small, the difference will be sensible, and requires to be calculated. Conceive another point, L′ (fig. 5), on the same parallel of latitude with L, and at the same distance from the meridian on the opposite side. The point X is on the circumference of a great circle, perpendicular to the meridian PE, and passing through L and L′; but the small circle, or parallel of latitude of L and L′, intersects the meridian in a different point l. Now let PE (fig. 6) be the meridian, XC the intersection of its plane with that of the great circle passing through the points LL′, and ln the intersection of the plane of the meridian and the plane of the small circle or parallel of latitude passing through the same points LL′, so that El is the latitude of L, EX that of the point X, and lX the distance between the perpendicular and the small circle passing through L. Let ln and XC intersect in m, then lX being a small arc, may be regarded as a straight line; consequently $\mathrm{X}l = m\mathrm{X} \tan. \mathrm{X}ml$. But $\mathrm{X}ml = \mathrm{XCE}$ = latitude of L very nearly, consequently, taking λ to denote the latitude of L, we have $\mathrm{X}l = m\mathrm{X} \tan. \lambda$. Now mX is the versed sine of the arc whose chord is LX; therefore, making d=earth's diameter, $m\mathrm{X} = \frac{\mathrm{LX}^2}{d}$, and consequently $\mathrm{X}l = \frac{\mathrm{LX}^2}{d} \tan. \lambda$, which is the quantity to be subtracted from the calculated meridional arc.

Delambre employed a different method of computing the distance between the parallels of the terminal points of the measured arc. It requires, however, the dimensions of the earth to be previously known with tolerable accuracy. Let AB (fig. 7) be the arc measured on the surface of the spheroid PAB; then, having observed the latitude of the station A, and the azimuth of AB, that is the angle BAP, we have sufficient data, supposing the dimensions of the earth to be nearly known, to find not only the distance between the parallels of A and B, but also the latitude and longitude of B, and the azimuth of BA, as observed from B. Through A and B draw the normals AM and BN, meeting the axis in M and N; join BM, AN; and about M as a centre, with an arbitrary radius, describe the circular arcs bp, pa, ab, forming the spherical triangle pab. Now, if we compare the triangle PAB on the spheroid with pab on the sphere, we find pa=PA in degrees, each being the colatitude of A; pb=PB, each being the colatitude of B; the angle apb =APB being the difference of longitude of A and B, and also the angle pab=PAB, each measuring the inclination of the planes PMA, AMB. But the angle pba is in general not equal to PBA; for as the normals do not meet the axis in the same point, the planes AMB and ANB do not coincide; and pba is the measure of the inclination of PMB and AMB, whereas PBA is the measure of the inclination of PMB and ANB. Now, in the triangle pba there are given the angles at p and a, so that if the side ab can be determined in terms of AB, the other parts of the triangle may be computed, and thence the difference between pb and pa, or the distance between the parallels, which being found in terms of BA, will be expressed in feet.

We have therefore to find an expression for ab, or the angle AMB. Now, in the triangle ABM there are given AB (the measured arc), and AM the normal at A (the dimensions of the earth being nearly known). But $\mathrm{BM} = \mathrm{BN} \frac{\sin. \mathrm{MNB}}{\sin. \mathrm{NMB}}$; and if we make l = PNB the colatitude of B, and x = NBM, we shall have NMB = PNB $- x = 90° - l - x$; therefore sin. NMB = cos. $(l + x)$; we have also sin. MNB = sin. $(90° - l)$ = cos. l; wherefore $\mathrm{BM} = \mathrm{BN} \frac{\cos. l}{\cos. (l+x)} =$

$$\mathrm{BN} \frac{\cos. l}{\cos. l \cos. x - \sin. l \sin. x} = \mathrm{BN} \frac{1}{\cos. x - \tan. l \sin. x}$$

$$= \mathrm{BN}\ (1 + \tan. l \sin. x + 2 \sin.^2 \frac{x}{2} +, \&c.$$

Now x is a very small angle; its sine is in fact expressed in terms of the square of the excentricity, so that terms multiplied by it may be neglected without any sensible error. We may therefore assume BM=BN. In the triangle ABM we have then given the three sides, whence the angles may be computed, and consequently ab=AMB becomes known.

Having found ab, we have given in the triangle abp the two sides pa, ab, and the observed angle pab, from which to compute the remaining parts of the triangle, viz. pb the latitude of B, apb its longitude, and pba the azimuth of A, as seen from B. Make $pa' = pa$, and Pb' to PB, then $ba' = pb - pa$ is the distance between the parallels, the radius being unit; therefore, since 1 : MA :: $a'b$: Ab', we have $\mathrm{A}b' = \mathrm{AM} \times a'b$, that is, the distance between the parallels of the extreme stations on the spheroid.

When the distance between the parallels of the extreme points of the arc has been ascertained, it only remains to determine the difference of their latitudes, or the length of the corresponding celestial arc. This is the most difficult part of the whole operation. The error of a single second in the difference of the latitudes corresponds to about a hundred feet on the terrestrial meridian; and when it is considered that the latitudes of the best determined spots on the earth, even of the Observatories of Greenwich and Paris are still uncertain to the amount of at least half a second, it will be easily apprehended that the errors of the latitudes are more to be feared than any which can affect the measurement of the base, or the angles, or the direction of the meridian. In the British survey, that of India, and some on the Continent, the latitudes were observed with the zenith sector, an instrument peculiarly adapted to this purpose. Ramsden's zenith sector, made expressly for the determination of the arc of meridian between Dunnose and Clifton, carried a telescope of eight feet in length. With this superb instrument, for a description of which we must refer to the second volume of the *Trigonometrical Survey*, the zenith distances of several of the northern stars were observed at both extremities of the arc; and the difference of two zenith distances of the same star is evidently the same as the difference of the latitudes of the two stations. It may be remarked, that the result of this observation is independent of the declination of the star; and if the observation is made at the second station within a short time after it was made at the first, the result is also nearly independent of the nutation.[1]

For the determination of the French arc of meridian, the latitudes were observed with the repeating circle. This instrument, on account of its portability, is of the greatest use in geodetic operations; but it may be questioned whether it can be safely relied on for the determination of so very important an element as the latitude. Besides the want of power in the telescope, it is found to be affected in some unaccountable way by a constant error, which, however carefully its amount may have been determined, leaves a degree of uncertainty with regard to the results. Mechain mistook the latitude of Barcelona by about 3″. It is to be regretted that the latitudes of Dunkirk and Formentera, the extremities of the French arc,

[1] The latitudes of the later portions of the Indian meridional arc were measured by simultaneous observations at each extremity of the same stars, with 3-feet altitude and azimuth circles; a method every way preferable to that with the sector. (1855.)

have not been determined with the zenith sector. All the other operations connected with the measurement of that extensive arc have been executed in a style of such decided superiority, that a more satisfactory, if not more accurate, determination of the latitudes is alone wanting to render it the most valuable application of science that has ever been made with a view to ascertain the magnitude and exact figure of our globe.

The measurement of an arc of parallel usually forms part of the operations connected with the survey of a large extent of country. It will frequently happen that the sides of some of the great triangles lie in a direction nearly perpendicular to the meridian, in which case the arc of the terrestrial parallel may be easily computed from an approximate knowledge of the earth's dimensions; and if the difference of longitude of the two stations, or the angle which their respective meridians make with each other, has been accurately determined, the comparison of the corresponding celestial and terrestrial arcs will give the length of the degree on the parallel. By comparing this result with the length of a degree measured on a different parallel, or on the meridian, we can easily deduce the ellipticity.

Perhaps the simplest way of conveying an accurate idea of the nature of the operations necessary to be undertaken in the measurement of an arc of parallel, will be to describe the method that was actually followed in the British trigonometrical survey, in determining the length of an arc of parallel from the measured distance between Beachy Head and Dunnose.

Let BW (fig. 8) be an arc of the great circle perpendicular to the meridian of Beachy Head at B, meeting that of Dunnose in W; and let DR be an arc of the great circle perpendicular to the meridian of Dunnose at D, meeting that of Beachy Head in R; and let BL and DE be the parallels of latitude passing through B and D. It is supposed that the latitudes of the two places have been determined, together with the angles PBD and PDB, which they reciprocally make with each other and the pole; and also that the distance between them on the arc of the great circle has been measured: the question is then to find the difference of their longitudes, or the angle BPD, and the distance in feet between the meridians on the arcs of the small circles BL and DE passing through the places.

In the small spheroidal triangle WBD there were given by observation the two angles WBD and WDB, which being reduced to the angles made by the chords, gave the two angles of the corresponding plane triangle. The side BD was found by triangulation = 339,397·6 feet; whence the chord of the perpendicular arc BW was found = 336,115·6 feet. In like manner the chord of DR was found = 336,980 feet.

The terrestrial distances being thus found, it was next necessary to find the difference of longitude, or the angle P, and the lengths of the arcs of parallel BL and DE in degrees. For this purpose there are given PB the colatitude of B, PD the colatitude of D, the angle PBD, which is the azimuth of D as seen from B, and PDB the azimuth of B as seen from D.

The rigorous solution of this problem on the spheroid is attended with considerable difficulty. An approximation is however easily obtained from a property of spheroidal triangles (for the demonstration of which we must refer to the *Phil. Trans.* vol. lxxx.), namely, that the sum of the horizontal angles on a spheroid (or indeed on any surface differing little from that of a sphere) is *nearly* the same as the sum of those which would be observed on a sphere, the latitudes and difference of longitudes being the same on both figures. Assuming therefore the sum of the two angles PDB and PBD to be the same as the sum of two spherical angles, we have, from Napier's analogies (see TRIGONOMETRY),

$$\cos.\tfrac{1}{2}(PD+PB):\cos.\tfrac{1}{2}(PD-PB) = \cot.\tfrac{1}{2}P:\tan.\tfrac{1}{2}(PDB+PBD),$$

whence

$$\tan.\tfrac{1}{2}P=\frac{\cos.\frac{1}{2}(PD-PB)}{\cos.\frac{1}{2}(PD+PB)}\times\cot.\tfrac{1}{2}(PDB+PBD);$$

that is to say, the tangent of half the difference of longitudes is equal to the cotangent of half the sum of the azimuthal angles multiplied into the ratio of the cosine of half the difference of the colatitudes to the cosine of half their sum. In the case under consideration the angle P was found = 1° 26′ 47″·93.

We have now given, in the right-angled triangle PBW, which may be considered as spherical, the side PB and the angle P, whence BW was found = 54′ 56″·21. And from the triangle PDR, in which the side PD and the angle P are given, DR was found = 55′ 4″·74.

The chords of the two perpendicular arcs BW and DR, whose radius is the radius of the earth, are found, from an approximate knowledge of the earth's diameter, to be three feet and a half shorter than the arcs themselves, whence the arc BW = 336,119·1 feet, and DR = 336,983·5 feet. Hence the length of the degree of the great circle perpendicular to the meridian, at the middle point between W and B, is found by proportion = 367,096·8 feet, and in the middle point between R and D = 367,090·8 feet. Therefore the mean, or 367,093·8, is the length of a degree of the great circle perpendicular to the meridian in latitude 50° 41′, which is nearly that of the middle point between Beachy Head and Dunnose.

Now, by reason of the short distance between the two stations, and their small difference in latitude, the two radii of curvature at B and D may be regarded as intersecting each other on the axis at M (fig. 9). Therefore DM is the radius of the great circle perpendicular to the meridian, and DE is the radius of the parallel at D. Therefore 1° of the great circle : 1° of the parallel as DM : DE; and DM : DE = 1 : cos. latitude of D; whence 1 : cos. 50° 44′ 24″ = 367,094 : 232,314 feet for the degree of parallel at Beachy Head, and 1 : cos. 50° 37′ 7″ = 367,094 : 232,914 feet for the degree of parallel at Dunnose. (*Trig. Survey,* vol. i. p. 113.)

The length of the degree of the great circle perpendicular to the meridian, deduced in the manner now explained, is about 1250 feet greater than on the spheroid which corresponds with the measurements of the meridional arcs. This discrepancy gave rise to a suspicion of errors in the observation of the azimuthal angles; and, in fact, the difference of longitude, in order to agree with other determinations, ought to be about 18″ greater than that which was determined in the survey. With this correction the length of the degree of the perpendicular circle is found = 365,838 feet. Assuming the dimensions of the earth deduced from the survey, the length of the degree perpendicular to the meridian at the mean latitude is 365,844 feet. Hence 1° parallel = 231,801 feet.

In the *Philosophical Transactions* for 1824 an account is given of some experiments performed by Dr Tiarks for determining the difference of longitude of Dover and Falmouth. Twenty-four chronometers were transported by sea, three several times, from the one place to the other, by which means the difference of the apparent times was determined. The difference of longitude was thus found to be 6° 22′ 6″; and the length of the parallel, as found from the survey, being 1,474,672 feet, we have the length of a degree of parallel at latitude 50° 44′ 24″ = 231,563 feet.

The most extensive arc of parallel which has yet been

measured is that between Marennes (near Bordeaux) and Padua. The details of the operations, which were performed in 1822 and 1823, are given in the *Connaissance de Tems* for 1829. The terrestrial arc was determined by triangulation in the usual manner, and the astronomical amplitude by fire signals observed from station to station at five intermediate stations. There are consequently six independent arcs; and the final result is affected with the accumulated errors at all the stations. The terrestrial distance was found to be 1,010,996 mètres, or 3,316,976 English feet; and the difference of time determined by chronometers 51 min. 56·24 sec., corresponding to 12° 59′ 3″·75 of longitude. The mean length of the degree, found from the partial arc between Marennes and Geneva, is 255,546 feet, and from the whole arc between Marennes and Padua 255,470 feet, both of which results are greater than the degree on the regular spheroid, which is found to represent most nearly the meridional arcs under the same parallel of latitude, namely, 45° 43′ 12″. A better example has been afforded by the measurement in 1845 of the arc of parallel between Greenwich and Valentia (Ireland) by the Astronomer Royal; while the instantaneous transmission of time signals by the electric telegraph, which has arisen even since that late date, is (1855) being employed by many astronomers in Europe and America for supplying still better materials for new arcs of *parallel*, and making them indeed of as much scientific importance as arcs of the *meridian*.

SECTION III.

DETERMINATION OF THE FIGURE OF THE EARTH FROM GEODETIC MEASURES.

Assuming the figure of the earth to be that of an elliptic spheroid of revolution, the magnitude and ratio of its equatorial and polar diameters may be determined from the comparison of the lengths of lines measured between determined points on its surface, with the corresponding arcs of the celestial sphere, by means of theorems which we shall now proceed to demonstrate.

1. *To express the radius of curvature of a meridian in terms of the latitude.*

Let PDQ (fig. 10) be the meridian, CP half the polar axis, CQ the radius of the equator, DM a perpendicular to the tangent at D, meeting CP in M, and CQ in N; and let

a = CP half the polar axis,
b = CQ the radius of the equator,
n = DN the normal at D,
r = radius of curvature at D.

Join CD; let CD′ be the diameter conjugate to CD, meeting DM in G; and through D draw DE and DF respectively perpendicular to CP and CQ. It is demonstrated in the article Conic Sections (Part IV. Sec. 2, Prop. V. Cor. I.), that $r \times \mathrm{DG} = \mathrm{CD}'^2$; and (Prop. XVII. Part II.) $\mathrm{CD}' \times \mathrm{DG} = \mathrm{CP} \times \mathrm{CQ} = ab$; whence $\mathrm{CD}'^2 = a^2 b^2 \div \mathrm{DG}^2$; and consequently $r \times \mathrm{DG}^3 = a^2 b^2$. But (Prop. XXI. Part II.) $\mathrm{DN} \times \mathrm{DG} = \mathrm{CP}^2$; that is, $n \times \mathrm{DG} = a^2$; whence $n^3 \times \mathrm{DG}^3 = a^6$, and therefore $\mathrm{DG}^3 = a^6 \div n^3$, consequently

$$r = \frac{b^2 n^3}{a^4} \quad \text{(1.)}$$

Again (Prop. XXI. Part II.) $\mathrm{DN} : \mathrm{DM} = a^2 : b^2$; and the triangles NCM, NFD being similar, DN : DM = NF : CF, whence $\mathrm{CF} = \frac{b^2}{a^2}\mathrm{NF}$. Now let the angle DNF or the latitude of D $= l$; then DF $= n \sin. l$, NF $= n \cos. l$, and CF $= \frac{b^2}{a^2} n \cos. l$. But DF = CE $= x$ and CF $= y$; substituting therefore $n \sin. l$ for x, and $\frac{b^2}{a^2} n \cos. l$ for y in the equation of the ellipse, namely,

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1,$$

we find

$$\frac{n^2 \sin.^2 l}{a^2} + \frac{b^2 n^2 \cos.^2 l}{a^4} = 1,$$

whence

$$n^2 = \frac{a^4}{a^2 \sin.^2 l + b^2 \cos.^2 l}.$$

Let $b = a(1 + e)$ (e denoting the ellipticity or the ratio of the difference of the semiaxes to the polar semiaxis, that is, $e = \frac{b - a}{a}$; by substituting, we get

$$n^2 = \frac{a^2}{\sin.^2 l + (1 + e)^2 \cos.^2 l};$$

but since the ellipticity e is very small, all terms multiplied by the square or higher powers of e may be rejected without sensible error. Hence $(1 + e)^2 = 1 + 2e$, and therefore $n^2 = \frac{a^2}{1 + 2e \cos.^2 l}$, or $n = a(1 + 2e \cos.^2 l)^{-\frac{1}{2}}$;

whence, on developing and rejecting terms containing e^2,

$$n = a(1 - e \cos.^2 l) \quad \text{(2.)}$$

Now, from equation (1), $r = \frac{b^2}{a^4} n^3 = \frac{1 + 2e}{a^2} n^3$; and from equation (2), $n^3 = a^3(1 - 3e \cos.^2 l)$; therefore $r = a(1 + 2e)(1 - 3e \cos.^2 l) = a(1 + 2e - 3e \cos.^2 l)$; or, finally,

$$r = a(1 - e + 3e \sin.^2 l) \quad \text{(3.)}$$

2. *To express the radius of a circle parallel to the equator in terms of the latitude.*

Suppose the parallel to pass through D, then DE $= y$ is the radius required. But it was shown in the last Prop. that CF (= DE) $= \frac{b^2}{a^2} n \cos. l$; therefore, substituting $a^2(1 + 2e)$ for b^2, we have $y = n \cos. l (1 + 2e)$. Substituting in this the value of n given by equation (2), we have $y = a \cos. l (1 + 2e)(1 - e \cos.^2 l)$; whence $y = a \cos. l (1 + 2e - e \cos.^2 l)$, or

$$y = a \cos. l (1 + e + e \sin.^2 l) \quad \text{(4.)}$$

3. *To find an expression for the length of an arc of the meridian, in terms of the latitudes of its extreme points.*

If the arc is small, it may be regarded as coinciding with the osculating circle at its middle point. Let z = the arc, and r = the radius of curvature at its middle point; then (z being supposed small) we have $z = r \sin. z$. But $z : \sin. z = 1'' : \sin. 1''$; therefore $\sin. z = z \sin. 1''$, and the length of the arc in feet $= r z \sin. 1''$. Now let l and l' be the latitudes at the extremities of the arc, then $\frac{1}{2}(l + l')$ is the latitude of its middle point; and on substituting for r its value found in equation (3), the expression for the length of a meridional arc, in terms of its extreme latitudes l' and l, is

$$z = a\left\{1 - e + 3e \sin.^2 \tfrac{1}{2}(l + l')\right\}(l' - l) \sin. 1'' \quad \text{(5.)}$$

But if the arc is of considerable extent, this expression will not be sufficiently exact, and it becomes necessary to find by integration the lengths of the arcs from the equator to each extremity of the given arc: the difference of these two will give z itself. At the latitude l, $dz = r dl$; therefore, from equation (3),

$$dz = a(1 - e)\,dl + 3ae \sin.^2 l\,dl,$$

and integrating,

$$z = al - ael + 3\,ae\int \sin.^2 l\, dl.$$

But $\int \sin.^2 l dl = \frac{1}{2} l - \frac{1}{4} \sin. 2\,l$; therefore

$$z = a\left\{ (1 + \tfrac{1}{2} e)\, l - \tfrac{3}{4} e \sin. 2\,l \right\} \ldots\ldots\ldots\ldots\ldots (6.)$$

No constant is necessary, because at the equator z and l vanish together.

Let z' be another arc reckoned from the equator to the point whose latitude is l'; then, similarly,

$$z' = a\left\{ (1 + \tfrac{1}{2} e)\, l' - \tfrac{3}{4} e \sin. 2\,l' \right\};$$

and consequently

$$z' - z = a\left\{ (1 + \tfrac{1}{2} e)(l' - l) - \tfrac{3}{4} e (\sin. 2\,l' - \sin. 2\,l) \right\};$$

but $\sin. 2\,l' - \sin. 2\,l = 2 \cos. (l' + l) \sin. (l' - l)$; therefore

$$z' - z = a\left\{ (1 + \tfrac{1}{2} e)(l' - l) - \tfrac{3}{2} e \cos. (l' + l) \sin. (l' - l) \right\},$$

or, as $l' - l$ is expressed in seconds, $z' - z$

$$= a\left\{ (1 + \tfrac{1}{2} e)(l' - l) \sin. 1'' - \tfrac{3}{2} e \cos. (l' + l) \sin. (l' - l) \right\} (7.)$$

4. *To express the length of an arc of parallel in terms of the radius.*

Let $y =$ the radius, D $=$ the amplitude of the arc in seconds, and V $=$ its length in feet. Then, by what is shown above, the length of the arc in feet is yD sin. 1″. Hence, from the value of y given in equation (4), the length of the arc of parallel at latitude l is

$$V = a \cos. l\, (1 + e + e \sin.^2 l)\, D \sin. 1'' \ldots\ldots\ldots (8.)$$

5. *From the measured length of two degrees of meridian at different latitudes, to determine the axis and ellipticity of the spheroid.*

Let Z and Z′ be the measured lengths of two degrees, and the latitudes of their middle points be respectively L and L′; then (since in this case $l' - l = 1° = 3600''$) we have, by equation (5),

$$Z = a\,(1 - e + 3\,e \sin.^2 L)\, 3600 \sin. 1'',$$

$$Z' = a\,(1 - e + 3\,e \sin.^2 L')\, 3600 \sin. 1'',$$

therefore

$$\frac{Z'}{Z} = \frac{1 - e + 3\,e \sin.^2 L'}{1 - e + 3\,e \sin.^2 L};$$

whence, performing the division, and neglecting terms multiplied by e^2,

$$\frac{Z'}{Z} = 1 + 3\,e\,(\sin.^2 L' - \sin.^2 L),$$

from which we find the ellipticity.

$$e = \frac{Z' - Z}{3\,Z\,(\sin.^2 L' - \sin.^2 L)} \ldots\ldots\ldots\ldots\ldots\ldots (9.)$$

The accuracy of this expression will depend on the magnitude of the denominator, or the difference between L′ and L. If L is nearly equal to L′, the denominator becomes very small, and the value of e in consequence uncertain. The most favourable determination, therefore, that can be obtained is, when one of the degrees, Z′, for example, is measured near the pole, and Z at the equator, where L is zero. As an example of this method, we may deduce the value of e from a comparison of the lengths of a degree at the equator and in England. Bouguer found the length of the degree at the equator to be 362,932 English feet; and from the British arc, between Dunnose and Clifton, the length of the degree is 364,970 feet, at the latitude of 52° 35′ 45″. We have therefore Z $=$ 362,932, Z′ $=$ 364,970, L $=$ 0, L′ $=$ 52° 35′ 45″, by substituting which in equation (9), there results

$$e = \frac{2038}{3 \times 362932 \times \sin.^2 (52°\, 35'\, 45'')},$$

whence $e = \dfrac{1}{346}$.

Having found the value of e, that of the polar semi-diameter, or a, is obtained as follows. At the equator, where L vanishes, we have $Z = a (1 - e)\, 3600 \sin.''$, whence

$$a = \frac{Z}{(1 - e)\, 3600 \sin. 1''} = \frac{Z \times 346}{345 \times 3600 \sin.''};$$

and substituting 362,932 for Z, we find

$$a = 20{,}855{,}000 \text{ feet nearly.}$$

The method of deducing the ellipticity and dimensions of the earth which has now been explained, may be conveniently employed when the measured arcs are small; but when the arcs are considerable (and it is necessary that they should extend over several degrees, in order to give results deserving of confidence), we must employ the more accurate expression of the arc found in equation (7); that is to say, we must employ the whole arc measured, instead of the resulting length of a single degree. Equation (7), when reduced to numbers, takes the form

$$A = am + aen \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (10.)$$

in which m, n, and the arc A, are numbers determined by observation. Another arc will give a similar equation,

$$A' = am' + aen',$$

and by combining the two equations we get

$$e = \frac{Am' - A'm}{A'n - An'};\quad a = \frac{An' - A'n}{mn' - m'n} \ldots\ldots\ldots\ldots\ldots\ldots (11.)$$

If the terrestrial meridian were a regular ellipse, the ellipticity deduced from two measured arcs would be the same at every latitude. But it is found that no two different measures that have yet been effected concur in giving exactly the same figure to the meridian. Hence it becomes necessary to seek the most probable mean among the different results. Each new measure affords a new equation of condition, of the form of equation (10); and as the number of unknown quantities remains the same, whatever may be the number of equations, recourse must be had to the method of least squares, or some of the other methods of combination employed by astronomers. In this way each individual measurement serves to correct the results given by the former ones.

6. *From the measured lengths of an arc of meridian, and an arc of parallel, to determine the ellipticity of the spheroid.*

Let z be the arc of meridian between the latitudes l and l', V the length of the arc of parallel in feet at the latitude L, and D the difference of longitude in seconds between its extreme points. From equation (5) we have

$$z = a\left\{ 1 - e + 3\,e \sin.^2 \tfrac{1}{2}(l' + l) \right\} (l' - l) \sin. 1'',$$

and from equation (8),

$$V = a\,(1 + e + e \sin.^2 L) \cos. L \times D \sin. 1'',$$

whence

$$\frac{V}{\cos. L \times D \sin. 1''} - \frac{z}{(l' - l) \sin. 1''}$$

$$= ae\left\{ 2 + \sin.^2 L - 3 \sin.^2 \tfrac{1}{2}(l' + l) \right\},$$

and, consequently,

$$e = \frac{\dfrac{V}{\cos. L \times D \sin. 1''} - \dfrac{z}{(l' - l) \sin. 1''}}{a\left\{ 2 + \sin.^2 L - 3 \sin.^2 \tfrac{1}{2}(l' + l) \right\}} \ldots\ldots\ldots\ldots (12.)$$

When the two arcs have been measured at the same

latitude, that is, when $L = \frac{1}{2}(l' + l)$, the denominator of this fraction becomes $a\,(2 - 2\sin.^2 L) = 2\,a\cos.^2 L$. This combination may be considered as giving a correct representation of the curvature at any particular place, or of the dimensions and eccentricity of the osculating spheroid at that place. But, speaking generally, the exact determination of the differences of longitude is attended with so much uncertainty, that the results obtained from the comparison of arcs of parallel, either with one another or with arcs of meridian, cannot be relied on with much confidence. It is consequently unnecessary to point out the equations to be employed in deducing the ellipticity from the comparison of two arcs of parallel.

We shall now proceed to apply the above formulas to the results of the principal geodetic measurements that have been executed in different countries. The following table contains twenty arcs of meridian, between the equator and 66° of north latitude; and as they have all been determined with the utmost attention to every circumstance which could be supposed to affect their accuracy, they may be regarded as decidedly the best elements we yet possess for the solution of the problem of the figure of the earth. We have excluded all the ancient arcs except that of Bouguer, and also some recent ones, where the locality was unfavourable. They are all reduced to the level of the sea. In reducing the foreign measures, the metre has been assumed (according to Captain Kater's determination) = 3·280899 feet, and the toise = 6·394596 feet, of Schuckburgh's scale. The original documents are given in the various works to which reference has been made in the first section of this article.

* On remeasurement by Colonel Everest, the arc from Damergidda to Kalianpoor was found to embrace an amplitude of 6° 3′ 55″·97, and a length of 2202926·2 feet. (1855.)

Substituting in equation (7) the values of $z'-z$, l, and l', for each of the arcs in the above table, we obtain the following equations of condition:

1. $a \times \cdot 0544111 - ae \times \cdot 05426 = 1131057$
2. $a \times \cdot 0276169 - ae \times \cdot 02371 = 574368$
3. $a \times \cdot 0495037 - ae \times \cdot 04536 = 1029171$
4. $a \times \cdot 0716119 - ae \times \cdot 06058 = 1489198$
5. $a \times \cdot 0515924 - ae \times \cdot 03891 = 1073409$
6. $a \times \cdot 0531157 - ae \times \cdot 03519 = 1105499$
7. $a \times \cdot 0527472 - ae \times \cdot 02933 = 1097320$
8. $a \times \cdot 0470778 + ae \times \cdot 01131 = 982247$
9. $a \times \cdot 0323260 + ae \times \cdot 01159 = 674623$
10. $a \times \cdot 0517210 + ae \times \cdot 02504 = 1079706$
11. $a \times \cdot 0465751 + ae \times \cdot 02940 = 973853$
12. $a \times \cdot 0381990 + ae \times \cdot 02893 = 798971$
13. $a \times \cdot 0077158 + ae \times \cdot 00636 = 161412$
14. $a \times \cdot 0280221 + ae \times \cdot 02335 = 586319$
15. $a \times \cdot 0215422 + ae \times \cdot 01900 = 450018$
16. $a \times \cdot 0194397 + ae \times \cdot 01875 = 406516$
17. $a \times \cdot 0351849 + ae \times \cdot 03132 = 736426$
18. $a \times \cdot 0327868 + ae \times \cdot 03708 = 686022$
19. $a \times \cdot 0297797 + ae \times \cdot 03618 = 623719$
20. $a \times \cdot 0283097 + ae \times \cdot 04293 = 593278$

From any two of these equations we may deduce values of a and e; but, as might be expected, the results are found to be very different according as different arcs are selected for comparison. We may also add any number of the equations together, for instance Nos. 3, 4, 5, 6, and 7, the sum of which forms the continuous arc measured in India by Colonel Lambton and Captain Everest: or Nos. 8, 9, 10, 11, and 12, which form the French arc from Dunkirk to Formentera. But as it is impossible to satisfy at once all the equations by any value whatever that can be assigned to a and e, in order to exclude all arbitrary hypotheses, it is necessary to suppose all the observations to have been alike good, and deduce values of a and e from a combination of the whole. The best method of effecting the combination is that of *minimum squares*, the principle of which is contained in the following rule: Multiply all the terms of each of the proposed equations by the co-efficient of a in that equation, taken with its proper sign, and make the sum of all the products equal to zero. This will give an equation in which the sum of the squares of the errors is a minimum in respect of a. Multiply then each equation by the co-efficient of ae in that equation, and make the sum of all the products $= 0$. This will give a second equation, in which the sum of the squares of the errors is a minimum in respect of ae. From the two equations thus obtained, the values of a and ae, and consequently e, are found in the usual manner. The operation is extremely laborious when the equations are numerous, but it is attended with no difficulty.

By combining the above twenty equations in the manner now described, M. Schmidt obtained the following results, which are given in No. 213 of Schumacher's *Astronomische Nachrichten*, p. 371; and they are unquestionably entitled to be regarded as the best determination of the magnitude and figure of the earth which has been found from the operations that have been undertaken up to the present time for the measurement of meridional arcs.

Radius of equator $= b = 20921665$ Eng. feet.

Radius of pole..... $= a = 20852394$

$$\text{Ellipticity} = e = \frac{b-a}{a} = \frac{1}{301\cdot 02} = \cdot 0032555$$

Degree at equator...... $= 362732$

Degree at latitude 45° $= 364543\cdot 5$

In order to discover how nearly the different measures agree with a spheroid having the dimensions now given, we shall compare the length of a degree, as given by each of the above twenty arcs, with its length, computed from these values of a and e at the same latitudes.

No.	Latitude of Middle Point.	Measured Length of Degree.	Computed Length of Degree.	Error in Measure.

20	66 20 11	365,697	365,777	— 80

From this table we see that the degrees increase gradually from the equator to the pole; but the increase is by no means regular. It occurs in some instances that the degrees appear to diminish on going northward; but these anomalies must be ascribed either to errors in the observations or to local irregularity of form or density. The most probable source of error is in the latitudes, first, on account of the difficulty of the observation to the requisite degree of accuracy; and, secondly, on account of the irregularities in the density of the exterior crust of the earth, which cause a deflexion of the plumb-line from the true zenith. Hence the longest arcs are the best; for the probable error in the determination of the difference of latitudes is the same whether the arcs are great or small. An error of 1″ in the latitude corresponds to about a hundred feet on the ground.

If we compare the degree found by some of the measures which have been rejected from the foregoing table, with the degree computed for the same latitudes, we shall find the errors or anomalies much greater.

Arcs.	Lat. of Middle Point.	Measured Length of Degree.	Computed Length of Degree.	Difference.
Lacaille's arc at Cape of Good Hope	—33° 18′ 30″	364,712	363,826	+ 886
North American arc, by Mason and Dixon	39 12 00	363,786	364,181	— 395
Roman arc, by Boscovich	42 59 00	364,262	364,418	— 156
Piedmontese arc, by Plana and Carlini	44 57 30	368,242	364,543	+ 3699
Maupertuis' Swedish arc	66 19 37	367,086	365,774	+ 1312

Figure of the Earth.

Two of these differences are considerably greater than any in the preceding table. Lacaille's arc corresponds to one in the northern hemisphere at a higher latitude by 14°, whence it has been inferred that the two hemispheres are not exactly similar. The measurement of Plana and Carlini appears to have been excellent; but both extremities of the arc were in the immediate vicinity of lofty mountain ranges, and the very great deviation from the mean result of the other measures can only be accounted for by the disturbing effects of local attraction. Maupertuis' arc was never reckoned of much value, as it was evident from the first that there was an error in the determination of the latitudes.

Taking the results of the four arcs of parallel mentioned before, and computing the corresponding degree from the formula $a \cos. l\,(1 + e + e \sin.^2 l)\ 3600 \sin. 1''$ (supposing a and e to have the same values as above), we get the following table:

Arcs of Parallel.	Latitude.	Measured Degree.	Computed Degree.	Difference.
Lacaille's arc across the mouth of the Rhone..............	43° 31′ 50″	266,345	265,154	+ 1191
Roy's arc from Beachy Head to Dunnose....................	50 44 24	232,331	231,542	+ 789
Arc from Dover to Falmouth......................................	50 44 24	231,579	231,542	+ 37
Arc from Padua to Marennes....................................	45 43 12	255,480	255,370	+ 110

It is remarkable that all these errors are affected with the same sign; and the circumstance might seem to strengthen a conclusion indicated by a comparison of the errors of the meridional arcs, namely, that the meridional curve is not exactly an ellipse, but protuberant between the latitudes of 40° and 52°; in consequence of which the degrees of meridian are shorter, and the degrees of parallel longer between those latitudes, than if the earth were a regular ellipsoid. There is no reason to infer that the meridians are not similar, or that the earth is not a solid of revolution.

The six partial arcs into which the whole arc from Marennes to Padua was divided, give the following results (*Connaissance des Tems*, 1829).

	Arcs.	Astronomical Amplitudes. h. m. sec.	Length in Feet.	Length of Degree.
1	Marennes to St Preuil..	0 3 48·99	244,123	255,865
2	St Preuil to Sauvagnac..	0 6 23·09	407,429	255,248
3	Sauvagnac to Isson...	0 6 51·39	437,493	255,228
4	Isson to Geneva..	0 11 57·82	764,736	255,686
5	Geneva to Milan..	0 12 9·57	776,646	255,486
6	Milan to Padua..	0 10 45·38	686,549	255,308

The mean of these results, or the most probable value of the degree of parallel at the latitude of the stations (45° 43′ 12″), is 255,470 feet, exceeding the computed length only by a hundred feet; and the ellipticity which they indicate is $\frac{1}{282\cdot8}$. This is considerably greater than the ellipticity indicated by the measures of meridional arcs, but agrees pretty nearly with that which we shall see is given by the pendulum observations. The results, however, though valuable as confirming the results obtained by other methods, are not by any means worthy of the same confidence as those deduced from the measurement of meridional arcs.

We shall conclude this section with a re-statement of the dimensions of the earth, resulting from the principal measures of arcs of meridian.

		Feet.		Miles.
Equatorial diameter.............	=	41843330	=	7924·873
Polar diameter.....................	=	41704788	=	7898·634
Difference of diameters, or polar compression...........	=	138542	=	26·239
Ratio of diameters...............	=	302·026	:	301·026

$$\text{Ellipticity} = \frac{b-a}{a} = \frac{1}{301\cdot026}$$

Length of degree at equator = 362732 feet.
Length of degree at lat. 45° = 364543·5 feet.

SECTION IV.

THEORETICAL INVESTIGATION OF THE FIGURE OF THE EARTH FROM THE LAWS OF HYDROSTATICS.

In attempting to deduce the figure of the earth from the general laws of hydrostatic equilibrium, we suppose the whole mass to have been originally fluid, or in such a state, that all its molecules were at liberty to obey the forces by which they are impelled. These forces are, 1*st*, the attraction of the molecules on one another, according to the Newtonian law; and, 2*dly*, the centrifugal force generated by the revolution of the whole mass about a fixed axis; and the problem is, to determine the form which such a body, under the influence of these forces, would ultimately take. In order to obtain a solution of the question thus generally enunciated, it is necessary to know, *a priori*, the attractions of the different parts of the fluid body on one another. But the attraction of its different parts depends on their mutual arrangement; that is to say, on the internal constitution of the body or the variations of its density, and also on its form. Of the density in the interior of the earth we know little; and its form is the very element we are seeking to determine. This mutual dependence of the attraction of the mass on its form, and of its form on its attraction, renders it necessary to have recourse to certain arbitrary assumptions respecting the primitive figure of the earth and its internal structure, in order to deter-

mine the relation of the forces with which its different parts attract each other, and thence assign its figure, and the variations of gravity at the different points of its surface.

A fluid mass whose particles are impelled by no other forces than those which result from their mutual attractions, would assume (it is natural to suppose) a spherical form. Such at least would be a figure of equilibrium; for the surface of the sphere being everywhere at right angles to the directions of the attracting forces, which in this case all pass through the centre of gravity, a particle placed on its surface would have no tendency to move along the surface in any direction. But if the mass is made to revolve, the rotation gives rise to an extraneous force, tending to cause every particle to recede from the axis, and which acts with an energy on each particle directly proportional to the distance of the particle from the axis. Hence the attraction of the mass on each particle, in the direction perpendicular to the axis of rotation, is diminished, and the diminution is greatest towards the equatorial parts, where the distance from the axis is greatest. In order, therefore, that the equilibrium may be restored, an accumulation of matter must take place about the equator, so that the mass will bulge out in that quarter, and become flattened at the poles, where the force of attraction is not counteracted. This consideration led Newton to suppose the figure of the earth to be that of an oblate spheroid, or the figure that is generated by the revolution of an ellipse about its shorter axis.

Before proceeding with the investigation, it will be proper to inquire what are the conditions necessary to ensure the equilibrium of a mass of fluid matter, the particles of which are acted on by their mutual attractions and the centrifugal force of rotation. Conceive the particles of a body A to be solicited by accelerating forces of any kind. Suppose dm (which may be regarded as a rectangular parallelepipedon, having its faces parallel to the planes of the co-ordinates) to be one of the molecules of the mass, and x, y, z, the co-ordinates of the solid angle nearest the origin; then, putting $k =$ the density of the mass, we shall have $dm = k \,.\, dx\, dy\, dz$. Let X, Y, Z be the accelerating forces acting on dm in the direction parallel to the respective axes of the co-ordinates, then the motive forces in the direction of the same axes will be respectively $\mathrm{X}dm$, $\mathrm{Y}dm$, $\mathrm{Z}dm$.

Now let $p =$ the pressure in the direction of the axis of x, referred to the unit of surface; then $p \,.\, dydz$ is the whole pressure on the face $dydz$ of the element dm. But p may be regarded as a function of x, y, z; therefore at the point whose co-ordinates are $x + dx, y, z$, the pressure on the unit of surface is $p + \frac{dp}{dx} dx$, and consequently the whole pressure on the face of dm opposite to $dxdy$ is $\left(p + \frac{dp}{dx} dx\right) dydz$. The particle dm is thus urged in the direction of the axis of x by the two forces $p \,.\, dydz$ and $\left(p + \frac{dp}{dx} dx\right) dydz$, or by a force equal to their difference, namely, $\frac{dp}{dx} dxdydz$. In order, therefore, that dm may remain at rest, this last force or pressure must be exactly balanced by the motive force acting in the direction of the same axis; that is to say, we must have $\frac{dp}{dx} dxdydz = \mathrm{X}dm$ In the same manner, we must have $\frac{dp}{dy} dxdydz = \mathrm{Y}dm$, and $\frac{dp}{dz} dxdydz = \mathrm{Z}dm$; whence, since $dm = k \,.\, dx\, dy\, dz$, we deduce

$$\frac{dp}{dx} = k\mathrm{X},\ \frac{dp}{dy} = k\mathrm{Y},\ \frac{dp}{dz} = k\mathrm{Z} \ldots\ldots\ldots\ldots (a).$$

Let the first of these equations be multiplied by dx, the second by dy, and the third by dz, the sum of the products gives

$$dp = k\,(\mathrm{X}dx + \mathrm{Y}dy + \mathrm{Z}dz) \ldots\ldots\ldots\ldots\ldots (b).$$

The first member of this equation being an exact differential, it is necessary, in order that the equilibrium be possible, that the second member be an exact differential likewise. This, therefore, is a condition which must be satisfied.

At the surface of the mass the pressure p vanishes, and equation (b) becomes

$$0 = k\,(\mathrm{X}dx + \mathrm{Y}dy + \mathrm{Z}dz),$$

which expresses that the resultant of the three forces X, Y, Z, is perpendicular to the surface.

If the fluid is homogeneous, the density k is constant, and may be represented by unit. In this case equation (b) becomes

$$dp = \mathrm{X}dx + \mathrm{Y}dy + \mathrm{Z}dz,$$

and the equation of the surface is

$$\int (\mathrm{X}dx + \mathrm{Y}dy + \mathrm{Z}dz) = \text{constant.}$$

It will be remarked that this last equation does not belong merely to the exterior surface or to the homogeneous fluid: by giving a different value to the constant it will form the equation of any surface in the interior of a mass of heterogeneous fluid, at every point of which the pressure or the density is the same. For let the second member of equation (b) be a complete differential, and equal to kdf. We have then $dp = kdf$, whence k is necessarily a function of p and f. But on integrating the equation, f will be given in a function of p, consequently k must be a function of p. When therefore k is constant, p must be constant, or $dp = 0$; hence

$$\int (\mathrm{X}dx + \mathrm{Y}dy + \mathrm{Z}dz) = \text{constant.}$$

The different surfaces defined by this equation all possess the common property of intersecting at every point the resultant of the accelerating forces X, Y, Z at right angles; hence they are denominated *level surfaces.*

It follows, therefore, that when the above equation is satisfied, two conditions necessary to the equilibrium are fulfilled; namely, that the resultant of all the forces urging any particle in the interior of the mass is perpendicular to the level surface passing through that particle; and that the force acting on any particle of the surface is perpendicular to the surface. When the fluid is homogeneous, or the density equal throughout the mass, the first of these conditions is always satisfied, and the second is of itself sufficient. Writers on this subject have therefore in general considered that all the conditions necessary to ensure the equilibrium of a fluid mass, whether homogeneous or heterogeneous, revolving about a fixed axis, are comprehended in the single equation

$$\int (\mathrm{X}dx + \mathrm{Y}dy + \mathrm{Z}dz) = \text{constant};$$

and this is the view which has been taken of the question by Clairaut, D'Alembert, Lagrange, Laplace, Legendre, and Poisson. It has, however, been demonstrated by Mr Ivory, in an elaborate paper in the *Philosophical Transactions for* 1824, that when, as in the case of the earth, a mutual attraction exists among the constituent molecules of the mass, another condition must be fulfilled; and that the equilibrium will not necessarily take place, unless the figure of the mass is such, that any "interior body of the fluid, bounded by a level surface, be *in equili-*

brio with respect to the attraction of all the exterior matter." Hence, in addition to the equation derived from the principle of equal pressure in all directions, a second equation must be satisfied, in virtue of which every level stratum must possess such a figure as to attract all particles in the inside with equal force in opposite directions. Without having regard to this condition, the problem cannot be completely solved. (See also *Philosophical Magazine* for April 1825.)

Within the limits to which the present article must necessarily be confined, it would be in vain to attempt to give a general solution of this very intricate problem. We shall therefore content ourselves with demonstrating that all the conditions of equilibrium will be satisfied, if the figure of the earth (assumed to be fluid) is that of a spheroid of revolution of small ellipticity. We shall, first, suppose the fluid to be homogeneous; and, secondly, that its density is variable.

Prop. I.—A particle placed anywhere within a hollow solid of homogeneous matter, generated by the annular space comprised between two similar and similarly situated concentric ellipses revolving about their common axis, is attracted by the solid equally in all directions.

For let p (fig. 11) be such a particle, and ab any straight line passing through p, meeting the exterior surface in a and b, and the interior in c and d; then if ab be bisected in e, cd will also be bisected in e, because the figures are similar and similarly situated. Therefore $ac = db$. Now conceive ab to be the axis of two opposite pyramids having their vertices at p, and terminated by the surface at a and b, and let mn be an infinitely thin slice of the pyramid ab, formed by surfaces parallel to that of the given spheroid. The attraction of mn on p is directly as the surface mn and inversely as pm^2; but the surface mn is proportional to pm^2; therefore the attraction of p on the pyramidal slice mn is constant; hence the attraction of p on the whole frustum between a and c is proportional to the number of such slices, or to ac. In the same manner the attraction of p on the frustum between d and b is proportional to db. But $ac = db$; therefore p is attracted equally in both directions. The same thing being true of all other pyramids which have their vertices at p, it follows that the particle p is attracted equally in all directions, or remains at rest.

This property, which is true also of the sphere, and forms one of the necessary conditions of equilibrium, was first demonstrated by Newton in the *Principia*.

Prop. II.—To find the ratio of the axes of a homogeneous spheroid of revolution, when a fluid column from the equator to the centre balances the column from the pole to the centre, the spheroid being supposed to revolve about its minor axis, and its particles to attract one another with forces varying in the inverse ratio of their mutual distances.

Let PQ (fig. 12) be a meridian of the spheroid, of which the centre is C. Let us assume in the following propositions,

$P =$ the attraction of the spheroid at the pole, or gravity,
$Q =$ the attraction at the equator,
$\varphi =$ the centrifugal force at the equator,
$Q' = Q - \varphi$ the gravitation at the equator, or the attraction of the spheroid there diminished by the centrifugal force.

Let also

$a =$ CP half the polar axis,
$b =$ CQ the radius of the equator.

In CP take any point E, and make CE $= x$. It is demonstrated in the article Attraction (art. 8), that the force with which a particle at E is attracted towards C, is to that with which a particle at P is attracted in the same direction as CE to CP, or x to a; therefore the force at E $= P \cdot \frac{x}{a}$. Now if we suppose the area of a section of the column perpendicular to the axis $= 1$, the mass of the element of the column will be $1 \times dx = dx$, and its pressure will consequently be $P \frac{x}{a} dx$. Let this quantity be represented by du. On integrating, and observing that while x increases u diminishes, we find

$$u = \text{const.} - P \cdot \frac{x^2}{2a}.$$

At the surface $u = 0$ and $x = a$; therefore

$$0 = \text{const.} - P \cdot \frac{a^2}{2a};$$

whence, by subtraction, $u = P \cdot \frac{a^2 - x^2}{2a}$,

and consequently at the centre, where $x = 0$, $u = P \cdot \frac{a}{2}$.

In like manner, if in CQ we take a point F, and make CF $= y$, the force at F resulting from the attraction of the spheroid will be $Q \cdot \frac{y}{b}$. But the centrifugal force at F is to that at Q as CF to CQ, or as y to b; therefore the centrifugal force at F $= \varphi \cdot \frac{y}{b}$. Hence the force with which a particle at F is attracted towards the centre is $(Q - \varphi) \frac{y}{b}$ $= Q' \frac{y}{b}$, and the pressure of the element of the column $= Q' \frac{y}{b} dy$. Putting this $= du'$, and integrating as before, we find, at the centre, $u' = Q' \frac{b}{2}$. But, by hypothesis, at the centre $u' = u$; therefore $P \frac{a}{2} = Q' \frac{b}{2}$, whence $P : Q' = b : a$; that is to say, the attraction at the pole is to the gravitation at the equator as the radius of the equator to the radius of the pole.

Prop. III.—If the radius of the equator is to the radius of the pole as the attraction at the pole is to the gravitation at the equator, the resultant of all the forces which urge a particle situated any where on the surface of the spheroid is perpendicular to the surface.

Let D (fig. 10) be the particle, and PDQ the meridian passing through it. As the plane of the meridian divides the solid into two parts exactly alike in every respect, it is obvious that the particle can have no tendency to move out of that plane; we shall therefore only consider the direction of the force urging it in the plane of the meridian. Let DE be perpendicular to CP, and DF to CQ; and make CE $= x$, CF $= y$. It is demonstrated in the article Attraction (21 and 22), that the force which attracts D in the direction DF, perpendicular to the plane of the equator, is to the force at the pole as DF to CP, or as $x : a$; and that the force attracting D in the direction DE perpendicular to the axis is to the attraction at Q as DE to CQ, or as $y : b$; but the centrifugal force at D, which also acts in the direction DE, is to that at Q as DE to CQ; therefore, taking X to represent the whole force at D in the direction parallel to the axis, and Y that in the direction perpendicular to the axis, we have

$$X : P = x : a, \text{ and } Y : Q' = y : b,$$

 whence $X = P\frac{x}{a}$, $Y = Q'\frac{y}{b}$. In QC take the point N such that FN : FD = Y : X; then FN : FD $= Q'\frac{y}{b} : P\frac{x}{a}$, or FN $\cdot x$: FD $\cdot y$ = $Q'a : Pb$, whence, since FD = x, and FC = y, FN : FC = $Q'a : Pb$. But by hypothesis $Q' : P = a : b$, therefore FN : FC = $a^2 : b^2$, whence by the well-known properties of the ellipse FN is the subnormal, and DN the normal or perpendicular to the surface of the spheroid at D.

Corollary. If the attraction at the pole is represented by CP, then the force at any point D on the surface, in the direction perpendicular to the surface, is proportional to DN the normal passing through D. It is also proportional to DM (the normal produced till it meets the axis); for, by conic sections, DM : DN = $b^2 : a^2$; that is, DM has to DN a constant ratio.

The proposition which has now been demonstrated is sufficient for the equilibrium of a homogeneous fluid mass revolving about an axis. It may, however, be shown directly, that when the above condition is fulfilled, any particle in the interior of the mass will be equally urged in all directions, or will remain at rest. Thus:—

Prop. IV.—If the radius of the equator is to the radius of the pole as the attracting force at the pole is to gravitation at the equator, the pressure which any point D in the interior of the spheroid sustains from the fluid in canals of any form, extending from that point to the surface, is the same for every canal.

Let DD'd (fig. 13) be a canal drawn from any point D in the interior of the spheroid to D' and d in the surface. Let x', y', z' be the rectangular co-ordinates of D, and x'', y'', z'' those of D'. Take F and f, any two points in the canal indefinitely near each other, and let x, y, z be the co-ordinates of F; then $x + dx$, $y + dy$, and $z + dz$ are those of f. Now X, Y, and Z being the resultants of the forces acting on F in the directions of the co-ordinates, the forces X, Y, Z will be reduced to the direction of the canal at F by multiplying them respectively by the cosines of the angles which that direction makes with the axes, that is, by $\frac{dx}{du}$, $\frac{dy}{du}$, $\frac{dz}{du}$, (u representing the canal). Hence the accelerating force acting on F in the direction of the canal is $X\frac{dx}{du} + Y\frac{dy}{du} + Z\frac{dz}{du}$; and supposing the area of a section of the canal = 1, the pressure produced by the action of this force on the fluid contained in the portion of the canal Ff is $du\left(X\frac{dx}{du} + Y\frac{dy}{du} + Z\frac{dz}{du}\right)$. But, by what has been demonstrated in the article Attraction (9), $X = P\frac{x}{a}$, $Y = Q'\frac{y}{b}$, $Z = Q'\frac{z}{b}$; therefore, denoting the whole pressure of the canal on F by p, and observing that p diminishes as F is nearer the surface, we have

$$-dp = du\left(P\frac{x}{a}\cdot\frac{dx}{du} + Q'\frac{y}{b}\cdot\frac{dy}{du} + Q'\frac{z}{b}\frac{dz}{du}\right),$$

and integrating,

$$p = \text{const.} - P\frac{x^2}{2a} - Q'\frac{y^2 + z^2}{2b}$$

At the point D this becomes

$$p = \text{const.} - P\frac{x'^2}{2a} - Q'\frac{y'^2 + z'^2}{2b},$$

and at D', where $p = 0$,

$$0 = \text{const.} - P\frac{x''^2}{2a} - Q'\frac{y''^2 + z''^2}{2b};$$

therefore, by subtraction,

$$p = P\frac{x''^2 - x'^2}{2a} + Q'\frac{y''^2 - y'^2 + z''^2 - z'^2}{2b}.$$

Now the equation of the surface of the spheroid gives

$$x''^2 = \frac{a^2}{b^2}\left\{b^2 - (y''^2 + z''^2)\right\},$$

whence

$$P\frac{x''^2}{2a} = P\frac{a}{2} - P\frac{a(y''^2 + z''^2)}{2b^2},$$

and, by hypothesis, $P : Q' = b : a$, or $Pa = Q'b$; therefore

$$P\frac{x''^2}{2a} = P\frac{a}{2} - Q'\frac{y''^2 + z''^2}{2b};$$

and on substituting this in the above expression of the value of p, we get, finally,

$$p = P\frac{a}{2} - P\frac{x'^2}{2a} - Q'\frac{y'^2 + z'^2}{2b}.$$

This equation being independent of the form of the canal, and of the situation of the point D', will necessarily be the same for every canal extending from D to the surface of the spheroid; consequently the point D sustains the same pressure in all directions.

From what has now been demonstrated, it appears that a fluid spheroid of uniform density, revolving about its lesser axis, and whose particles attract one another with forces varying in the inverse ratio of the distances, will be *in equilibrio* when the gravity at the pole is to the gravity at the equator diminished by the centrifugal force there, as the equatorial axis to the polar axis. The equation of equilibrium of such a spheroid is therefore $Pa = Q'b$; and from this we shall now proceed to determine the ratio of the axes, or of $a : b$, corresponding to a given velocity of rotation.

Let ϵ be the eccentricity, that is, let $\epsilon^2 = \frac{b^2 - a^2}{a^2}$, whence $b^2 = a^2(1 + \epsilon^2)$. It is demonstrated in the article Attraction (23 and 24), that

$$P = 4\pi a\frac{1 + \epsilon^2}{\epsilon^3}(\epsilon - \text{arc tan. }\epsilon)$$

$$Q = (Q' + \varphi) = 2\pi b\frac{1 + \epsilon^2}{\epsilon^3}\left(\text{arc tan. }\epsilon - \frac{\epsilon}{1 + \epsilon^2}\right),$$

the density of the mass being 1, and π the semicircumference of a circle whose radius is unit. Now if t denote the time of a revolution, we shall have, from the theory of central forces, $\varphi = \frac{4\pi^2}{t^2}b$; and making $\frac{\pi}{t^2} = m$, we get $\varphi = 4\pi bm$, whence

$$Q' = 2\pi b\left\{\frac{1 + \epsilon^2}{\epsilon^3}\left(\text{arc tan. }\epsilon - \frac{\epsilon}{1 + \epsilon^2}\right) - 2m\right\}.$$

Substituting these values of P and Q' in the equation $Pa = Q'b$, it becomes

$$4\pi a^2\frac{1 + \epsilon^2}{\epsilon^3}(\epsilon - \text{arc tan. }\epsilon) =$$

$$2\pi b^2\left\{\frac{1 + \epsilon^2}{\epsilon^3}\left(\text{arc tan. }\epsilon - \frac{\epsilon}{1 + \epsilon^2}\right) - 2m\right\};$$

whence, putting $a^2(1 + \epsilon^2)$ instead of b^2, and neglecting the common factors, we get

$$\text{arc tan. }\epsilon = \frac{3\epsilon + 2m\epsilon^3}{3 + \epsilon^2}\ldots\ldots\ldots\ldots(1).$$

In order to discover whether this equation, which is transcendental, has a real root, or how many, we may put

$$\beta = \frac{3\epsilon + 2m\epsilon^3}{3 + \epsilon^2} - \text{arc tan. }\epsilon\ldots\ldots\ldots(2),$$

and suppose the curve to be described, of which ϵ is the absciss, and β the ordinate. This curve will evidently cut the axis at the origin of the co-ordinates; for when $\epsilon=0$, we have also $\beta=0$; but the root $\epsilon=0$ has no concern with the question; for the velocity, and consequently ϵ, is supposed to be a real quantity. By changing the sign of ϵ, the value of β undergoes no alteration, whence the curve has two equal and similar branches on opposite sides of the origin; we need therefore attend only to the positive values of ϵ. If then we suppose ϵ to increase from nothing to infinity, the value of β will begin and end with being positive, whence between these two values of ϵ the curve will either not cut the axis at all, or cut it an even number of times; or, which is the same thing, the equation has either no roots, or an equal number.

To find the values of ϵ corresponding to the greatest and least values of β, we must make $d\beta=0$. Differentiating equation (2), we get, after arranging the terms,

$$\frac{d\beta}{d\epsilon}=\frac{2\epsilon^2\{m\epsilon^4+(10m-2)\epsilon^2+9m\}}{(1+\epsilon^2)(3+\epsilon^2)^2};$$

whence, making $d\beta=0$,

$$m\epsilon^4+(10m-2)\epsilon^2+9m=0\ldots\ldots\ldots\ldots\ldots(3),$$

the two roots of which are

$$\epsilon^2=5-\frac{1}{m}\pm\sqrt{\left(5-\frac{1}{m}\right)-9.}$$

Since these are the only roots of equation (3), it follows that there can be only one maximum and one minimum value of the ordinate β on each side of the origin of the abscissa. Hence we infer that the curve intersects the positive abscissa only in two points exclusive of the origin; so that there are two, and only two, real and positive roots of the equation (1). Thus there are two forms of the oblate spheroid, which, for a given velocity of rotation, satisfy the condition of equilibrium; a curious result, which was first made known by Legendre.

The limits within which the roots of equation (1) are possible will be obtained by determining the values of ϵ and m at the point where the curve touches the axis of the abscissa without cutting it. At this point $\beta=0$, and $d\beta=0$. When $d\beta=0$, equation (3) gives

$$m=\frac{2\epsilon^2}{\epsilon^4+10\epsilon^2+9}=\frac{2\epsilon^2}{(1+\epsilon^2)(9+\epsilon^2)}\ldots\ldots\ldots(4);$$

substituting this in (2), and making $\beta=0$, we get, after reduction,

$$\text{arc tan. }\epsilon=\frac{7\epsilon^5+30\epsilon^3+27\epsilon}{(3+\epsilon^2)(1+\epsilon^2)(9+\epsilon^2)},$$

or, dividing the terms by $(3+\epsilon^2)$,

$$\text{arc tan. }\epsilon=\frac{7\epsilon^3+9\epsilon}{(1+\epsilon^2)(9+\epsilon^2)};$$

an equation which can have only one positive root besides $\epsilon=0$. On solving it by approximation we easily find, on a few trials,

$$\epsilon=2\cdot5292;$$

whence, from equation (4), the corresponding value of m is

$$m=0\cdot11234.$$

From this we conclude that, when the value of m is smaller than 0·11234, the equation (1) has two unequal positive roots; that when m is equal to this number, the two roots become equal, or the two intersections of the curve with the axis pass into a contact; and that when m is greater than 0·11234, equation (1) has no real roots, or the equilibrium is impossible.

When the eccentricity ϵ is a very small fraction, as in the case of the earth, the values of the quantities denoted by P and Q may be developed in series proceeding according to the powers of ϵ, and converging rapidly. Because (see ALGEBRA, sect. XXV. (H 2)

$$\text{arc tan. }\epsilon=\epsilon-\frac{\epsilon^3}{3}+\frac{\epsilon^5}{5}-,\ \&\text{c.}$$

and because

$$\frac{\epsilon^2}{1+\epsilon^5}=\epsilon-\epsilon^3+\epsilon^5-,\ \&\text{c.}$$

the preceding expression for P becomes

$$P=4\pi a\,.\,\frac{1+\epsilon^2}{\epsilon^3}\left(\frac{\epsilon^3}{3}-\frac{\epsilon}{5}+\ \&\text{c.}\right);$$

whence, on multiplying, and rejecting all terms involving higher powers of ϵ than the square,

$$P=4\pi a\left(\frac{1}{3}+\frac{2}{15}\epsilon^2\right)=\frac{4\pi a}{3}\left(1+\frac{2}{5}\epsilon^2\right).$$

Making the same substitutions in the value of Q, we find

$$Q=2\pi b\,\frac{1+\epsilon^2}{\epsilon^3}\left(\frac{2}{3}\epsilon^3-\frac{4}{5}\epsilon^5+,\ \&\text{c.}\right),$$

and multiplying as before,

$$Q=2\pi b\left(\frac{2}{3}-\frac{2}{15}\epsilon^2\right)=\frac{4\pi b}{3}\left(1-\frac{1}{5}\epsilon^2\right).$$

Now, if instead of ϵ we introduce the ellipticity e, and make $e=\frac{b-a}{a}$, we shall have $b=a\,(1+e)$. But we have already assumed $b^2=a^2\,(1+\epsilon^2)$; whence $1+e=\sqrt{1+\epsilon^2}$: and on rejecting the second and all the higher powers of e (which may be done because e is supposed to be a very small fraction), we have $1+2e=1+\epsilon^2$, and consequently $2e=\epsilon^2$. Substituting this in the above formulas, and observing that $b=a\,(1+e)$, we get

$$P=\frac{4\pi a}{3}\left(1+\frac{4}{5}e\right);\quad Q=\frac{4\pi a}{3}\left(1+\frac{3}{5}e\right);$$

and since $\varphi=4\pi bm=4\pi a\,(1+e)\,m=4\pi am$ (for m and e being both very small fractions, their product me may be neglected), we have also

$$Q'=Q-\varphi=\frac{4\pi a}{3}\left(1+\frac{3}{5}e-3m\right).$$

Substituting these values of P and Q' in the equation of equilibrium, $Pa=Q'b=Q'a\,(1+e)$, there results

$$1+\frac{4}{5}e=(1+e)\left(1+\frac{3}{5}e-3m\right);$$

whence, rejecting terms multiplied by e^2 and em, we find

$$e=\frac{15}{4}m.$$

The ratio of the centrifugal force to gravitation at the equator is $\frac{\varphi}{Q'}$, or $\frac{3m}{1+\frac{3}{5}e-3m}=3m$; hence $e=\frac{5}{4}\cdot\frac{\varphi}{Q'}$; that is to say, the ellipticity of a homogeneous spheroid revolving about an axis, and whose form does not differ greatly from that of a sphere, is equal to the fraction formed by dividing five times the centrifugal force at the equator by four times the gravitation at the equator. By comparing the length of the arc described by a point on the earth's surface in a second of time, with the descent of falling bodies, Newton found this ratio in the case of the earth to be $\frac{1}{289}$, whence $m=\frac{1}{3\times289}=\frac{1}{867}$, and consequently $e=\frac{15}{4}\times\frac{1}{3\times289}=\frac{1}{231}$, so that, supposing the earth to be homogeneous, the ratio of its polar to its equatorial axis ought to be 230 to 231 very nearly.

Figure of the Earth.

The ellipticity deduced from the actual measurements of degrees, as well as from the variations of gravity indicated by pendulum observations, is considerably less than $\frac{1}{231}$; consequently the earth is not homogeneous.

In what precedes, we have supposed generally $m = \frac{\pi}{t^2}$, and found for the limit which m cannot exceed, $m = 0{\cdot}11234$. Let m' be what m becomes in the case of the earth, and t' be the time (expressed in parts of a mean solar day) in which the earth makes one revolution about its axis; t being the time in which a spheroid of the same mean density as the earth would make a revolution when $m = 0{\cdot}11234$. We have then $m' = \frac{\pi}{t'^2}$, whence $m' : m = t^2 : t'^2$, whence $t = t'\sqrt{\frac{m'}{m}}$. But $t' = 23$ h. 56 m. 4 sec. $= {\cdot}99727$ day; and we have already found $m' = \frac{1}{867}$; therefore $t = {\cdot}99727\sqrt{\frac{1}{867 \times 0{\cdot}11234}} = 0{\cdot}1009$ day $= 2$ hours 25 minutes 26 seconds. Hence a fluid mass of the same density as the earth could not be in equilibrium with the figure of an ellipsoid of revolution if its time of rotation were less than 2 h. 25 m. 26 sec. If the time of rotation is greater, there are two elliptic spheroids, and not more, which, with the same velocity of rotation, give a figure of equilibrium.

Hitherto we have considered only one of the roots of equation (1), and seen that it gives 230 : 231 as the ratio of the polar to the equatorial axis. Let us now inquire into the value of the other root.

As the value of ε^2 in the former case was very small, it will now be large; we may therefore proceed as follows: The identical equation

$$\text{arc tan. } \varepsilon = \frac{1}{2}\pi - \text{arc tan.} \frac{1}{\varepsilon}$$

gives

$$\text{arc tan. } \varepsilon = \frac{1}{2}\pi - \frac{1}{\varepsilon} + \frac{1}{3\varepsilon^2} - \frac{1}{5\varepsilon^5} +, \text{ \&c.}$$

whence equation (1) becomes

$$\frac{3\varepsilon + 2m\varepsilon^3}{3\,\varepsilon^2} = \frac{1}{2}\pi - \frac{1}{\varepsilon} + \frac{1}{3\varepsilon^2} - \frac{1}{5\varepsilon^5} +, \text{ \&c.}$$

Reverting this series, in order to find ε in a series proceeding by the powers of m, we get

$$\varepsilon = \frac{\pi}{4m} - \frac{8}{\pi} + \frac{12m}{\pi}\left(1 - \frac{64}{3\pi^2}\right) +, \text{ \&c.}$$

or

$$\varepsilon = {\cdot}785398\,\frac{1}{m} - 2{\cdot}546479 - 4{\cdot}436656\,m.$$

Relatively to the earth, it has been seen that $m = \frac{1}{867}$; by substituting which in the above equation, we find $\varepsilon = 680$ nearly; so that $\sqrt{1+\varepsilon^2}$, the ratio of the equatorial to the polar axis, is 680 : 1. In this case the spheroid is extremely flattened.

In the preceding propositions it has been demonstrated that a fluid mass of uniform density revolving about a fixed axis will be *in equilibrio*, if its form is that of an oblate spheroid, provided the velocity of rotation does not exceed a certain limit, which has been ascertained. But it has been remarked, that if the same relation exists between the attraction and the centrifugal force as exists in the case of the earth, the ellipticity of such a spheroid would be different from the actual ellipticity of the earth, as determined by observation. It follows that the terrestrial spheroid must be heterogeneous, or of variable density; and this supposition is rendered more probable by what is otherwise known of the nature of the earth. The difficulties of the problem are however greatly increased in the case of a heterogeneous fluid; indeed it is only brought within the power of analysis by assuming that the form of the revolving mass differs very little from that of a sphere, and that it is regularly composed of concentric layers, increasing in density from the surface towards the centre, according to a determinate law. Admitting these assumptions, it may be demonstrated that the oblate spheroid of revolution is in this case also a figure of equilibrium.

The demonstration will be greatly simplified by means of the two following propositions respecting the attraction of homogeneous spheroids of small ellipticity, and which are easily deduced from the properties demonstrated in the article ATTRACTION.

PROP. V.—To find the measure of the attractive forces that urge a particle situated any where within or in the surface of a homogeneous oblate spheroid of revolution, in the directions parallel and perpendicular to the axis, the ellipticity being small.

Let D be the particle, x and y its rectangular co-ordinates (x being taken along the axis, and y perpendicular to the axis, in the meridional plane passing through D); let also X and Y denote the attractive forces soliciting the particle in those directions, and $k =$ the density of the spheroid.

By ATTRACTION (25), $P : X = a : x$, and $Q : Y = b : y$; therefore $X = P\frac{x}{a}$ and $Y = Q\frac{y}{b}$. But it has been already shown, that when the elipticity is small,

$$P = \frac{4\pi}{3}a\left(1 + \frac{4}{5}e\right),\; Q = \frac{4\pi}{3}a\left(1 + \frac{3}{5}e\right),$$

therefore

$$X = \frac{4\pi}{3}x\left(1 + \frac{4}{5}e\right);\; Y = \frac{4\pi}{3}\frac{a}{b}y\left(1 + \frac{3}{5}e\right).$$

Introducing the density k, to which the attraction is directly proportional, and observing that $\frac{a}{b} = \frac{1}{1+e}$, these expressions become

$$X = \frac{4\pi}{3}kx\left(1 + \frac{4}{5}e\right);\; Y = \frac{4\pi}{3}ky\left(1 - \frac{2}{5}e\right).$$

PROP. VI.—To find the measure of the forces with which an oblate spheroid, whose ellipticity is small, attracts a particle situated any where without it, in the direction parallel to the axis, and in the direction perpendicular to the axis, the density being uniform.

Let PQ (fig. 14) be the given spheroid, of which the axes are a and b, D the given point without the spheroid, and x' y' the co-ordinates of D. From the two assumed equations $b'^2 - a'^2 = b^2 - a^2$, and $\frac{x'^2}{a'^2} + \frac{y'^2}{b'^2} = 1$, find a' and b', and conceive another spheroid P′Q′ to be described whose polar and equatorial semidiameters are respectively a' and b', whose centre coincides with that of the given spheroid, and which has its equator in the same plane. The surface of this spheroid, in consequence of the equation $\frac{x'^2}{a'^2} + \frac{y'^2}{b'^2} = 1$, will necessarily pass through the point D. Make $x = \frac{ax'}{a'}$, $y = \frac{by'}{b'}$; then, by what is demonstrat-

ed in ATTRACTION (26), the point D′, whose co-ordinates are x and y, is in the surface of the given spheroid PQ; and the attraction of the spheroid PQ on a particle at D is to the attraction of the spheroid P′Q′ on the point D′, as $b^2 : b'^2$ in the direction perpendicular to the equator, and as $ab : a'b'$ in the direction perpendicular to a plane passing through the axis. If, therefore, we denote by X and Y the attractions of the given spheroid PQ on D, and by X′ and Y′ those of the spheroid P′Q′ on D′, in the directions of the co-ordinates x and y respectively, we shall have

$$X : X' = b^2 : b'^2, \text{ and } Y : Y' = ab : a'b',$$

consequently

$$X = \frac{b^2}{b'^2} X', \; Y = \frac{ab}{a'b'} Y'.$$

But by the last proposition,

$$X' = \frac{4\pi}{3} kx \left(1 + \frac{4}{5} e'\right), \; Y' = \frac{4\pi}{3} ky \left(1 - \frac{2}{5} e'\right)$$

(e' being the ellipticity of the spheroid P′Q′p'); therefore

$$X = \frac{4\pi}{3} \frac{b^2}{b'^2} k \left(1 + \frac{4}{5} e'\right) x, \; Y = \frac{4\pi}{3} \frac{ab}{a'b'} k \left(1 - \frac{2}{5} e'\right) y;$$

and, on substituting for x and y their values $\frac{a}{a'} x'$ and $\frac{b}{b'} y'$, we have

$$X = \frac{4\pi}{3} \frac{ab^2}{a'b'^2} k \left(1 + \frac{4}{5} e\right) x'; \; Y = \frac{4\pi}{3} \frac{ab^2}{a'b'^2} k \left(1 - \frac{2}{5} e\right) y'.$$

We must now eliminate from these equations the quantities a', b', and e', by means of the three equations of condition $\frac{x'^2}{a'^2} + \frac{y'^2}{b'^2} = 1$, $b'^2 - a'^2 = b^2 - a^2$, and $b' = a'(1 + e')$. In order to abridge, let r = CD, the distance of D from the centre of the spheroid, and θ = the angle DCP. We have then $x = r \cos. \theta$, $y = r \sin. \theta$, and the first of the above equations becomes $r^2 (b'^2 \cos.^2 \theta + a'^2 \sin.^2 \theta) = a'^2, b'^2$, which, since $b' = a'(1 + e')$, and consequently $b'^2 = a'^2 (1 + 2e')$, reduces to $r^2 (1 + 2e' \cos.^2 \theta) = a'^2 (1 + 2e')$. On dividing by $1 + 2e'$, and neglecting terms multiplied by e^2, this gives $a'^2 = r^2 (1 - 2e' \sin.^2 \theta)$, and consequently $a'^2 e' = r^2 e'$.

But $b'^2 = a'^2 (1 + 2e')$, therefore $b'^2 - a'^2 = 2a'^2 e'$; and in like manner, $b^2 - a^2 = 2a^2 e$; whence, by reason of $b'^2 - a'^2 = b^2 - a^2$, we have $a'^2 e' = a^2 e$; consequently $a^2 e = r^2 e'$, and $e' = \frac{a^2}{r^2} e$. Substituting this value of e' in the equation $a'^2 = r^2 (1 - 2e' \sin.^2 \theta)$, we get $a'^2 = r^2 - 2a^2 e \sin.^2 \theta$; whence, neglecting terms in e^2, $a' = r - \frac{a^2 e \sin.^2 \theta}{r}$. From the equation $a'^2 = r^2 (1 - 2e' \sin.^2 \theta)$ we also get $b'^2 - a'^2 = b'^2 - r^2 (1 - 2e' \sin.^2 \theta)$; but $b'^2 - a'^2 = 2a'^2 e' = 2a^2 e$; therefore $2a^2 e = b'^2 - r^2 (1 - 2e' \sin.^2 \theta)$, and consequently $b'^2 = r^2 + 2a^2 e \cos.^2 \theta$.

From these values of a' and b'^2 we find, on multiplying and neglecting terms involving the square and higher powers of e, $a' b'^2 = r^3 + 2a^2 re \cos.^2 \theta - a^2 re \sin.^2 \theta = r^3 + ra^2 e (2 - 3 \sin.^2 \theta)$. But $b^2 = a^2 (1 + 2e)$, and $ab^2 = a^3 (1 + 2e)$, therefore

$$\frac{ab^2}{a'b'^2} \left(1 + \frac{4}{5} e'\right) = \frac{ab^2}{a'b'^2} \left(1 + \frac{4a^2}{5r^2} e\right)$$
$$= \frac{a^3}{r^3} \left\{1 + 2e - e \frac{3a^2}{5r^2} (2 - 5 \sin.^2 \theta)\right\},$$

and

$$\frac{ab^2}{a'b'^2} \left(1 - \frac{2}{5} e'\right) = \frac{ab^2}{a'b'^2} \left(1 - \frac{2a^2}{5r^2} e\right)$$
$$= \frac{a^3}{r^3} \left\{1 + 2e - e \frac{3a^2}{5r^2} (4 - 5 \sin.^2 \theta)\right\}.$$

Substituting these expressions in the above values of X and Y, writing $r \cos. \theta$ for x', and $r \sin. \theta$ for y', we get

$$X = \frac{4\pi}{3} k \frac{a^3}{r^2} \left\{1 + 2e - e \frac{3a^2}{5r^2} (2 - 5 \sin.^2 \theta)\right\} \cos. \theta,$$

$$Y = \frac{4\pi}{3} k \frac{a^3}{r^2} \left\{1 + 2e - e \frac{3a^2}{5r^2} (4 - 5 \sin.^2 \theta)\right\} \sin. \theta.$$

Thus the expression of the force with which a homogeneous spheroid attracts a point placed without it has been found in finite terms. The ingenious process of analysis by which this result, of very great importance in the theory of the figures of the planets, has been obtained, is one of the many discoveries for which mathematical science is indebted to Mr Ivory.

PROP. VII.—To find the measure of the forces with which an oblate spheroid whose ellipticity is small, attracts a particle situated any where on its surface, in the direction parallel to the axis, and in the direction perpendicular to the axis, the density being variable.

In the solution of this problem we suppose the spheroid to be composed of infinitely thin concentric layers, bounded by spheroidal surfaces of different ellipticities, and that the density is uniform for a single layer, but variable from one layer to another.

Let P′Q′ (fig. 15) be the given spheroid, a', b' its polar and equatorial radii, and D the attracted point. Let D′ be any point within the spheroid P′Q′, and PQD′ be a spheroidal surface at every point of which the density is the same, a, b its polar and equatorial radii, and e its ellipticity. Also let p, q be another spheroidal surface indefinitely near PQ, of which the polar radius C$p = a + da$, the equatorial C$q = b + db$, and the ellipticity $= e + de$. Between the two surfaces PQ and pq the density k may be supposed constant.

In order to find the attraction of the whole spheroid on D, we must first find expressions in terms of a for the forces with which D is attracted by the elementary layer PQpq; the integration of these expressions from $a = 0$ to $a = a'$ will give the attractions of the spheroid.

Conceive for a moment the density of the spheroid CPQ to be uniform and $= k$. The forces X and Y with which this spheroid attracts D are given by the last proposition, and the forces with which Cpq attracts D will be found by substituting $a + da$ for a, and $e + de$ for e in the same expressions for X and Y. Now, as the ellipticity varies from C to P′, e may be regarded as a function of a; its variation is consequently included in the variation of a, and the attractions of the spheroid Cpq hence become

$$X + \frac{dX}{da} da, \; Y + \frac{dY}{da} da.$$

The difference between the attractions of the spheroids Cpq and CPQ is the attraction of the layer PQqp, which is therefore $\frac{dX}{da} da$, and $\frac{dY}{da} da$. Hence, if we represent the attractions of the whole heterogeneous spheroid CP′Q′ by X′ and Y′, we shall have

$$X' = \int \frac{dX}{da} da, \; Y' = \int \frac{dY}{da} da,$$

which integrals must be taken from $a = 0$ to $a = a'$, the density k, which enters as a factor into X and Y, being regarded as a function of a.

Let us first consider the force X′. By last proposition we have

$$X = \frac{4\pi}{3} k \frac{a^3}{r^2} \left\{1 + 2e - e \frac{3a^2}{5r^2} (2 - 5 \sin.^2 \theta)\right\} \cos. \theta,$$

whence

$$\frac{dX}{da}da=\frac{4\pi k}{3\,r^2}\left\{d(\overline{1+2e}.a^3)-\frac{3}{5r^2}(2-5\sin.^2\theta)d(a^5e)\right\}\cos.\theta.$$

Integrating, and regarding k as variable, and a function of a, and going through the same process with respect to Y, we get for the attractions of the spheroid CP′Q′ in the directions respectively parallel and perpendicular to the axis,

$$X'=\frac{4\pi}{3}\left\{\frac{1}{r^2}\int kd(\overline{1+2e}.a^3)-\frac{3(2-5\sin.^2\theta)}{5r^4}\int kd(a^5e)\right\}\cos.\theta,$$

$$Y'=\frac{4\pi}{3}\left\{\frac{1}{r^2}\int kd(\overline{1+2e}.a^3)-\frac{3(4-5\sin.^2\theta)}{5r^4}\int kd(a^5e)\right\}\sin.\theta.$$

Prop. VIII.—To find the measure of the forces with which a heterogeneous layer, included between two level surfaces, attracts a particle situated anywhere within it.

Let D′ (fig. 15) be the given particle situated within the spheroidal layer PQQ′P′, x' and y' the co-ordinates of D′, a = polar semiaxis, and e = eccentricity of the inner surface PQ passing through D′, a' = polar semiaxis of the exterior surface P′Q′, and k = density at the interior surface.

Suppose the interior of the spheroid PQ to be filled with matter of uniform density k, then by Proposition V., the attractions of that spheroid on D′ are

$$X=\frac{4\pi}{3}k\left(1+\frac{4}{5}e\right)x',\ Y=\frac{4\pi}{3}k\left(1-\frac{2}{5}e\right)y';$$

or, changing x' into r cos. θ, and y' into r sin. θ,

$$X=\frac{4\pi}{3}r'k\left(1+\frac{4}{5}e\right)\cos.\theta,\ Y=\frac{4\pi}{3}rk\left(1-\frac{2}{5}e\right)\sin.\theta.$$

Now the attraction of another similar spheroid Cpq, whose polar semiaxis is $a+da$, will be found by substituting $a+da$ for a and $e+de$ for e in the above expressions; and the attraction of the elementary layer PQpq on D will be the difference of these attractions. But

$$\frac{dX}{da}da=\frac{4\pi}{3}\cdot\frac{4}{5}rkde\cos.\theta,$$

$$\frac{dY}{da}da=-\frac{4\pi}{3}\cdot\frac{2}{5}rkde\sin.\theta,$$

e being regarded as a function of a. The integral of these expressions will give the attraction of the layer PQqp on D′; but as this attraction diminishes while a increases, if we take A to represent what $\int kde$ becomes when a becomes a', and denote by X″ and Y″ the attractions of the whole layer PQQ′P′, we shall have

$$X''=\frac{4\pi}{3}\cdot\frac{4}{5}r\left(A-\int kde\right)\cos.\theta,$$

$$Y''=-\frac{4\pi}{3}\cdot\frac{2}{5}r\left(A-\int kde\right)\sin.\theta.$$

Prop. IX.—To find the attraction of a heterogeneous spheroid on a point within it.

Let D′ (fig. 14) be the given point, and CP′Q′ the given spheroid, r cos. θ and r sin. θ the co-ordinates of D′, a', and e', the polar semiaxis and ellipticity of the given spheroid CP′Q′, and a and e those of the spheroidal surface passing through D′ and all the points of equal density.

The whole force urging D′ may be conceived as made up of two parts; that arising from the spheroid CPQ, the surface of which passes through D, and that of the spheroidal shell PQQ′P′. The first of these forces is given by the expressions represented by X′ and Y′ in Prop. VII. and the second by the expressions represented by X″ and Y″ in Prop. VIII. Therefore, if we denote by X‴ and Y‴ the attractions of the whole spheroid on the particle D′, in the direction parallel to the axis, and in the direction perpendicular to the axis, we shall have

$$X'''=X'+X'',\quad Y'''=Y'+Y'';$$

and if the spheroid revolves about its polar axis, Y‴ must be diminished by the amount of the centrifugal force $=\frac{4\pi}{3}\cdot\frac{3\pi}{t^2}r\sin.\theta$; therefore the attractions of the given spheroid on the point D′ are

$$X'''=X'+X'',$$

$$Y'''=Y'+Y''-\frac{4\pi}{3}\cdot\frac{3\pi}{t^2}r\sin.\theta.$$

Prop. X.—To find the ratio of the ellipticity to the density of any level surface, when the component of all the forces urging any point on the surface is perpendicular to the surface.

The forces urging the particle D′ (fig. 14) being X‴ and Y‴, in order that their resultant may be perpendicular to the surface, we must have

$$X''':Y'''=\text{ME}:\text{ED (fig. 10)}.$$

But ME (the subnormal)$=\frac{b^2}{a^2}x'=(1+2e)x'$, and ED$=y'$; therefore $X''':Y'''=(1+2e)x':y'$, whence, substituting r cos. θ for x' and r sin. θ for y', $\frac{X'''}{\cos.\theta}-\frac{Y'''}{\sin.\theta}(1+2e)=0$.

Now, if we substitute for X‴ in this equation the values of X′ and X″ given by Propositions VII. and VIII., and for Y‴ the values of Y′ and Y″ multiplied by $(1+2e)$, and neglect terms involving e^2, we shall find, on changing the signs and having regard to the centrifugal force,

$$\frac{2e}{r^2}\int kd(\overline{1+2e}.a^3)-\frac{6}{5r^4}\int kd(a^5e)-\frac{6}{5}r\left(A-\int kde\right)-\frac{3\pi r}{t^2}=0.$$

Dividing by $2r$, and substituting a for r (which may be done without sensible error, because all the terms of the equation are small, and because r^2 differs from a^2 only by a quantity depending on the ellipticity e), we shall find

$$\frac{e}{a^3}\int kd(\overline{1+2e}.a^3)-\frac{3}{5a^5}\int kd(a^5e)-\frac{3}{5}\left(A-\int kde\right)-\frac{3\pi}{2t^2}=0.$$

From this we infer that if k and e have the relation to each other indicated by this equation, and that e is very small from $a=0$ to $a=a'$, each of the level surfaces will be intersected at every point by the resultant of the attractive forces under an angle which will differ from a right angle only by an infinitesimal of the second order, supposing the centrifugal force to be very small in comparison of gravity. Hence, neglecting quantities of the second order, the elliptical spheroid (supposing the equation possible) is a figure of equilibrium.

In order to discover whether the equation which has now been obtained is possible, it must be differentiated twice in order to eliminate $\int kd(a^5e)$ and $\int kde$, both of which contain the ellipticity e. Observing that as the first term is multiplied by e, we may suppose, without sensible error, $\frac{e}{a^3}\int kd(\overline{1+2e}.a^3)=\frac{e}{a^3}\int kd(a^3)=\frac{3e}{a^3}\int ka^2da$, and the first differentiation gives, on multiplying by a^6,

$$\frac{de}{da}a^3\int ka^2da-3a^2e\int ka^2da+\int kd(a^5e)=0.$$

Differentiating again, and considering da as constant, we shall find, after reduction,

$$\frac{d^2e}{da^2}+\frac{2ka^2}{\int ka^2da}\cdot\frac{de}{da}+\left(\frac{2ka}{\int ka^2da}-\frac{6}{a^2}\right)e=0.$$

This is the equation given by Clairaut (*Figure de la Terre*, p. 276). It can be integrated by the usual methods when k is expressed in terms of a; consequently the equilibrium is always possible if the density is a function of the distance from the centre. The integration being performed, an equation will result between the densities and ellipticities of the different spheroidal layers, by means of which, when one of these elements is supposed to be given, the other can be determined.

PROP. XI.—To find the whole force urging a particle situated at any point on the surface of a heterogeneous spheroid revolving about its shorter axis.

By Prop. VII. the force urging the particle in the direction of the axis is X', and in the direction perpendicular to the axis Y'; but in consequence of the centrifugal force, the latter becomes $Y'-\varphi$, therefore the whole force urging D in the direction of the normal

$$=\sqrt{X'^2+(Y'-\varphi)^2}.$$

Neglecting the terms which involve e^2 and $e\varphi$ (φ being small as well as e), and putting $\int kd(\overline{1+2e}\cdot a^3)=M$, and $\int kd(a^5 e)=N$, and substituting $\frac{4\pi^2}{t^2}r\sin.\theta$ for φ, we get

$$X'^2=\left(\frac{4\pi}{3r^2}\right)^2\left\{M^2\cos.^2\theta-\frac{6(2-5\sin.^2\theta)}{5r^2}MN\cos.^2\theta\right\},$$

$$(Y'-\varphi)^2=\left(\frac{4\pi}{3r^2}\right)^2\left\{M^2\sin.^2\theta-\frac{6(4-5\sin.^2\theta)}{5r^2}MN\sin.^2\theta-\frac{6M\pi r^3\sin.^2\theta}{t^2}\right\};$$

whence, putting $X^2+(Y-\varphi)^2=U^2$, there results

$$U^2=\left(\frac{4\pi}{3r^2}\right)^2\left\{M^2-\frac{6(2-3\sin.^2\theta)}{5r^2}MN-\frac{6M\pi r^3\sin.^2\theta}{t^2}\right\},$$

and extracting the square root,

$$U=\frac{4\pi}{3}\left\{\frac{M}{r^2}-\frac{3(2-3\sin.^2\theta)}{5r^4}N-\frac{3\pi r\sin.^2\theta}{t^2}\right\}.$$

But the equation of the ellipse gives

$$r^2\cos.^2\theta+\frac{r^2\sin.^2\theta}{1+2e}=a^2;$$

whence we deduce $r^2=a^2(1+2e\sin.^2\theta)$; therefore, substituting and dividing, and neglecting terms in Ne and $e\varphi$,

$$U=\frac{4\pi}{3}\left\{\frac{M}{a^2}(1-2e\sin.^2\theta)-\frac{3}{5}\cdot\frac{(2-3)\sin.^2\theta}{a^4}N-\frac{3\pi^2 a\sin.^2\theta}{t^2}\right\}.$$

Let the centrifugal force at the equator $=m\times$ gravity; then, if m is a very small fraction (as in the case of the earth, where $m=\frac{1}{289}$), terms involving the product me may be neglected, and the last equation, multiplied by m, will become

$$mU=\frac{4\pi}{3}\cdot\frac{M}{a^2}m;$$

but the centrifugal force at the equator $=\frac{4\pi^2}{t^2}a(1+e)$, which does not differ sensibly from $\frac{4\pi^2}{t^2}a$; therefore $\frac{4\pi^2}{t^2}a=\frac{4\pi}{3}\frac{M}{a^2}m$, or $\frac{3\pi}{t^2}=\frac{Mm}{a^3}$. Now, at the surface the equation of equilibrium in Prop. X. becomes

$$\frac{e}{a^3}M-\frac{3}{5a^5}N-\frac{3\pi}{2t^2}=0$$

therefore

$$\frac{e}{a^3}M-\frac{3}{5a^5}N-\frac{Mm}{2a^3}=0,$$

whence

$$\frac{3N}{5a^4}=\frac{M}{a^2}\left(e-\frac{m}{2}\right).$$

Substituting these values of $\frac{3\pi}{t^2}$ and $\frac{3N}{5a^4}$ in the above value of U, we get, after reduction,

$$U=\frac{4\pi}{3}\cdot\frac{M}{a^2}\left\{1-2e+m-\left(\frac{5}{2}m-e\right)\sin.^2\theta\right\}.$$

At the equator $\sin.\theta=1$, and this equation becomes

$$Q=\frac{4\pi}{3}\cdot\frac{M}{a^2}\left\{1-e-\frac{3}{2}m\right\};$$

and at the pole, where $\sin.\theta=0$, it gives

$$P=\frac{4\pi}{3}\cdot\frac{M}{a^2}\left\{1-2e+m\right\};$$

consequently the difference between the force of gravity at the pole and that of gravitation at the equator is $\frac{4\pi}{3}\cdot\frac{M}{a^2}\left(\frac{5m}{2}-e\right)$. Dividing this by the polar gravity P, we get for the quotient $\frac{5m}{2}-e$, which, therefore, expresses the ratio of the excess of the polar gravity above the gravitation at the equator to the gravity at the pole. Let this ratio $=n$, we have then

$$n=\frac{5}{2}m-e;$$

a very remarkable relation between the gravity and ellipticity, which was discovered by Clairaut, and is generally called *Clairaut's theorem.*

If we substitute $1-\cos.^2\theta$ for $\sin.^2\theta$ in the equation

$$U=\frac{4\pi}{3}\cdot\frac{M}{a^2}\left\{1-2e+m-\left(\frac{5}{2}m-e\right)\sin.^2\theta\right\},$$

we get

$$U=\frac{4\pi}{3}\cdot\frac{M}{a^2}\left\{1-e-\frac{3}{2}m+\left(\frac{5}{2}m-e\right)\cos.^2\theta\right\};$$

or, neglecting quantities of the order me,

$$U=\frac{4\pi}{3}\cdot\frac{M}{a^2}\left(1-e-\frac{3}{2}m\right)\left\{1+\left(\frac{5}{2}m-e\right)\cos.^2\theta\right\};$$

whence we have $U=Q(1+n\cos.^2\theta)$. Now in this equation the angle θ may be taken for the complement of the latitude, from which indeed it differs only by a quantity of the second order, and the equation then becomes $U=Q(1+n\sin.^2 l)$; whence we infer that, on going from the equator towards the pole, the increase of gravity is proportional to the square of the sine of the latitude.

Let p be the length of the seconds pendulum at the equator, p' its length at any latitude l, and U the intensity of the gravitating force at the same latitude l. When the time of oscillation is constant, the length of the pendulum is directly proportional to the intensity of gravity; therefore $p':p=U:Q$, and consequently

$$\frac{p'-p}{p}=\frac{U-Q}{Q}.\quad\text{But } U=Q(1+n\sin.^2 l),$$

therefore, $\frac{p'-p}{p}=n\sin.^2 l=\left(\frac{5m}{2}-e\right)\sin.^2 l.$

At the pole $\sin.l=1$, and $\frac{p'-p}{p}=\frac{5m}{2}-e$; therefore, since $e=\frac{b-a}{a}$, $\frac{p'-p}{p}+\frac{b-a}{a}=\frac{5m}{2}.$

Now it has been shown that in the case of a homogeneous spheroid the ellipticity is $\frac{5\,m}{4}$; hence we have this theorem:

In the case of a heterogeneous spheroid, the excess of the length of the pendulum at the pole above its length at the equator divided by its length at the equator, and the excess of the axis of the equator above the polar axis divided by the polar axis, form two fractions, of which the sum is constant, and equal to twice the ellipticity the spheroid would have if homogeneous.

SECTION IV.

ON THE FIGURE OF THE EARTH AS DETERMINED BY OBSERVATIONS OF THE PENDULUM.

As the various methods of determining the length of a pendulum which makes a given number of vibrations in a mean solar day, and the corrections that are required to reduce the observations to the same circumstances in respect of altitude, temperature, barometric pressure, &c. form the subject of a separate article, we shall here limit ourselves to a brief abstract of the results of some of the latest and best observations.

The ellipticity of the earth is deduced from the observed number of vibrations made by an invariable pendulum of a given length at different latitudes, by means of the theorem of Clairaut. Let $N =$ the number of oscillations made by a pendulum at the equator in a mean solar day, $N' =$ the number of oscillations made by the same pendulum at the latitude l; then Q representing, as before, the gravitation at the equator, and U the gravitation at latitude l, we have, by the last proposition in the preceding section,

$$U = Q\,(1 + n \sin.^2 l).$$

But by the property of the invariable pendulum, the square of the number of vibrations is directly proportioned to the force of gravitation; therefore $U : Q = N'^2 : N^2$, whence $N'^2 = N^2\,(1 + n \sin.^2 l)$.

In this equation $n = \frac{5}{2}\,m - e = \frac{5}{2 \times 289} - e$; therefore, as N'^2 is given by observation at any station, we can, by combining the results at two different latitudes, determine N and n, and consequently e. The pendulum gives no information respecting the magnitude of the earth.

Instead of N and N′, we might substitute in the above equation the lengths of the seconds pendulum at the equator, and the latitude l (the length of the seconds pendulum being also directly proportional to the intensity of gravity); but as the invariable pendulum is now almost universally employed for the measurement of the variations of gravity, the formula under the above form is more immediately applicable to the results of observation. The absolute length of the pendulum (which is not very easily determined) has no concern with the present question.

For the purpose of exhibiting the variations of gravity, we shall confine our attention to the results that have been found from observations with the invariable pendulum. The results given by pendulums of a different kind are probably not less exact, but they are not directly comparable, on account of the great uncertainty that remains respecting the correction that ought to be applied for the buoyancy of the atmosphere.

In the seventh volume of the *Memoirs of the Royal Astronomical Society*, Mr Baily has given the results of fourteen different sets of observations with invariable pendulums. They are as follows:

1. The observations of Captain Kater at different stations in Great Britain. These are detailed in the *Philosophical Transactions* for the year 1819.

2. Those of Mr Goldingham at London and Madras, and of Mr Lawrence and Mr Robinson with the same pendulum at the small island of Pulo Guansah Lout, on the western coast of Sumatra, and almost immediately under the equator. (*Phil. Trans.* 1822.)

3. Those of Captain Hall at the Galapagos Islands, San Blas, Rio Janeiro, and London. (*Phil. Trans.* 1823.)

4. Those of Sir Thomas Brisbane at London and Paramatta. (*Phil. Trans.* 1823.)

5. Those of Captain Sabine in various parts of the Atlantic Ocean and the North Sea, in the years 1822–4. (Sabine's *Account of Experiments*, &c. 1825.)

6. Those of Captain Foster at Greenwich, London, and Port Bowen. (*Phil. Trans.* 1826.)

7. Those of Mr Fallows at the Cape of Good Hope. The same pendulum was swung in London previous to its departure.

8, 9, 10. Those of Captain Sabine for the purpose of determining the difference in the number of oscillations at London and Paris (*Phil. Trans.* 1828), London and Greenwich (*Phil. Trans.* 1829), and at Greenwich, London, and Altona (*Ibid.* 1829 and 1830).

11. Those of Captain Freycinet, who commanded an expedition fitted out by the French government in 1817, for the purpose of making scientific observations in a voyage round the world. The stations at which the experiments were made were the island of Rawak (near the coast of Guinea), Guam (one of the Ladrones), the Isle of France, Mowi (one of the Sandwich Islands), Rio Janeiro, Port Jackson, Cape of Good Hope, Paris, and the Falkland Islands. (*Voyage autour du Monde, par M. Freycinet.*)

12. Those of Captain Duperrey, who commanded another French expedition. The stations were, island of Ascension, Isle of France, Port Jackson, Toulon, Paris, and the Falkland Islands. (*Connoissance des Tems* for 1830.)

13. Those of Captain Leutke, a Russian officer, under whose orders a ship of war was dispatched to the South Seas, for the purpose, among other things, of swinging the pendulum at various places. The stations at which experiments were made were Ualan (one of the Caroline Isles), Guam, St Helena, Bonin Island (off the south-east coast of Japan), Valparaiso, Greenwich, Petropaulouski, Sitka (off the north-west coast of America), and Petersburg. (Mr Baily's Report in the *Memoirs of the Royal Astronomical Society*, vol. vii.)

14. Those of Captain Foster, in his last voyage, which commenced in 1828, and which form perhaps the most valuable series of the whole. The observations were made at fourteen different stations, principally in the southern hemisphere, from the equator to the latitude of 63°. Captain Foster carried out with him four pendulums, two of brass, one of iron, and one of copper, and at seven of the stations all four were swung. The details are published at full length in the volume of the *Astronomical Society's Memoirs* to which we have already referred, with an excellent Report by Mr Baily.

The results of all these observations are contained in the following table, in which the observed number of vibrations at each station is corrected, for any deviation from the standard temperature of 62°, or from the true correction for the buoyancy of the atmosphere, and afterwards reduced to a comparison with Captain Foster's mean pendulum, assumed as making 86,400 vibrations in a mean solar day at London.

No.	Station.	Latitude.	Vibrations. Observed.	Vibrations. Computed.	Difference.	Observer.
1	Rawak	0° 1′ 34″ S.	86261·46	86264·86	— 3·40	Freycinet.

75	Drontheim	63 25 54 N.	86438·64	86442·20	— 3·56	Sabine.
76	Hammerfest	70 40 5 —	86461·14	86462·23	— 1·09	Sabine.
77	Fort Bowen	73 13 39 —	86470·48	86468·06	+ 2·42	Foster.
78	Greenland	74 32 19 —	86470·72	86470·75	— 0·03	Sabine.
79	Spitzbergen	79 49 58 —	86483·28	86479·58	+ 3·70	Sabine.

Taking the mean results of the observed vibrations given in col. 4 of the above table, and forming with each of them the equation of condition $N'^2 = N^2 (1 + n \sin.^2 l)$, seventy-nine equations are formed, from which, on deducing the values of N^2 and n by the method of least squares, Mr Baily obtained the following results:

$$N^2 = 7441625711$$
$$n = \cdot 00514491$$
$$e = \frac{1}{285\cdot 26}$$

By means of these values of N^2 and n, the number of vibrations made by a pendulum which beats seconds at London, at any latitude l, supposing the earth to be a regular spheroid, is given by the formula

$$N' = 86246\cdot 8 (1 + \cdot 00514491 \sin.^2 l)^{\frac{1}{2}};$$

and from this the results given in col. 5 of the table have been computed.

Although the differences between the observed and computed vibrations are in some instances considerable, the observations are on the whole well represented by supposing the ellipticity $= \frac{1}{285\cdot 26}$ To be satisfied of this, it will be sufficient to remark, that as the differences in the table present twenty-four alternations of sign, the curve which represents all the observations intersects the meridian having that ellipticity no less than twenty-four times along an arc of 152° (from Spitzbergen to South Shetland), or, on an average, once for every $6\frac{1}{4}$ degrees; and (with the exception of the island of Bonin) the deviations on the opposite sides are nearly equal.

If, instead of seeking an ellipticity by the *fusion* (if we may so speak) and agglomeration of all the observations by the method of least squares, we consider the results of the different voyagers separately, we shall find marked differences among them. Taken by themselves, Captain Sabine's observations give $e = \frac{1}{288\cdot 4}$; Captain Foster's, $e = \frac{1}{289\cdot 5}$; Duperrey's, $e = \frac{1}{266\cdot 4}$; Freycinet's, $e = \frac{1}{267\cdot 6}$; and Leutke's, $e = \frac{1}{267\cdot 7}$. The singular agreement of the results of the foreign voyagers with each other, and their difference from those of Captains Sabine and Foster, which also agree well with each other, have not been satisfactorily explained.

In one of the numbers of the *Annales des Sciences d'Observation* (tome i. No. 3), M. Saigey has computed the ellipticity from fifty-one different observations, combined by the method of least squares. Captain Foster's observations are of course not included in the table; but it contains those of Biot, made with a variable pendulum at different stations along the French and British arcs of meridian, and more recently in Italy and the Lipari Islands. The result gives $e = \frac{1}{286\cdot 5}$.

The differences between the observed and computed values are, in many instances at least, too great to be ascribed entirely to errors of observation. They must, therefore, be occasioned by real differences in the intensity of gravity, arising either from variations in the density of the materials which compose the exterior crust of the earth, or from local deviations of its form from that of the regular spheroid. On attending to the preceding table, it will be perceived that the differences are generally in excess where the station is on small islands, and especially if situated at a great distance from the main land. From this it may be inferred, that such islands are composed of denser materials than the general crust of the earth; but it is not improbable that part of this effect may be occasioned by a difference of the level of the surface of the ocean. On the shores of elevated continents, the direction of gravity is altered by the action of the high land; and the surface of the water, which is perpendicular to gravity, deviates from the regular curvature, and becomes elevated above the general level of the ocean. Hence the apparent elevation is less than the real elevation of the station, and the observed intensity of gravity is consequently less than it was calculated to be. How far the disturbing influence of this cause may affect the results, will be better understood when we shall be furnished with numerous pendulum observations, made in the interior of the large continents, and at a great distance from the sea.

All the pendulum experiments agree in giving a greater ellipticity to the earth than that which is deduced from the comparison of arcs of meridian. To what cause this discrepancy is to be assigned is by no means apparent. The geological character of the country in the immediate neighbourhood of the station probably exerts a considerable influence in accelerating or retarding the pendulum; but the experiments have now been made at so many points, that we might expect to find the effects of local irregularities almost entirely eliminated, and a much nearer agreement between the results of the two methods of investigation than actually exists. We can, however, have no difficulty in giving the preference to the results of the geodetic measures.

It was mentioned in the first section of this article that the ellipticity of the earth may be deduced from certain inequalities in the motions of the moon, to which it gives rise; but this part of the subject belongs to the theory of the lunar perturbations. The ellipticity so deduced is about $\frac{1}{300}$, which agrees well with that given by the meridional arcs; and the result has the advantage of being entirely independent of local disturbance.

One conclusion cannot fail to be drawn from the results of this enquiry. However irregular the surface of the earth may be in its details, its general form agrees so nearly with the figure of hydrostatic equilibrium, that the agreement cannot be regarded as fortuitous or accidental. The regular increase of gravity from the equator to the poles, indicated by the pendulum experiments, also proves that it is symmetrically constituted, or that the materials in its interior are disposed about the centre of gravity in regular elliptical strata, and arranged according to the order of density. The earth must therefore have taken its present form while its particles were at liberty to arrange themselves in obedience to the forces arising from their mutual attractions and from the rotation; in other words, it must have existed at some period of time in a state of fluidity. This inference, which so many geological facts tend to confirm, may be extended to all the other planets.

(T. G.)

FILAMENT. See FIBRE.

FILANGIERI, GAETANO, celebrated for his valuable works on political economy and legislation, was born at Naples on the 18th of August 1752. He was the third son of Cesar prince of Araniello, by Marianna Montalto, daughter of the Duke of Fragnito. Gaetano from his infancy was destined for the profession of arms; when he was seven years of age he was enrolled in one of the royal regiments, and commenced actual service at the age of fourteen. His education was at first neglected, from a misconception of his character, which was supposed to be averse to all literary or speculative pursuits. A lucky accident, however, not only removed this impression but showed that his former impatience of the modes of tuition then in use arose from the clearness and vigour of his judgment. It happened that his brother's preceptor had one day mistaken the solution of some geometrical problem. Gaetano immediately perceived the source of this error, which he demonstrated to the master. This incident, apparently trivial, determined his future destiny. Encouraged by his success, he quitted the military service, and determined to follow his natural taste for science and philosophy. So diligent was he in repairing the defects of his education, that at twenty years of age he had acquired a knowledge of Greek and Latin, of ancient and modern history, of the great principles both of civil and of public law, and was besides well initiated in mathematical science. Although his genius inclined him solely to the study of legislation and policy, he sacrificed his views to the wishes of his friends, and entered on the profession of the law, which was then the certain road both to honour and fortune. His eloquence and his extensive knowledge soon obtained him success; and about this period a circumstance happened which greatly conduced to his celebrity. Enormous abuses prevailed in the judicial proceedings at Naples, arising from the uncertainty of the law, which occasioned constant misconceptions, and almost always led to arbitrary judgments. By a wise ordinance of the king, passed in the year 1774 at the suggestion of the minister Tanucci, those abuses were reformed; the law was restored to its proper authority; its judgments were freed from the control of precedents; and the judges were ordained in every case to publish the grounds of their decisions. Although this reform was generally applauded, it excited the murmurs of the bar. Filangieri now became the advocate of the court, and published a defence of the royal decree, founded upon the most enlarged views of equity and reason. The extensive knowledge and matured judgment displayed in this performance attracted the attention of the ministers, and Filangieri was encourged to pursue the course in which he had already acquired so much distinction. Through the influence of his uncle, the Archbishop of Palermo, he was in 1777 placed in an honourable office at court; and almost at the same time he was named officer of the royal corps of marine volunteers, who were more particularly attached to the king's person. But his abode at court neither broke in upon his regular habits of life, nor interrupted the course of his studies; nor did he allow it to interfere with the composition of the great work on legislation and government in which he was engaged, and to which for several years he had devoted all his inquiries. About the commencement of the eighteenth century a great school of philosophy had been formed at Naples, in which the principles of the civil law, of the law of nations, and of legislation, were established on the solid and comprehensive basis of general utility. From this school numerous works of celebrity have proceeded; amongst others, the great work of Beccaria, which, though confined to one branch of legislation, contains principles which are of universal application. There was still wanting, however, a general treatise on legislation, for the purpose of examining the science in all its relations, and of laying down some common and universal principles of equity and expediency as its only true basis; and it was to this important undertaking that Filangieri's philosophical mind was now directed. His subject he proposed to divide into seven books. The first, in which he demonstrates the general rules of legislation, and the second, which treats on political laws, and on those laws also which are connected with the general structure of society, appeared at Naples in 1780; and such was its popularity, that not only in Italy, but throughout Europe at large, the author was ranked among the most celebrated writers on public law. According to his theory, the goodness of laws is either absolute or relative. It is absolute when they are agreeable to those great and universal principles of equity and expediency which are obligatory on man under every diversity of country, climate, government, or manners; it is relative, according as the laws agree with the nature of the government, with the genius and character of the people, with the climate, with the fertility or sterility of the soil, with the physical circumstances of the country, with the religion of the inhabitants, and with the degree of civilization to which they have advanced. In his second book, which treats of political laws, and of those laws also which are connected with the general economy of society, he examines two points; namely, the state of population and of wealth. With respect to the first point, the great question which he considers is, whether Europe is as populous as it might be? This question he resolves in the negative, and he proceeds to explain the causes of this deficient population. According to his hypothesis, the state of agriculture affords in every country the surest evidence as to the state of the population; but the backwardness of agriculture in most parts of Europe sufficiently indicates that the population is deficient; therefore he infers the defective state of European legislation on these two capital points. The great obstacles to the improvement of agriculture, and, consequently, to the increase of population, he considers to be, 1*st*, the small number of proprietors, and the great number of non-proprietors; 2*dly*, too many large, and too few small properties; 3*dly*, the exorbitant and inalienable possessions of the church in several states; 4*thly*, the excess of the public imposts, and the violent modes of levying them; 5*thly*, to these he adds other causes of less importance, such as the state of most of the regular troops of the European states; also public corruption, and the dissoluteness of private morals. The progress of agriculture, the great source of wealth as well as of population, may also be obstructed by a bad political administration, by bad laws, or by those causes which occasion a great influx of inhabitants to the respective capitals of the different states. It belongs to a pure system of legislation to remove some of these obstacles, and to counterbalance such others as are inevitable, by suitable encouragements. Having discussed these momentous questions, he next enters into a comprehensive survey of the other sources of riches, namely, arts, manufactures, and commerce, and points out how these may be obstructed by at faulty legislation, and, at the same time, the means by which such obstructions may be removed. In order fully to comprehend the merits of these performances, we must consider that all the faults which the author reprehends were committed by his own government; a circumstance which imposed on him the delicate task of stating obnoxious truths with freedom and boldness, and, at the same time, without giving unnecessary offence. So well, however, did he appreciate the views of those whom it was his wish to enlighten, that he was immediately promoted by the king to a commandery in the royal order of Constantine. In 1783 he married a Hungarian lady of noble birth, who was entrusted with the education of the second daughter of the king, and who to outward attractions united the gift of a sound judgment and an agreeable disposition. That he might the more freely enjoy domestic happiness, and at the

same time have leisure for the composition of his work, on which he became every day more intent, he resigned, with the consent of the king, all his military employments and his office at court, and retired to a country-seat about 20 miles from Naples. In the same year he published his third book, relating entirely to the principles of criminal jurisprudence. In these discussions he maintains the same tone of decision and independence as before. Abuses are freely pointed out, and the defects of the penal code, and the forms of criminal procedure, are fairly exposed. In thus pointing out those defects in the domestic administration of his government, Filangieri excited the hatred of an interested and powerful class; and a proposition which he made in his third book, for the reformation of abuses in the Roman Catholic Church, drew down upon his work the censure of some of the ecclesiastical tribunals. In 1785, however, he published the fifth, sixth, and seventh volumes of his work, which comprehended his fourth book. These were devoted to the consideration of education, morals, and public instruction; and though on these important points we may be occasionally disposed to question his views, we must nevertheless admire his mild and philosophical spirit still opposed to every excess, his extensive knowledge, and his happy talent of arranging and combining it for the illustration of his argument; his animated, flowing, and perspicuous style; and, above all, that rectitude and philanthropy which are diffused over all his reasonings. His fifth book, which treated of the laws relative to religion, was soon afterwards published. But his health was now considerably impaired, owing to an excess of application, so that the remainder of his work advanced but slowly; and other interruptions soon followed. In the year 1787 he was called by the new king, Ferdinand IV., to the supreme council of finance. He returned to Naples, and from that time was wholly engrossed with the important business of this office. His health, already injured, was soon completely broken by severe and active application; and several domestic misfortunes, operating upon a mind of deep sensibility, at last threw him into a state of melancholy. He finally retired from all business into the country, where he soon afterwards became seriously ill, and on the 21st of July 1788 he expired. Before his death he had finished the eighth volume of his work, containing the first part of the fifth book, in which he treats of the different systems of religion that preceded Christianity. Of the second part of the same book he had only made a rude sketch, in which were noted down the principal subjects of discussion; namely, the advantages of Christianity and the dangers of superstition; the inconveniences of mixing spiritual with temporal concerns; the excessive riches of the clergy, and the immense increase of their power. He was also to examine the foundation of ecclesiastical rights, and to present, in a new system of legislation, a remedy for the abuses which he pointed out. A chapter on toleration would have terminated this book. In his sixth book he proposed to treat of the laws relative to property; and in his seventh and last, of the nature of the paternal power and the government of families. He had also other important works in contemplation when his course was terminated by death. Filangieri, besides some of the rarest gifts of genius, was endowed by nature with the additional advantage of a most imposing presence. His manners were eminently graceful and dignified. His countenance bore the traces of habitual reflection, and of deep sensibility, mingled with an expression of soft melancholy. In private life nothing could exceed the simplicity of his character, except the animation and interest of his conversation. See *La Scienza della Legislazione*, Livorno, 1807, 5 tomes 8vo. This is the last Italian edition of Filangieri's great work. There is a French translation in 7 vols. 8vo, published at Paris in 1798, from the Neapolitan edition of 1784. The first two books have been translated into English, under the title of *The Science of Legislation*, from the Italian of Filangieri, and published in 2 vols. 8vo, Lond. 1806. (D. B—N.)

FILBERT, the fruit of the cultivated hazel. See HAZEL.

FILE, a well-known instrument of steel for cutting and abrading metal, ivory, wood, &c. Files are of various forms, sizes, and cuts, according to the uses to which they are to be applied. When the surface is cut in transverse furrows by a straight sharp-edged chisel and mallet, the instrument is properly called a file; but when it is raised by a triangular punch, it is termed a rasp. This last kind is chiefly employed for rubbing wood and horn. The larger kinds of files are made of blistered steel; but the small and fine files of cast steel. Various ingenious machines have been contrived for cutting the teeth of files, but these have not hitherto succeeded so well as to supersede file-making by the hand. After the file has been cut it must undergo the process of tempering. This is said to be well effected in the following manner: A saturated solution of common salt, stiffened to the consistence of cream with ale grounds, or with any cheap farinaceous matter, such as bean-flour (some use well-dried chimney-soot), is to be spread over the file, in order to preserve its surface from oxidation during the process; it is then uniformly heated in a coke or charcoal fire to a cherry-red colour; and on its removal from the fire it is to be suddenly quenched in cold and pure spring water. It is subsequently cleaned with charcoal and a rag; after which it is laid up in wheat bran to preserve it from rust. When the file is intended to cut iron or steel, it is found preferable to substitute animal carbon for the grounds or farinaceous matter mentioned above. This will give even to iron a superficial hardness sufficient for any kind of file.

FILIAL PIETY. Ancient history furnishes many extraordinary instances of this amiable virtue.

The Roman dictator T. Manlius, having exercised great cruelty over the citizens, was cited at the expiration of his office to answer for his conduct. Among a number of things laid to his charge, he was accused of treating with barbarity one of his own sons. All were highly exasperated against Manlius, excepting the son himself, who, under the greatest concern lest he should furnish grounds of accusation against his father, resolved to put a stop to the proceedings. Going to the house of the tribune Pomponius, who had accused his father, while Pomponius was yet in bed, he was immediately admitted by the tribune, who did not doubt but he was come to discover some new instances of his father's severity; but young Manlius drew out a dagger and declared he would stab Pomponius to the heart if he did not swear, in the form he should dictate, never to hold the assembly of the people for accusing his father. Pomponius, when he saw the dagger glittering at his breast, was compelled to yield, and took the oath demanded of him.

Amongst the multitude of persons who were proscribed at Rome under the second triumvirate, were Cicero and his brother Quintus. But the latter found means to conceal himself so effectually at home, that the soldiers could not discover him. Enraged at their disappointment, they put his son to the question, in order to make him disclose the place of his father's concealment; but filial affection remained proof against the most exquisite tortures. An involuntary sigh, and sometimes a deep groan, was all that could be extorted from the youth. Quintus, who was close at hand, when he heard the sighs and groans of a son expiring in tortures to save his life, quitted his place of concealment, and, presenting himself to the assassins, beseeched them to dismiss the innocent youth, and to take his life instead; but the only answer to this appeal was that they must both die. Then a new contest of tenderness arose

who should die first; but this the assassins soon decided, by beheading them both at the same time.

Epaminondas, in the midst of the applause bestowed on him after his splendid victory over the Spartans at Leuctra, with an unaffected simplicity that marked the greatness of his character, observed—"My joy arises from my sense of that which the news of my victory will give my father and my mother."

Among an incredible number of illustrious persons who were put to death by the tyrant Nero, was Barea Soranus, a man noted for his justice and integrity. During his confinement, his daughter Servilia was apprehended on the charge that she had converted into money all her ornaments and jewels, to defray the expense of consulting magicians. To this the young Servilia with tears replied that she had indeed consulted magicians, but for the sole purpose of discovering whether the emperor and senate would afford protection and safety to her beloved parent against his accusers. "With this view," said she, "I presented the diviners with my jewels, apparel, and other ornaments, as I would have presented my blood and my life, could my blood and life have procured my father's liberty. If this be a crime, my father was an utter stranger to it, I alone am the delinquent." Notwithstanding this affecting appeal, she was condemned to die along with her father, but in what manner history is silent.

Valerius Maximus likewise mentions a very singular circumstance connected with this subject. A woman of illustrious birth had been condemned to be strangled. But the jailor who was ordered to execute her, being struck with compassion, resolved rather to let her perish of hunger. He also permitted her daughter to visit her, taking care, however, that the former brought nothing in the shape of sustenance. As this continued many days, he was surprised that the prisoner should live so long; but having narrowly watched the daughter, he discovered that she nourished her mother with her own milk. On the fact being made known, the criminal was pardoned, and a decree was passed that the mother and daughter should be maintained for the rest of their lives at the public expense.

The same author gives a similar instance of filial piety in a young woman called Xantippe towards her aged father Cimonus, likewise confined in prison, and which is commonly known by the name of the *Roman charity*. Both these instances appeared so extraordinary to that people, that they could only account for them by supposing that the love of children to their parents was the first law of nature. *Putaret aliquis*, says the author cited, *hoc contra naturam factum esse, nisi prima naturæ lex esset diligere parentes.*

FILIBEG, or PHILIBEG. See PHILIBEG.

FILICAJA, VINCENZO DA, a celebrated Italian poet, descended of a noble family of Florence, was born in that city on the 30th of December 1642. He commenced his studies under the Jesuits at Florence, and completed them in the university of Pisa. Grecian and Roman antiquity, philosophy, theology, and jurisprudence, were successively the objects of his study; poesy served merely as a relaxation from severer pursuits. Like most young devotees of the muses, he began with amatory verses; but the lady whom he loved and celebrated having died in the flower of her age, he burned all the verses which he had inscribed to her, and resolved henceforth to sing only heroic or sacred themes, a resolution which he most religiously observed. Having returned to Florence, after a residence of about five years at Pisa, he was received into the academy Della Crusca, and, in a short time, married a daughter of the senator Scipio Capponi; but as this lady brought him little fortune, and his own means were limited, he withdrew entirely from the world on the death of his father, and established himself in the country, where he divided his time between his studies, the education of his children, and the contemplation of the wonders of nature and its Author. He every day composed verses either in Latin or Italian, which he submitted to the judgment of his friends, and improved according to the advice which they gave, without any desire for publication, or indeed any other object than that of exercising his own powers. But a memorable occurrence drew him from the voluntary obscurity in which he had buried himself. Vienna, besieged by an army of 200,000 Turks, was delivered by John Sobieski, king of Poland, and by Charles, afterwards fifth Duke of Lorraine. This great event, which saved Christendom from the most imminent danger, excited the enthusiasm of Filicaja, who, in a magnificent *canzone* or ode, celebrated the victory of the Christian armies; he also addressed a second to the Emperor Leopold I., a third to the King of Poland, a fourth to the Duke of Lorraine, and a fifth to the God of Armies; and, the Ottomans having been entirely defeated in another battle, he celebrated this new triumph in a sixth ode, which is perhaps the most beautiful of all. These six triumphal odes excited universal admiration. The grand duke, of his own accord, sent copies of them to the princes whose exploits were commemorated, and from the latter the author received the most flattering acknowledgments. But as the copies of his odes became daily deformed by new errors, in proportion as they were multiplied, his friends at length obtained permission to print them. They accordingly appeared at Florence in 1684, in 4to; and Filicaja was, almost in spite of himself, placed in the first rank of Italian lyric poets. Another great ode, which he addressed the same year to Queen Christina of Sweden, fully supported the reputation which he had gained by his former productions. This princess, who then exhibited in private life the generosity of a sovereign, did not confine herself to a mere expression of her satisfaction, or corresponding with the author, or admitting him into the academy which she had formed at Rome of men most distinguished in poetry and letters: being informed of the depressed state of his circumstances, she in some sort adopted his two sons, undertook to defray the expense of their education, and exacted from their father, as the only expression of his gratitude, that he would maintain the most profound silence, not choosing, as she said, to have to blush before the public for having done so little to serve a man who had so many claims to her esteem. But a severe malady with which he was seized some years afterwards, was followed by another subject of affliction, which he felt much more sensibly; he lost his eldest son, who had been appointed page to the grand duke after the death of the queen his benefactress. This bereavement, which he bore with Christian fortitude, fixed on him the particular attention of the prince, who, interested in his fortune, conferred on him the dignity of senator, and soon afterwards appointed him ducal commissary of Volterra, then commissary of Pisa, and, lastly, secretary *au tirage* to the magistrates, an important office, which gave him immediate access to the prince, and initiated him in the secrets of the government. Filicaja, in all his employments, secured at once the gratitude of the public, the attachment of those under him, and the esteem of his sovereign. Neither the multiplicity of his occupations, nor the progress of age, however, prevented him from dedicating several hours each day to the cultivation of letters and the exercise of his poetical talent; but as his piety, which had always been great, increased with his years, he at length confined his reading to religious books, and treated only of sacred subjects. Nevertheless, he had resolved to collect all his pieces, to revise and correct them anew, and to publish himself a complete edition of his lyrical compositions; but, whilst occupied with this undertaking, in which he had made considerable progress, he was seized with a violent affection in the chest, which in a few days put a period to his life. He died at Florence on the 24th of September

1707, in the sixty-fifth year of his age, and was interred in the family vault in the church of St Peter, where his son Scipio erected a monument to his memory. The edition of his poetical works in Italian, which he was preparing, and had even begun to print at the time of his death, was also speedily published by the same son, who dedicated it to the Grand Duke Cosmo III., under the title of *Poesie Toscane di Vincenzo da Filicaja, senatore Fiorentino et accademico della Crusca*, Florence, 1707, in 4to. They were reprinted in 1720, with a life of the author, by Thomas Bonaventuri, a Florentine; which life had previously appeared in the second volume of the *Vite degli Arcadi Illustri*. But a more valuable though less beautiful edition, from which all the subsequent editions have been taken, is that of Venice, 1762, in two volumes 8vo; the first of which contains the *Poesie Toscane*, and the second the Latin verses of the same author, there for the first time collected from the different publications in which they had been previously scattered. There are subjoined some pieces in prose of inferior interest, if we except a literary correspondence of Filicaja with Francesco Redi, Menzini, and Gori, who shared with him the glory of having, in a corrupt age, remained faithful to the principles of good taste and sound literature. The *canzoni*, to which we have above referred, are perhaps the most remarkable compositions in this collection; but some of the other pieces are not inferior to these either in the dignity of the subject or the majesty and force of the style; and several of his *Sonnets* are worthy of these beautiful odes. Is there an Italian heart that can be insensible to the deep patriotic feeling, expressed with such a mournful and affecting sublimity, in the well-known sonnet, commencing

> Italia, Italia, O tu cui feo la sorte
> Dono infelice di bellezza, &c.;

one of the most perfect compositions of the kind in existence, and which, though it consists of only fourteen verses, will sustain a comparison with the most celebrated lyrical effusions, ancient or modern? We subjoin a happy translation.

> "Italia! thou to whom in evil hour
> The fatal boon of beauty nature gave,
> Yet on thy front the sentence did engrave,
> That ceaseless wo should be thy only dower!
> Ah! were that beauty less, or more thy power!
> That he who now compels thee to his arms
> Might gaze with cold indifference on thy charms,
> Or tremble at thine eye's indignant lower;
> Thou shouldst not then behold in glittering line
> From the high Alps embattled throngs descend,
> And Gallic foes pollute thy Po's clear wave;
> Nor, whilst encompassed close by spears not thine,
> Shouldst thou by foreign hands thy rights defend,
> Conquering or conquered, evermore a slave."

FILIGREE or FILLAGREE (Ital. *filigrano*; Lat. *filum* a thread, and *granum* a grain); a very delicate kind of ornamental work in gold or silver, wrought in the manner of little threads, or threads and grains intermixed. Filigree work is of Eastern origin, and was first introduced into Europe by the Italians. In Sumatra, manufactures of this kind have been carried to the highest degree of perfection, and yet the tools employed are exceedingly coarse and clumsy. These are generally rudely and inartificially formed from any piece of old iron. A piece of iron hoop suffices for making the wire-drawing instrument; an old hammer head, stuck in a block, serves as an anvil; and two old nails, tied together at one end, will suffice for a pair of compasses. The gold is melted in a piece of *preeoo* or earthen rice-pot, or sometimes in a crucible of ordinary clay. In general no bellows are used, but the fire is blown with the mouth, through a joint of bamboo; and if the quantity of metal to be melted is considerable, three or four persons sit round the furnace, which is an old broken quallee or iron pot, and blow together. At Padang, where the manufacture is most considerable, they have adopted the Chinese bellows. The method of drawing the wire differs but little from that which is used by European workmen. When drawn to a sufficient fineness, it is flattened by beating it on the anvil; and when flattened, a twist is given to it by rubbing it on a block of wood with a flat stick. After twisting they again beat it upon the anvil, and thus it becomes flattened wire with indented edges. The end of the wire is folded down with a pair of pincers, and thus is formed a leaf, or element of a flower, which is cut off. The end is again folded and cut off, till they have a sufficient number of leaves, which are laid on singly. Patterns of the flowers or foliage, in which there is seldom much variety, are prepared on paper of the size of the gold plate on which the filigree is to be laid. According to these, they begin to dispose on the plate the larger compartments of the foliage; for which they use plain flattened wire of a larger size, and fill it up with the leaves before mentioned. In order to fix the work, they employ a gelatinous substance made of the berry called *boca sago*, ground to a pulp on a rough stone. After the leaves have been all placed in order, and stuck on bit by bit, a solder is prepared of gold filings and borax moistened with water, which is strewed over the plate, when it is put in the fire for a short time, and the whole becomes united. This kind of work on a gold plate is called *carrang papan;* but when the work is open, it is called *carrang trouse*. In executing the latter, the foliage is laid out upon a card, or soft kind of wood, and stuck on, as before described, with the sago berry; and the work, when finished, being strewed over with the solder, is put into the fire, when the card or soft wood burning away, the gold remains connected. If the piece be large it is soldered at several times. In the manufacture of badjoo buttons, they first make the lower part flat, and having a mould formed of a piece of buffalo's horn, indented to several sizes, each like one half of a bullet mould, they lay their work over one of these holes, and with a horn punch press it into the form of a button; after which they complete the upper part. When the filigree is finished they cleanse it by boiling it in water with common salt and alum, or sometimes lime juice; and in order to give it that fine purple colour which they called *sapo*, they boil it in water mixed with brimstone. The manner of making the little balls with which their works are sometimes ornamented, is simple. They take a piece of charcoal, and having cut it flat and smooth, make in it a small hole, which they fill with gold dust, and this being melted in the fire becomes a little ball. They are very inexpert at finishing and polishing the plain parts, hinges, screws, and the like, being in this as much excelled by the European artists as the latter fall short of them in the fineness and minuteness of the foliage. The Chinese also make filigree, mostly of silver, which looks elegant, but wants the extraordinary delicacy of the Malay work. The price of the workmanship depends upon the difficulty or uncommonness of the pattern. In some articles of usual demand it does not exceed one-third of the value of the gold, but in matters of fancy it is generally equal to that of the metal.

FILIPPO D'ARGIRO, SAN, the ancient *Agyrium*, a town in the province of Catania, Sicily, situated on the summit of a lofty isolated hill near the centre of the island, and 32 miles W.N.W. of Catania. It has numerous churches and convents, and the vicinity is noted for producing the best saffron in Sicily. Agyrium was the birthplace of Diodorus Siculus. Pop. 7000.

FILLET, *in Carpentry*, is applied to a small piece to which a board, joist, quarter, &c. is nailed. *In architecture* fillet is of very frequent occurrence, and is applied to a flat rectangular moulding. It divides or terminates other mouldings, as in the cavetto surmounted with a fillet; in

Filter. the fluting of columns which are divided by a fillet; and in entablatures.

FILTER, an instrument or apparatus contrived for clearing liquids from any impurities mechanically combined with them. Filters are of various kinds, according to the nature of the liquor requiring to be clarified; but they all act on the same general principle, namely, straining the liquor by passing it through earth or other porous material; the process being thus exactly analogous to that of sifting, as used for powder or other dry substances. The operation of filtering is extensively used in chemistry and the arts, and also in purifying water for domestic purposes, and for the use of ships in long voyages; and hence the construction of artificial filters on a large scale for the supply of towns and cities with pure water becomes a very nice and difficult operation, and now forms an important branch of civil engineering. The pureness of spring water arises entirely from a process of filtration. Such water generally issues from a considerable depth beneath the surface of the ground, as is evident from the force with which it is discharged, and the equable temperature which it preserves throughout the year, being cool in summer, and in winter never freezing. Hence, in its course from the surface downwards, it must pass through a variety of soils, subsoils, and porous rocky strata; and it is by the perfect straining which it receives in percolating through such vast masses of filtering materials as must occur in the bowels of the earth, that it comes out at last with that admirable purity and transparency which we observe. But notwithstanding of this, spring water contracts, often among the rocks and minerals with which it comes in contact, various impurities, which become chemically dissolved in it, and from which it cannot be freed by filtration or any other mechanical process. It becomes often, therefore, unfit on this account for domestic use or the purposes of the arts, and is rarely equal, and never superior, to rain or river water properly filtered. The great importance of this operation, therefore, is evident, more especially from the frequent and serious failures which have taken place. But it may be better to defer the consideration of this branch of the subject till it can be resumed along with other hydraulic operations. See WATER-WORKS.

Water filters for domestic use. On a smaller scale, for domestic use, water filters have at different times been brought forward, and for many of them patents taken out. But as they are all very similar in principle, and none appears greatly distinguished above the rest, it is unnecessary to enter into a minute description of them. They are all liable to the objection of clogging up, and getting foul in the course of time. But if regularly cleaned, any of them will answer the purpose sufficiently well, the process of filtration being so simple and so easily effected. Several ingenious plans have been proposed for self-cleaning filters; the water, for instance, being made to ascend, or to pass alternately in opposite directions, and thus carry off the impurities by the process itself. But as none of these have succeeded completely, it will be found most convenient in small filters to clean them regularly; and those are therefore to be preferred which afford the means of doing this most conveniently.

Filtering materials. In these filters the filtering material generally used is gravel, sand, porous stone, or unglazed earthenware. Charcoal is sometimes added, but this is more for its antiseptic and purifying quality, and is only necessary in the case of fetid or very impure water. Gravel, though the best of all materials on a large scale, is rather coarse in itself for small filters. But where it occurs in nature in very thick beds, the large mass of material makes up for the coarseness of the grain; and many instances occur where springs from this source are scarcely inferior in purity to distilled water. But in small filters it requires a bed of sand above it to detain the impurities. Sand is perhaps, after all, the best filtering material; it should, however, be clean sea or river sand, with no tincture of iron; this last is indicated by its reddish colour, which, if deep, will communicate an iron taint to the water, a circumstance harmless enough in itself for most domestic uses, but very prejudicial for the purposes of bleaching, paper-making, &c. in the arts.

Sand and gravel filters. In filters constructed with gravel or sand, all the apparatus that is necessary is a vessel to contain the filtering material, with a space above for holding a quantity of the water to be filtered, and a vessel below for receiving the filtered water. A simple and convenient apparatus of this kind was contrived by Messrs Hearman and Dearn, potters, Redriff, described in Nicholson's *Journal*, vol. viii., and represented in Plate CCLVIII. fig. 1, which exhibits the whole apparatus, and shows, in fig. 2, a shaded section. A is a vessel of stone-ware perforated with holes, *m*, at bottom, upon which coarse gravel, *h*, is laid, and on that again a stratum of fine gravel, and, lastly, fine sand, *g*. Or, otherwise, the bottom may be covered with a coarse cloth, which will render the graduated fineness of the gravel and sand less necessary. Upon the top of the sand is laid a perforated and loaded board or plate of earthenware, to prevent the sand from being disturbed when the water is poured in. B is a lower vessel, into which the filtered water from A drops, together with any sand that may escape from above. The clear water flows out through the neck *ac* into the vessel *d* for use.

On this plan an excellent filtering apparatus may be constructed at little expense, and in various ways, according to the means or conveniencies most readily at hand; and the sand and gravel possess a decided advantage over filtering stones or other materials, from the great facility of cleaning, the latter being liable, from long use and the impurities lodging in their pores, to give the water an unpleasant taint.

A very simple arrangement in the above plan is to have a cylindrical jar of earthenware, as at fig. 5, with two partitions or false bottoms, dividing the height into three equal portions, the partitions resting each on a shoulder formed all round on the jar, or otherwise supported; the middle division for the filtering material, the upper one for the water to be filtered, and the lower one for containing the filtered water, with a stop-cock for drawing it off at pleasure, and a vent or opening at the top for the admission and discharge of air. The stop-cock must be placed three or four inches from the bottom, to allow full space for any sand or other material to deposit in the bottom; and the air vent must be carried up by a small pipe to the top of the jar, to prevent the water ever rising and overflowing by it. The partitions are made of earthenware, with a number of small holes to allow the water to descend. If sand only is used, it will be necessary to spread a layer or two of cloth under it, to prevent the sand getting through the openings. But if gravel can be had, it will be better to lay a bed of this, of two inches or more in thickness, on the bottom, and the sand above it. After the sand is filled in to the height of the upper partition, this is placed on as a cover, which having also a number of small openings in it, the water flows from the upper division downwards. The cover should press on the top of the sand, in order to prevent its being disturbed by the entrance of the water, or a layer of gravel should be placed on the top of the sand. If a layer or two of cloth be laid over the partition, it will serve to detain some of the impurities; and being frequently washed, it will make the filter continue longer clean. In order to clean this filter it is only necessary to remove the upper partition, take out the upper stratum of sand to the depth of two or three inches, wash it thoroughly, and replace it; or, if sand can be had readily, let the whole be replaced with a fresh quantity, clean and pure. This is,

on the whole, a very simple, perfect, economical, and convenient filter. It may be constructed of wood or other convenient material, and is both very easily formed, and easily kept clean and in order; and by varying the thickness of the bed of sand, it can be adapted to the exact degree of filtration required. The vessel also admits of any ornamental shape which taste may direct; and several elegant figures of this kind, contrived by the manufacturers, are shown at the bottom of the plate. If the lower division also were left unglazed and porous, an evaporation would go on from the outside, so that in summer it would act as a cooler as well as a filterer. Should much sediment be found collecting in the lower vessel, perhaps it would be better to place the whole apparatus upon a second jar, so wide as to allow the first to stand over it, and having a pipe in the bottom rising nearly to the top of the vessel, and open at the top. The filtered water would flow over this, and descend into the lower vessel, which being detached, could always be kept perfectly clean in the bottom. The upper end of the pipe should be covered with a fold or two of cloth. An ingenious plan, introduced by Mr Parkes, chemist, for drawing off the water in the reservoir of a filtering or purifying apparatus, though applied rather on a larger scale, might often be used with advantage in smaller filters, such as those for bleachers, paper-makers, and others. It is represented at fig. 6, and consists in connecting the stop-cock for the discharge of the water with a pipe and flexible joint terminating in a rose-head and floating ball, which keeps the head always immersed a little under water, and thus discharges it from near the surface, although the level of the water may vary considerably. The water here is also let in, not directly into the reservoir, but by an upright pipe having a funnel at the top, and descending to near the bottom, which causes the water to enter below, where it must deposit any impurity before this can rise to the surface.

Filtering by descent and ascent.

In the sand and gravel filters here described, the water descends during the whole of the process, and this causes a slight tendency to carry minute particles of sand or other impurities along with it. To remedy this defect, various plans have been proposed for making the water, after descending, again ascend; and this plan certainly possesses advantages, and is a decided improvement on the other. A very neat contrivance of this kind is that proposed by Professor Parrot of Paris, in Nicholson's *Journal*, and is represented at fig. 3.

By Professor Parrot.

It consists simply of an inverted siphon, which could be easily made of lead, having the bend filled with sand, and being covered on the top with gravel in each branch. The water entering the longer branch from a reservoir, passes through the sand, and rising up, is discharged at the other end, which should be three inches below the level of the first. When the section of the tube is four inches by two, and eighteen inches the length of sand, it was calculated that six Paris pints of pure water would be passed in an hour.

By Sir H. Englefield.

Another plan, proposed by Sir Henry Englefield, in the same work, is shown at fig. 4. It consists of a conical vessel placed within the one containing the sand, and allowing the water to descend on the inner vessel, and ascend again in the outer one.

But the simplest mode of effecting the ascent of the water is merely to divide the jar or filtering vessel by a vertical partition, open at the bottom. The water being then poured into the one side, descends to the bottom, passes under the partition into the other side, and ascends to the same level at which it entered, and can then be drawn off by a stop-cock or other means at pleasure. In that case a single vessel only is wanted, and contains in itself the means of holding separately the filtering material, the water to be filtered, and the water after filtration. Upon the whole, this appears by far the simplest, most perfect, most economical, and most convenient filter of this, or perhaps of any kind, that can be contrived. All that is necessary is to have a pretty deep vessel of earthenware, wood, or other material; a tub or barrel will answer perfectly. Put a vertical partition in the middle, reaching nearly to the bottom, fill it half or three fourths full of sand, with a layer of gravel on the top, and it is ready for use. It may be found convenient, to prevent the gravel being disturbed, to place a cover over it, with holes. The water may either be drawn directly from the pure side with jugs, or let off by a stop-cock. Instead of sand and gravel, some have proposed to use charcoal, either by itself or in combination with the others; and an apparatus of this kind was contrived by Mr John Isaak Hawkins. It is only, however, when the water has an impure taint, which cannot be removed by sand, that the charcoal should be resorted to, as it is more expensive, and more difficult to be cleaned. In long voyages, however, charcoal, as proposed by Hawkins, may, in conjunction with sand, be found very useful.

Charcoal filter by Mr Hawkins.

Filtering by ascent alone.

Instead of the water descending and then ascending, several ingenious methods have been contrived where the water only ascends through the filter, being let in below, and forced upwards by the pressure of an external head of water. The advantage of this is, that the filter can be cleaned by letting the water return and run out at the place where it usually enters. These plans, however, on a small scale, are hardly ever found to supersede cleaning. On this principle was the patent granted in 1791 to Mr Peacock, which he intended for small filters as well as those on a large scale. His apparatus consisted of a vessel of wood, lead, or other materials, of any shape or dimensions required, divided near the bottom by a horizontal grate or partition, upon which the filtering medium was spread in layers, beginning with the coarsest and ending with the fine. The lower division had a communication with a more elevated reservoir, from which the water flowed, and rose through the filtering bed. This consisted of gravel, sand, broken and pulverized glass or pottery, all well washed and sifted with sieves. On a similar principle Mr Bramah had a patent for various modes of conveying and drawing off beer and other liquors, in which he describes a filtering apparatus which he proposed to place in the pipes to conduct the liquor. This was a cylindrical vessel, made of copper tinned within, or of any other materials; the upper end was closed by a lid screwed on by a flange, and the lower end terminated in a cone; a pipe was inserted into the vessel near the lower part, to introduce the liquor; and from near the upper end a similar pipe proceeded to convey it away. Between these two was fixed the filtering floor, consisting of flannel, sand in bags, sponges or other similar substances, which were spread upon a horizontal plate pierced full of small holes, and fixed in the cylinder above the filtering substance; and another similar plate was fixed and screwed down to confine it. The liquor was introduced by the lower pipe by means of a pump or otherwise, and ascending through the filtering floor, passed off in a clarified state; the impurities which are separated collect in the conical bottom of the cylindrical vessel, whence they can be drawn by a cock. This contrivance is adapted to give a slight filtration to a great quantity of liquor, such as beer; and Mr Collier, in a patent for the purification of oils, claimed the principle of filtering *per ascensum* combined with hydrostatic pressure.

Mr Peacock.

Mr Bramah.

Mr Collier.

Filtering stones.

Such are the different contrivances for filtering water, where sand and gravel are the materials; but notwithstanding their simplicity, filters of porous stone are those which have hitherto been most generally in use. The

Filter.

stones are procured from beds of sandstone, and sometimes a kind of limestone. They are found in Northamptonshire, Derbyshire, and other parts of England, and are often imported from the island of Teneriffe. The construction of the filter is extremely simple. A thick bowl or basin is formed of the stone, and mounted in a frame. The foul water, being poured into the basin, passes slowly through the substance of the stone, and drops into a receptacle below, in a perfectly transparent state. When the water is foul, a small quantity of mud or slime is found to collect at the bottom of the basin, and must occasionally be cleared out; but in the course of time the more minute impurities will insinuate themselves into the pores of the stone, and at last clog up the passage of the water. This is remedied by chipping away the interior surface of the stone one half or three fourths of an inch, because the impurities do not penetrate deeper into the stone. This will restore its action for a long time.

The basin shape used in these filters is obviously not the most proper, as it leaves an unequal thickness in the bottom for the water to penetrate, and also the pressure of the fluid is unequal. The bottom should be flat and of equal thickness, and in fact it would be much better not to make the stone a reservoir at all; but to use a filtering vessel such as above described, substituting for the sand and gravel a plate of the filtering-stone, of such thickness as may be found best adapted for the nature of the water. If a thin plate also were placed on the top of a thick one, it might then be removed without any trouble when it got foul, and replaced by another, without disturbing the lower mass; or several plates could be laid one above another till the requisite thickness for filtering were obtained.

Filtering upwards.

Instead of pouring the water into the basin and allowing it to filter downwards, the water may be contained in a vessel in which the basin is nearly immersed; and in this way the water will filter partly laterally, but chiefly *per ascensum*, and leave much of its deposit behind, so as to enable the stone to continue longer clean. A filter on this plan was contrived by Mr Moult, and is described in the Transactions of the Society of Arts. The filtered water runs in and fills the basin, from which it can be taken out or let off by a pipe. This principle was also proposed by Mr Collier, and it possesses all the advantages we have already described in filtering upwards with sand; and if it were used with plates of the stone instead of a basin, it would be still more effectual.

Anglesea earthenware filters.

The unglazed earthenware for filtering has been introduced as a substitute for the filtering stones. It is made of different compositions of pottery. The original patent was granted to Mrs Johanna Hempel, potter, Chelsea, in the year 1790. The proportions were four out of nine of tobacco-pipe clay, and five out of nine of coarse sea, river, or pit sand. This was intended for basins not exceeding one gallon. For larger capacities it is liable to fly or crack in the fire. A second composition, therefore, consisted of equal parts of tobacco-pipe clay and sea or river sand; or if this was found insufficient to prevent the cracking, three parts tobacco-pipe clay, one of Stourbridge clay, or clay from the surface of the coal mines, one of Windsor loam, or other loam of equal quality, and four of coarse river or sea sand; or four parts of tobacco-pipe clay, three of sand, and one of the burnt ground clay of which crucibles are made. The above ingredients are brought to the proper basin or bowl shape on the wheel, and are then hardened in the furnace like other pottery ware. The same objection, however, applies here to the basin shape as to the stones; in fact, it would be better to have this composition formed into plates of different thickness, which could then be used, one or more in number, in the filtering vessels, instead of sand or stone; one could be taken out when foul, and another put in, with the utmost facility; and this would certainly be attaining the perfection of a filtering apparatus.

Another still simpler plan would be to have one filtering vessel, with a vertical partition of the porous ware reaching to the bottom. The one half of the vessel would then be filled with the impure and the other with the pure water; and if several of these plates were at hand, one partition could be taken out when foul, and another inserted in its place, or there might be two porous partitions, and a solid one between them. The one would then ascend and run over the top of the solid partition, and again descend and pass through the second porous partition, which would therefore hardly ever require renewal.

A filter, the invention of Mr Robins of London, and for which he took out a patent, has been much recommended to the public. The external appearance is varied according to taste; and figs. 13, 14, 15, already referred to, represent some of the neatest and most elegant patterns. We are not acquainted with the interior construction, but understand it consists of various strata of filtering material, such as we have above described, arranged so as to act with peculiar efficacy. At the top there is a sponge neatly inserted into a recess above the upper partition, which is a very judicious and useful mode of detaining any impurities, and preventing them from getting into the filterer, the sponge being easily taken out and washed from time to time. The patentee, however, claims far higher powers for his invention than that of mere filtration. He states that the interior process involves a *voltaic* action, which decomposes soluble substances, and renders the water equal in purity to distilled water. We confess we have great doubts in regard to this, and think it irreconcilable with any idea of voltaic or chemical action with which we are acquainted. Still we have no doubt, from the various testimonials brought forward, that the filter is a good one. Fig. 14 is about three feet high, and one and a half broad, and is calculated to filter fifty gallons a day; the others in proportion.[1]

From the great success with which water has been purified by filtration, attempts have been made to purify oils in the same manner; and an ingenious apparatus for this purpose was contrived, and a patent taken out, by Mr Joshua Collier, applicable also to water and other liquids, and of which an account will be found in the *Repertory of Arts*, vol. x. But in oils there is generally so many impurities, chemically or otherwise united, that filtration can do little for their purification. Charcoal is the substance chiefly employed. A filtering machine contrived by Mr Innes of Edinburgh is said to answer well for oils and other fluids. By it the fluid is forced through the pores of wood by the action of a forcing-pump. Such a degree of pressure is unnecessary for water; but for oil, quicksilver, and other valuable fluids, it appears certainly well adapted.

Filtration in chemistry.

Filtration is much used in chemical processes. The materials employed are unsized paper, cloth, flannel, tow, sponge, sand, pulverized glass, flints, porous stones, earthenware, &c. In fig. 12 is represented a neat little filtering apparatus constructed by Mr Parkes; and the following remarks and directions are taken from Mr Faraday's excellent work on Chemical Manipulation. "Of the above substances, the first is almost exclusively in use at the laboratory, a few of the others now and then being resorted to only on particular occasions.

"Funnels are continually necessary to support the paper through which filtration is to take place. The ordinary funnels required in the laboratory for the passage of fluids answer the purpose very well, but they are of use for supporting filters, when, from their necks being broken off, they are otherwise unserviceable. They may be either of glass or good Wedgewood or other earthenware; those

[1] Besides those already mentioned, there are many excellent filters in common use, but their construction offers nothing to call for a special notice.

of glass are to be preferred, because the progress of the filtration and the state of the filter can be better ascertained in them. Metal funnels should not be allowed in the laboratory.

"The funnels containing filters may be frequently supported by the glass or jar intended to receive the filtered fluid, and at other times by the rings of retort stands. But notwithstanding these facilities, so frequently is the operation required, that a laboratory should be supplied with at least one filtering stand of considerable size. The end of such a stand is represented in fig. 7.

"It is no easy matter for the chemist to obtain unobjectionable filtering paper. It is amongst the thinner varieties of unsized paper, or white blotting-paper, that the chemist will probably find the kind best suited to his purpose.

"Filtering paper should be cut ready for use into different sizes. The simplest filter is made by folding the paper twice in opposite directions, so as to bring the four corners together, and by opening one corner from the other three, so as to produce an irregular conical cavity, as in fig. 8. Such a filter being put into a funnel and then filled with liquid, will immediately permit its passage; but from the similarity of form between the filter and the funnel, and the close adhesion of the former to the latter over by far the greater part of its surface, considerable obstruction is opposed to the passage of the fluid. Much the best expedient for facilitating its passage is so to fold the filter that ribs may exist in the paper itself. For this purpose, the paper is first to be doubled, and in this state is again to be folded in half, each half folded into quarters, and each quarter into eighths, the folds being all on the same side, and radiating at equal distances from the middle of the folded edge to the other edges. Fig. 9 represents the doubled paper thus divided into eight parts. Each eighth is now to be divided into half by folds in the opposite direction, but in lines still originating at the same centre, which makes the doubled piece resemble a child's paper fan, both when closed and when a little open: it is represented by fig. 10. Whilst in this state, the projecting corners should be taken off by a knife; folding the whole up tight like a closed fan, and making the section at about *a*. Having opened it sufficiently to separate the cut edges from each other, it will be found that the paper is equally divided into parts forming alternate external and re-entering angles, except at the two edges *bb*, where two external angles come together. Here the intervening portion of paper between the two contiguous external angles should be folded, by bringing the latter together, and creasing the paper down, so as to form a re-entering angle between them: this should be done at both places. Its appearance when perfectly formed is represented at fig. 11.

FIN. See Ichthyology; and Mammalia, § *Cetacea*.

FINAL CAUSE. See vol. iii., p. 540.

FINALE, a seaport-town of the kingdom of Sardinia, on the Gulf of Genoa, 10 miles N.N.E. of Albenga. It consists of two parts about a mile distant from each other—the one Finale Borgo standing on a hill, the other Finale Marino on the shore. It has some trade in fruits, but the harbour is small and insecure. In the vicinity are numerous ruined forts. Pop. 5000. There is another Finale in the duchy of Modena, on the Panaro, 10 miles from its junction with the Po. It has manufactures of silk and woollen fabrics, and some trade in corn, wine, and hemp. Pop. 7000.

FINANCES, in *Political Economy*, the revenues of a king or state; analogous to the treasury or exchequer of the English, and the *fiscus* of the Romans. The word is derived from the German *finantz*. See Taxation.

FINCH, Heneage, first Earl of Nottingham, and lord high chancellor of England, was the son of Sir Heneage Finch, recorder of London, and born in December 1621. He received his education at Westminster School, and at Christ-Church College, Oxford, of which he was a gentleman commoner; and he studied law in the Inner Temple, where, by his talents and diligence, he became remarkable for great legal acquirements. On the restoration of Charles II. he was made solicitor-general, and created a baronet. He was also appointed reader of the Inner Temple, and chose as his subject the statute of the 39th Elizabeth, concerning the payment and recovery of debts of the crown, which he treated with great force of reason and depth of legal erudition. As solicitor-general, he took an active part in the trials of the regicides; and in 1661 he was chosen member of parliament for the university of Oxford, by the recommendation of Lord Clarendon. In 1667, when Lord Clarendon was impeached for certain alleged high crimes and misdemeanours, Sir Heneage defended him against the charges preferred by his enemies. In 1670 he was appointed attorney-general, and, some years afterwards, lord keeper. He was then raised to the peerage by the style and title of Baron Finch of Daventry, in the county of Northampton; and, in 1675, appointed lord high chancellor of England. He officiated as high steward at the trial of Lord Stafford, who, in the madness of that time, was found guilty of high treason by his peers, on a charge of being concerned in the Popish plot. In 1681 he was created Earl of Nottingham, and died the following year, at his house in Queen Street, Lincoln's-Inn-Fields. Lord Nottingham was distinguished for both sagacity and eloquence; and, though he lived in times when it was difficult to pursue a steady and consistent course, he conducted himself in such a manner as to retain the favour of the court without forfeiting the approbation of the people. "He was a person," says Mr Justice Blackstone, "of the greatest abilities, and most incorrupted integrity; a thorough master and zealous defender of the laws and constitution of his country; and endued with a pervading genius that enabled him to discover and pursue the true spirit of justice, notwithstanding the embarrassments raised by the narrow and technical notions which then prevailed in the courts of law, and the imperfect ideas of redress which had possessed the courts of equity."

In the name of the Earl of Nottingham have been published, 1. Several Speeches and Discourses on the Trials of the Regicides; 2. Speeches Delivered in both Houses of Parliament; 3. Speech at the Sentence of William Viscount Stafford, 7th December 1680; 4. Answers to His Majesty's Command upon several Addresses Presented to His Majesty at Hampton Court, 19th May 1681; 5. The Arguments upon which he made the Decree in the Cause between the Honourable Charles Howard, plaintiff, Henry Duke of Norfolk, Henry Lord Mowbray, his son, Henry Marquis of Dorchester, and Richard Marriot, Esq., defendants, folio; 6. An Argument on the Claim of the Crown to Pardon on Impeachment, folio. He also left in manuscript *Chancery Reports*, and notes on Coke's *Institute*. (J. B—E.)

Finch. See *Fringilla* in index to Ornithology.

FINDHORN, a river of Scotland. See Morayshire.

FINE, in *Law*, has different applications. Until recently it was a very usual species of assurance of lands or tenements, or of anything inheritable, and was so called because it put an *end* to all suits and controversies concerning the same matter. It bound not only the granter himself and his heirs, but also all mankind, whether concerned in the transfer or not, if they failed to put in their claims within the time allotted by law. By the 3d and 4th Will. IV., cap. 74, no fine can be levied after 31st Dec. 1833.

Fine also signifies a sum of money paid for entering lands or tenements let by lease; and sometimes a pecuniary mulct

for an offence committed against the king and his laws, or against the lord of the manor.

FINE ARTS. See ARTS, and EXHIBITION.

FINGAL, king of Morven. See OSSIAN.

FINGAL'S CAVE. See STAFFA.

FINIAL. See glossary to ARCHITECTURE.

FINISTERE, or FINISTERRE, the most western of the French departments, and forming part of the old province of Bretagne, is bounded on the N.W. and S. by the ocean, while on the E. it has the departments of Cotes-du-Nord and Morbihan. It extends from N. Lat. 47. 44. to 48. 47., and from W. Long. 3. 22. to 4. 50.; being 78 miles in length from N. to S. by 63 in width, and having an area of 666,705 hectares, or 2574 square miles. Two chains of hills run nearly parallel from E. to W. through this department, and divide it into three zones of nearly equal extent, conveying the waters in three different directions. North of the Arrez, or more northern of the two chains, the waters of the Douron, Jarleuc, Penzé, Flèche, &c., flow northward to the sea. South of the Noires range the Odet, Aven, Ioste, and Elle, flow southward; while the region inclosed by the two chains having a declination westward, the waters of the Aulne and the Elorn flow into the Brest roads. The rivers are all small, and none of the hills attain a height of 900 feet. The coasts are generally steep and rocky, and indented with numerous bays and inlets, affording some excellent harbours, the principal being those of Brest, Morlaix, Landernau, Quimper, and Douarnenez. The only navigable rivers are the Aulne, Elorn, and Odet. Off the coast lie a number of islands and rocky islets, the principal of which are Ushant and Bas. The climate is temperate, but rather humid; the prevailing winds are the W., S.W., and N.W. Of the 1,647,521 acres contained in this department, 675,142 are arable, 663,678 heath and waste land, 81,055 woods and forests, 101,095 meadow land, and 24,797 gardens, orchards, &c. Though so small a portion of the land is under cultivation, yet the produce of corn is more than sufficient for the population, and would be still greater were more scientific methods pursued in its cultivation. The chief crops are oats, rye, wheat, and barley; flax, hemp, and pulse, of good quality, are also produced. The pasturage being good, considerable attention is given to the rearing of cattle; and the fisheries of the coast, particularly the pilchard fishery, employ a great many hands, and render this department an excellent nursery of seamen for the French navy. Finistère is rich in minerals—iron, coal, lead, bismuth, and zinc mines, are worked; as well as quarries of granite, slate, marble, and porphyry. The lead mines of Poullaouen and Huélgoët are among the largest in France, and the ore extracted yields a considerable quantity of silver. The manufactures are linens, woollens, sailcloth, ropes, paper, leather, earthenware, soda, soap, candles, sugar, &c. Ship-building is carried on at Brest and other of the seaports. Finistere is divided into 5 arrondissements as follows:—

Arrondissements.	Cantons.	Communes.	Pop. in 1851.
Quimper	9	62	117,489
Brest	12	83	204,765
Châteaulin	7	59	105,658
Morlaix	10	58	142,863
Quimperlé	5	20	46,935
Total	43	282	617,710

FINLAND, called by the natives *Suomemna*, the Region of Lakes or Swamps, is a government of Russia, comprising, besides the old Swedish province of Finland, the two Lapmarks of Kami and Torneå, and the district of Wiborg. It lies between N. Lat. 59. 50. and 70. 6., and E. Long. 20. 30. and 32. 45., being bounded on the N. by Norwegian Finmark, by Sweden W. and the Gulf of Bothnia, S. by the Gulf of Finland, and E. by the governments of St Petersburg, Olonetz, and Archangel. It is about 730 miles in length from N. to S., with an average breadth of about 185 miles. The sea-coast of Finland throughout its entire extent presents the same succession of fiords and rocky headlands as characterize the whole seaward frontier of Sweden and Norway. The fiords of Finland, however, are far more limited than those to the west of the Gulf of Bothnia, and seldom exceed a few miles in extent, although their mouths contain an equal number of islands, some of which, as the isles of Sveaborg, have been converted into fortresses of great strength. The coasts of the Bothnian and Finland Gulfs are thickly strewn with rocks of granite and limestone, presenting in some places a labyrinthine archipelago of little islands, rendering the navigation extremely dangerous. The greater portion of the interior is a vast table-land averaging in height from 400 to 600 feet, and interspersed with hills of no great elevation. In the north, however, are the Manselka Mountains, which attain a height of nearly 4000 feet, and stretch southward, though with several interruptions, until they terminate in lofty cliffs on the Gulf of Bothnia. The great mass of the mountains is composed of red granite, and vast quantities of the same rock lie in boulders on the lower grounds, and prove a very serious obstacle to their cultivation. Many of the heights are bare, but the greater part of them being of moderate elevation are covered with forests chiefly of pine; and in combination with the vast number of lakes inclosed by their bases, often form very romantic scenery. The extensive forests are sometimes devastated by the tempests of winter, which seem to find access to their very centres in tornadoes, tearing up by the roots or bending and snapping the largest pines. Frequently also ravages are committed in them by conflagrations occasioned often through the carelessness of the peasants. The interior of Finland is also intersected and broken up by a vast number of lakes, throwing out winding arms and branches in all directions, which, while they offer the greatest facilities for inland navigation, render land travelling circuitous and dangerous. Many of the high roads pass over islands on these lakes, the natural strength of whose situation has been taken advantage of, to cover them with batteries; and some of them, as at Wiborg and Nÿslot, are considered impregnable, save to fraud or famine. The principal of these lakes are Ladoga, the greater portion of which belongs to this government; Lake Saima, which is crowded with islands and discharges its superfluous waters in a series of cataracts into Lake Ladoga, but which is now connected by means of a canal with the Gulf of Finland near Wiborg; and Lake Enara in the extreme north, covering above 1000 square miles, and having its outlet in the Frozen Ocean. The chief rivers are the Uleå, which is navigated by trading vessels though its stream is very rapid; the Cano which passes Biörneborg; the Aurajoki which at Abo is about 100 yards broad; the Kymen which flows into the middle of the Gulf of Finland; and the Torneå which discharges itself at the northern extremity of the Gulf of Bothnia, and forms the present boundary between Sweden and Russia. The climate varies much according to the locality. In Lapmark, in the north, it is polar somewhat modified, and the sun disappears during December and January. Further south at Uleåborg, winter begins in October and continues to May, to which month spring is limited. Summer commences in June and lasts three months, which are generally so hot and dry that the crops, particularly where the soil is of a sandy nature, often suffer from drought. The autumn, like the spring, is confined to one month, and may be said to commence and terminate in September. Even in summer the nights are cold, particularly about the middle of August. During summer, however, the progress of vegetation is remarkably rapid; and there have been instances of grain being sown and reaped in six weeks. In the more southern parts the climate is less severe; the winter being of five or six

Finland.

months' duration. Dense fogs are frequent, and heavy rains take place in autumn. The soil is for the most part stony or sandy; but notwithstanding this it is much more productive then the opposite part of the Scandinavian peninsula, and when in the possession of Sweden it was termed the granary of that country. The principal crops are barley and rye, but owing to the nature of the surface and climate a large portion of the land is fit only for pasture. In the north, where vegetation is almost confined to the growth of moss and lichen, other domestic animals are superseded by the reindeer, of which great herds are kept. In addition to timber (chiefly fir), large quantities of potash, pitch, and rosin are obtained, and form the principal articles of export. The mineral productions are chiefly confined to iron, lead, sulphur, slate, and granite. The first is only wrought to a limited extent for the supply of a few furnaces; wrought iron being now principally imported from Sweden. A great number of excellent granite quarries have been opened, chiefly on the borders of the lakes or sea-coasts to secure the advantage of water carriage. From these are obtained blocks of extraordinary magnitude and beauty, which are employed for architectural and artistic purposes. One of the finest specimens is the monolith obelisk recently erected in St Petersburg to the Emperor Alexander. In its rough state it was 12 feet in diameter, and 80 feet in length. The manufactures of Finland are insignificant. Agriculture, the rearing of cattle, and fishing are the principal occupations of the inhabitants. The coasts present many good harbours, but on account of the long winter they cannot be extensively used. In winter sledges afford an easy and rapid communication with different parts, and even with Sweden across the Gulf of Bothnia. In March 1809, Barclay de Tolly crossed over with a division of the Russian army from Vasa to Umeå in Sweden.

From official documents the returns of the trade of Finland for the year 1848 were in silver rubles of the value of about 3s. 2d., as follows:—

EXPORTS.

To Sweden and Norway	197,942
To other countries	1,946,994
Export duty on the same	38,704
Total	2,183,640

IMPORTS.

From Sweden and Norway	430,366
From other countries	3,123,590
	3,553,956
Deduct import duty thereon	893,500
	2,660,456

Showing an excess in the imports over the exports of 476,816 rubles, which, however, was in part covered by the freight earned by the merchant shipping. The above statements indicate a falling off as compared with former years in the export trade to Norway and Sweden. To these two countries the leading articles of export and their value were—fish 23,569 rubles; hides 8616; beef 24,578; grain 15,083; tallow 30,809; tar 11,483; firewood 11,483. The imports were—books 16,200 rubles; fish 25,228; iron and steel 250,870; sugar 66,418; tobacco 4677; dye-woods and stuffs 23,990. The exports to other countries were also less than in former years; the chief articles were—potash 16,733 rubles; butter 183,409; tar 324,717; wood and timber 921,360. The chief imports from other countries were—medicines 20,914 rubles; cotton 138,318; arrack, rum, brandy, 169,794; coffee 597,708; fruits 106,042; dye-stuffs 134,550; yarn 349,933; iron and steel 89,709; salt 531,665; sugar 544,485; wine 140,528; manufactures wove 666,145.

In 1831 Finland was divided administratively into eight circles or *läns*, which are sub-divided into *fogderier* or districts, and *herads* or bailiwicks. There is a distinct establishment at St Petersburg for the government of this vast province. The governor-general, who resides at Helsingfors, has the superintendence of the military affairs. Finland has a diet composed of the four orders of the nobility, clergy, citizens, and peasantry, and a code of laws and judicial system similar to that of Sweden, but the diet is rarely convoked, except to consent to the imposition of fresh taxes, a senate more recently established having replaced it in the exercise of its functions. The regiments raised in Finland are not promiscuously intermixed with the general forces of the Russian empire; and their fleet, by far the best manned portion of the Russian navy, forms a distinct squadron under the Finnish flag. None but a native Finlander can hold any office of trust in the country. Almost all the inhabitants are Lutherans under the bishops of Abo and Borgo, except in the circle of Wiborg, where they belong to the Russian Church. Public education is in a very backward state. At Helsingfors is a university, transferred from Abo in 1828; and all the towns have schools, but there is a great deficiency of country schools. The majority of the inhabitants are Fins, who call themselves *Suomalans* or *Suomes*, but they are denominated Tschudes by the Russians. They are of middle height, robust, flat-faced, with prominent cheek-bones, light, reddish, or yellowish-brown hair, gray eyes, little beard, and a dull sallow complexion. They are courageous, hospitable, and honest, but obstinate in the extreme, indolent, dirty, and it is said revengeful. Their customs and habits have been handed down from time immemorial, and their costume forcibly bears out the supposition of their being of oriental origin. The peasants wear long loose robes of a coarse woollen manufacture, secured by a silken cincture like the *kummerbund* of the Mussulmans. The eight läns with their areas and populations are as follows, commencing from the south and east:—

	Area.	Population.
Wiborg	16,700	224,701
St Michael	9,271	135,231
Nÿland	5,376	149,714
Tavastehuus	7,112	132,586
Abo	10,626	250,238
Vasa	15,938	199,437
Kuopio	17,039	156,706
Uleåborg	63,415	125,114
Total	145,477	1,373,727

The chief towns of Finland are Helsingfors the present capital, Abo the former capital, Wiborg, Tavastehuus, Vasa, Uleåborg, and Torneå. The Fins were Pagans living under their own independent kings till the twelfth century, about the middle of which Finland was conquered by the Swedes, who introduced Christianity. The province of Wiborg was seized by Peter the Great in 1721, and the remainder of the country was annexed by conquest to the Russian dominions in 1809.—(*Athenæum*, 18th March 1854.)

Finland, Gulf of; Firdusi.

FINLAND, *Gulf of.* See BALTIC.

FIORENZUOLA, a town of Northern Italy, duchy of Parma, on the Emilian way, 18 miles W.N.W. of Parma. The town contains many remains of antiquity, and the sacristy of the collegiate church has some curious relics of ancient art. It is supposed to be the ancient *Fidentia;* and about eight miles to the south were discovered in 1761 the ruins of *Veleia*, buried in the fourth century by the fall of the mountain at the foot of which it was situated. Cardinal Alberoni was born at Fiorenzuola in 1664. Pop. 3000.

FIR. See PLANTING; TIMBER; STRENGTH OF MATERIALS.

FIRDUSI, or, as the name is variously written, FERDUSI or FERDOUSI, ABUL-CASIM MANSOUR, a celebrated Persian poet, was born at Shadab in Khorassan. The date of his birth is not very well known, but from the internal evidence of the *Shah Nameh* may be assigned approximately to the year 930. His father was a gardener in the service of

Fire, Nature of, || Greek Fire.

a wealthy Persian, and from the name of the spot which he cultivated (Firdus or Ferdus, *i. e.* Paradise) it is believed that the young poet derived his name. Firdusi had already passed the prime of life when he left his native village for the court of the Sultan Mahmoud, who at that time lived in the city of Ghazna. Chancing to fall upon an old history of Persia, he perused with the utmost eagerness the old legends of the early wars of that country; and by the advice of Mahmoud he began a complete poetical history of the Persian kings. For thirty years he laboured at this work, encouraged by the sultan, who promised him a thousand pieces of gold for every couplet. At the end of that period, however, he was doomed to be cruelly disappointed. Some of the courtiers had taken umbrage at the severity with which he satirized their intrigues, and had poisoned the mind of Mahmoud against him, so that instead of keeping his promise, that monarch rewarded the poet with silver pieces instead of gold. Enraged at this meanness, Ferdusi quitted the court, leaving behind him a manuscript which he requested should be read to the sultan the first time he felt himself exhausted with fatigue or out of temper. The document in question was a satire on his majesty, which so irritated the monarch, that he persecuted the poet during the remainder of his life, and compelled him to wander from country to country till his death. He first took refuge at Mazanderan. Driven thence he fled to Baghdad, the caliph of which city presented him with a reward equal to that which he ought to have received from the Sultan Mahmoud. But the emissaries of that potentate still continued to persecute him, till a pardon was with difficulty extorted from their master, and the ill-starred poet returned to his native town, where he died in 1020, in the eighty-ninth year of his age. Ferdusi's great work, the *Shah Nameh*, which is a history of the Persian monarchy from its foundation till the year 641 A.D., is of little value in an historical point of view, except in so far as it preserves many of the old traditions of the country. As a poem, however, it still holds a very high place in Oriental literature. This perpetuity of fame is due in an equal degree to the intrinsic poetical merits of the work and the purity of the Persian in which it is written. It is said that no work in the Persian language is so free from foreign admixture as the *Shah Nameh*. No complete copy of the work is known to exist. Several collations of numerous MSS. have been made, though unsuccessfully, with a view to making up a complete text. Of these may be mentioned that made by Dr Lumsden, of which only a part has been published; and that of Mr Macan, published at Calcutta in 1829, in 4 vols. 8vo. An abridgment of the *Shah Nameh* in prose and verse was published by Mr James Atkinson, London, 1833.

FIRE, NATURE OF. See HEAT.

Greek Fire, a kind of artificial or factitious fire, which is said to have been used with wonderful effect in the wars of the Christians and Saracens in the seventh century. Its ingredients are not known, the composition of it having been kept a profound secret; nor do the accounts that have come down to us admit of anything but conjecture as to its nature. From the descriptions of its effects, however, it seems probable that the principal ingredient was naphtha, with the addition of nitre, and perhaps sulphur. The use of naphtha, from its great inflammability, and the difficulty of quenching its flame, may account for the havoc and dismay which the Greek fire is said to have occasioned, and may have given rise to the stories of its burning with greater violence in water than in air, though a sufficient admixture of nitre, by the oxygen it gives out in combustion, might render such a composition for a time almost unextinguishable even by water. We are told too that it was employed with equal effect, by sea and land, in battles or in sieges. "In two sieges," says Gibbon, "the deliverance of Constantinople may be chiefly ascribed to the novelty, the terrors, and the real efficacy of the Greek fire. The important secret of compounding and directing this artificial flame was imparted by Callinicus, a native of Heliopolis in Syria, who deserted from the service of the caliph to that of the emperor. It was either poured from the rampart in large boilers, or launched in red-hot balls of stone and iron, or darted with arrows and javelins, twisted round with flax and tow which had imbibed the inflammable oil; sometimes it was deposited in fire-ships, and was most commonly blown through long tubes of copper, which were planted on the prow of a galley, and fancifully shaped into the mouths of savage monsters that seemed to vomit a stream of liquid and consuming fire. This important art was preserved at Constantinople as the palladium of the state: the galleys and artillery might occasionally be lent to the allies of Rome, but the composition of the Greek fire was concealed with the most jealous scruple. The secret was confined above 400 years to the Romans of the East. It was at length either discovered or stolen by the Mohammedans; and in the holy wars of Syria and Egypt they retorted an invention, contrived against themselves, on the heads of the Christians. The *feu Gregois*, as it is styled by the more early of the French writers, "came flying through the air," says Joinville, "like a winged long-tailed dragon, about the thickness of a hogshead, with the report of thunder and the velocity of lightning; and the darkness of the night was dispelled by this deadly illumination. The use of the Greek fire was continued to the middle of the fourteenth century, when the scientific or casual compound of nitre, sulphur, and charcoal, effected a new revolution in the art of war and the history of mankind."

Fire-Balls.

It should be observed, that in all probability many different inventions have been described under the general name of *Greek fire*. Although the invention has usually been ascribed to Callinicus of Heliopolis, in the reign of Constantine Pogonatus, A.D. 668, it seems highly probable that naphtha (which abounds in many parts of the ancient Persian kingdom, in India, and on the shores of the Caspian) had been applied to the purposes of warfare at a much earlier period by the Oriental nations. This subject has been ably discussed by Dr Macculloch in the *Quarterly Journal of Science, &c.* vol. xiv.

FIRE-BALLS, called also *Bolides* and *Fiery Meteors*, globular masses of fire which appear at a considerable height above the earth, shining occasionally with very great splendour, and sometimes leaving a luminous track behind them. The larger ones in this hemisphere proceed generally from north to south with great velocity, frequently exploding into globes of smaller size, and sometimes vanishing with a report, sometimes without one. They are not unfrequently attended with a discharge of solid compounds of earthy and metallic matters, called meteoric stones, the descent of which, though stubbornly denied for a time, was finally established about the beginning of this century.

These luminous appearances no doubt constituted part of the ancient prodigies, blazing stars or comets, which last they sometimes resemble in being attended with a train; but they sometimes appear with a round and well-defined disk. The first of these of which we have any accurate account was observed by Dr Halley and some other philosophers at different places in the year 1719. From the slight observations they could take of its course, the perpendicular height of this body was computed at about 70 miles above the surface of the earth. The height of others has also been computed, and found to vary from 33 to 100 miles. The velocity at which they travel is estimated at from 5 to 33 miles in a second. One of the most remarkable of these on record appeared on the 18th of August 1783, about nine o'clock in the evening. It was seen to the northward of Zetland, and took a southerly direction over an immense space, being observed in the

southern provinces of France, and, according to one account, at Rome. During its course it frequently changed its shape; sometimes appearing in the form of one ball, sometimes of two or more, sometimes with a train, sometimes without one. It passed over Edinburgh nearly in its zenith, and had then the appearance of a well-defined round body, extremely luminous, and of a greenish colour—the light which it diffused on the ground giving to objects a greenish cast. After passing the zenith it was attended by a train of considerable length, which continually augmented, and at last entirely obliterated the head, so that it looked like a wedge flying with the obtuse end foremost. The motion was not apparently rapid, by reason of its great height: though it must have moved with great velocity, on account of the immense space over which it travelled in a short time. In other places its appearance was very different. At Greenwich we are told that "two bright balls parallel to each other led the way, the diameter of which appeared to be about two feet; and were followed by an expulsion of eight others, not elliptical, seeming gradually to mutilate, for the last was small. Between each two balls a luminous serrated body extended, and at the last a blaze issued which terminated in a point. Minute particles dilated from the whole. The balls were tinted first with a pure bright light, then followed a tender yellow, mixed with azure, red, and green; which, with a coalition of bolder tints, and a reflexion from the other balls, gave the most beautiful rotundity and variation of colours that the human eye could be charmed with. The sudden illumination of the atmosphere, and the form and singular transition of this bright meteor, tended much to make it awful; nevertheless, the amazing vivid appearance of the different balls, and other rich connective parts not very easy to delineate, gave an effect equal to the rainbow in the full zenith of its glory."

Dr Blagden, in a paper on the subject inserted in the seventy-fourth volume of the *Philosophical Transactions*, not only gave a particular account of this and other meteors of the kind, but offered several conjectures as to the probable causes of them. The first thing which occurred to philosophers on this subject was, that the meteors in question were burning bodies rising from the surface of the earth, and flying along the atmosphere with great rapidity. But this hypothesis was soon abandoned, on considering that there was no power known by which such bodies could either be raised to a sufficient height, or projected with the velocity of these meteors. The next hypothesis was, that they did not consist of one single body, but of a train of inflammable vapours, extending a vast way through the atmosphere; which being kindled at one end, displayed the luminous appearances in question by the fire running from one end of the train to the other. To this hypothesis, which was broached by Dr Halley, Dr Blagden objected that no just explanation was given of the nature of the vapours themselves, the manner in which they were raised up, or their regular arrangement in straight lines of such vast extent; or how they could be supposed to burn in such rarefied air. "Indeed," says he, "it is very difficult to conceive how vapours could be prevented, in those regions where there is in a manner no pressure, from spreading out on all sides in consequence of their natural elasticity, and instantly losing that degree of density which seems necessary for inflammation. Besides, it is to be expected, that such trains would sometimes take fire in the middle, and thus present the phenomenon of two meteors at the same time, receding from one another in a direct line."

For these and other reasons the hypothesis of Dr Halley was abandoned, and another substituted in its place. This was, that the meteors in question are permanent solid bodies, not rising from the earth, but revolving round it in very excentric orbits, and thus in their perigee moving with inconceivable rapidity. Another theory supposes that the meteors in question are a kind of bodies which take fire as soon as they come within the atmosphere of the earth. Sir Humphry Davy's discovery that the earths and alkalies are metallic oxides, affords some plausibility to this theory, especially in cases where the meteors are accompanied with the descent of solid bodies to the earth. It has been suggested that the bases of the earths may exist in the meteor in a metallic state, and that when the body arrives within the range of our atmosphere, the strong affinity which it is well known these metallic bases have for oxygen causes them to unite and produce violent combustion. The origin of fire-balls has also been ascribed to the agency of electricity, and there seems little doubt that this is really the true way of accounting for them.

Falling or *shooting stars* are the same phenomena upon a smaller scale. See FALLING STARS, and METEOROLITES. Dispersed through the volumes of Von Humboldt's *Cosmos* the reader will find many curious and interesting observations on these phenomena.

FIRE-ARMS. See GUN-MAKING.

FIRE-DAMP. See DAMPS, and LAMP, *Safety*.

FIRE-ENGINE, a species of forcing pump in which the water is subjected to pressure sufficiently strong to raise it to the required height. Those of the ordinary construction consist of two forcing pumps, wrought by the reciprocating motions of two transverse levers. The water is forced into an air-vessel, by which means the inclosed air is condensed, and by its reaction it forces the water through a moveable pipe, which terminates in a conical form, and is directed upon the flame. Braithwaite's steam fire-engine is an ingenious application of the moving power of steam to the working of fire-engines. The mechanical arrangement of this machine consists of two cylinders of about six inches in diameter, one of them being the steam-cylinder, and the other the water-pump; and they are placed horizontally, so that a parallel motion is easily obtained. An engine of this kind will deliver about 9000 gallons an hour to the height of 90 feet. The time of getting the engine into action from the moment of igniting the fuel (the water being cold) is only 18 minutes. For further observations upon fire-engines, see HYDRODYNAMICS, chap. iii., sec. 2.

FIRE-WORSHIPPERS. See GUEBRES; MAGI; PERSIA; ZEND.

FIRKIN, a measure of capacity, being the fourth part of a barrel. The firkin of ale, which formerly was 8 gallons, by an act of 1803 was made 9 gallons, the same as the barrel of beer, or 9·15340 imperial gallons. The firkin of butter is equal to 56 lb.; that of soap, 64 lb.

FIRLOT, a dry measure used in Scotland, containing 4 pecks or $\frac{1}{4}$ of a boll. The Linlithgow wheat firlot (used also for rye, pease, beans, salt, and grass seeds) is to the imperial standard bushel as 0·998256 to 1. The barley firlot (also used for malt, oats, fruit, and potatoes) is to the imperial standard bushel as 1·4562794 to 1.

FIRMAMENT, in the ancient astronomy, the eighth heaven or sphere, with respect to the seven spheres of the planets which it surrounds. It is supposed to have two motions; a diurnal motion, given to it by the *primum mobile*, from east to west, about the poles of the ecliptic; and another opposite motion, from west to east; which it completes, according to Tycho, in 25,412 years; according to Ptolemy, in 36,000; and according to Copernicus, in 25,800; when the fixed stars return to the same precise points in which they were at the commencement. This period is commonly called the *Platonic* or *great year*.

FIRMAN, a passport issued by the grand vizier in the

name of the sultan to travellers and others. In the East Indies, the term firman is used for a written permission to trade.

FIRMICUS, MATERNUS JULIUS, a Latin writer who flourished under the successors of Constantine. About the year 345 he composed a work entitled *De Erroribus Profanarum Religionum*, which he inscribed to Constantius and Constans, the sons of Constantine, and which is happily still extant, accompanied with the annotations of John Wouver. To Firmicus are also attributed eight books on astronomy, first printed by Aldus Manutius in 1501, and reprinted several times since; but as this work contains nothing relating to the true science of astronomy, and is filled with astrological calculations after the manner of the Babylonians and Egyptians, Baronius doubts whether a good and pious Christian, as Firmicus is represented to have been, could have indulged in such profane and impious speculations. Cave, however, very reasonably supposes that he might have written these books anterior to the date of his conversion from Paganism. Of the treatise on the *Errors of the Profane Religions*, the principal editions subsequent to that of Aldus are, one printed at Strasburg in 1562, another at Heidelberg in 1599, and a third at Paris in 1610, all in 8vo; but afterwards it was conjoined with Minucius Felix, and printed at Amsterdam in 1645, at Leyden in 1652, and again at Leyden by James Gronovius, in 1709, 8vo. It is likewise to be found in the *Bibliotheca Patrum*, and at the end of Cyprian, printed at Paris in 1666. (Dupin; Cave; Moreri; Fabricius, *Bibl. Lat.* and *Bibl. Lat. Med.*) (J. B—E.)

FIRST-FRUITS (*primitiæ*) are frequently mentioned by ancient Christian writers as forming part of the church revenue. In the Church of England, first-fruits are the profits of every spiritual living for the first year, according to the valuation thereof entered in the King's Books. *Tenths* are the tenth of the yearly value of such living, given anciently to the pope throughout all Christendom, but in England, by statute 26th Henry VIII. cap. 3, transferred to the king. By statute 27th Henry VIII. cap. 3, no tenths are payable the first year, as then the first-fruits are due; and, by several statutes in the reign of Queen Anne, benefices under L.50 per annum shall be discharged of the payment of first-fruits and tenths. She also gave up the revenue arising from first-fruits and tenths, and by act 2d and 3d of her reign, cap. 2, established a perpetual fund therefrom, vested in trustees, for the augmentation of poor livings. This is called *Queen Anne's Bounty*, and is further regulated by subsequent statutes. By 3d and 4th William IV., cap. 37, the payment of first-fruits in Ireland is abolished. (See Burn's *Ecclesiastical Law*.)

FISC, (Lat. *fiscus*), in *Civil Law*, the treasury or revenue of a state. Fiscus in its primary sense denoted a basket or hanaper used by the Romans for holding large sums of money, and hence was applied to a money-chest or a purse. Under the emperors the term fiscus came to be applied to the imperial revenue or privy purse, in contradistinction to the *ærarium* or public treasury. Ultimately, when the emperors had concentrated in themselves the whole sovereign power, the word fiscus lost its distinctive character, and was used in the same sense as ærarium under the republic. Various officers were employed in the administration of the fiscus; as procuratores, advocati, patroni, and præfecti. From fisc is derived the word confiscation, which signifies to take the goods of a condemned person and appropriate them to the public treasury.

FISH. See ICHTHYOLOGY.

FISHER, JOHN, Bishop of Rochester, was born at Beverley in Yorkshire, in the year 1459, and educated in the collegiate church of that place. In 1484, he removed to Michael House in Cambridge, of which college he was elected master in the year 1495. Having applied himself to the study of divinity, he took orders; and becoming eminent as a divine, attracted the notice of Margaret, Countess of Richmond, mother of Henry VII., who appointed him her chaplain and confessor. In 1501 he took the degree of doctor in divinity, and the same year was elected chancellor of the university. In the year following he was appointed Lady Margaret's first professor of divinity in Cambridge; and in 1504 he was consecrated Bishop of Rochester. It is generally known that the foundation of the two colleges of Christ-Church and St John's, Cambridge, was owing to Bishop Fisher's influence with the Countess of Richmond; he not only formed the design, but superintended the execution, and was appointed by the statutes visitor for life after the death of Lady Margaret. On the promulgation of Luther's doctrine, the bishop was the first to enter the lists against him. Upon this occasion he exerted all his influence, and is generally supposed to have written the book on account of which Henry VIII. obtained the title of *Defender of the Faith*. Hitherto he had continued in favour with the king; but in 1527, having opposed his divorce from Catherine of Aragon, and denied his supremacy, he was soon exposed to the full brunt of that monarch's resentment. In 1533 the parliament found him guilty of misprision of treason, for concealing certain prophetic speeches of Elizabeth Barton, a fanatical impostor known as the Holy Maid of Kent, relative to the king's death, and condemned him, with five others, to suffer loss of goods and imprisonment during his majesty's pleasure. He was subsequently released upon payment of a fine of L.300.

King Henry having now espoused Anne Boleyn, his obsequious parliament took the oath of allegiance. But in this oath the Bishop of Rochester steadily refused to join, alleging that his conscience had not been convinced that the king's first marriage was against the law of God. For this refusal he was attainted by the parliament of 1534, and committed to the Tower, where he experienced cruel treatment, and would probably have died under his sufferings. It was now that Pope Clement, at once to reward Fisher and spite the king, sent him a cardinal's hat. This kindness, however, only hastened the bishop's ruin. The king, bent on his destruction, sent Rich the solicitor-general, under the pretence of consulting the bishop upon a case of conscience, but really with a design to draw him into a conversation concerning the supremacy. The honest old bishop spoke his mind without suspicion or reserve; and an indictment and conviction of high treason were the consequence. He was beheaded at Tower Hill on the 22d of of June 1535, in the seventy-seventh year of his age. It is impossible to withhold from Fisher, notwithstanding his inflexible enmity to the Reformation, the character of a learned, pious, and honest man. His works attest his learning; his inflexible zeal for his faith, and the readiness with which he died for his creed, plainly prove his honesty as well as his piety.

The Bishop of Rochester was the author of a number of works, of which the following is a list:—*Assertionum Martini Lutheri Confutatio; Defensio Assertionis Henrici Octavi de Septem Sacramentis; Epistola Responsaria Epistolæ Lutheri; Sacerdotii Defensio contra Lutherum; Pro Damnatione Lutheri; De Veritate Corporis et Sanguinis Christi in Eucharistia, adversus Œcompoladium; De Unica Magdalena; Petrum fuisse Romæ;* Several Sermons, amongst which was one preached at the funeral of Henry VII., and another at that of the Countess of Richmond; His opinion of King Henry the Eighth's marriage, in a letter to T. Wolsey, printed at the end of the second volume of Collier's *Ecclesiastical History*. Most of the tracts above mentioned were collected and printed in one volume folio, at Wurtzburg, in 1595. Fisher, as already stated, is supposed to have had a considerable share in the composition of Henry's book entitled *Assertio septem Sacramentorum;* and in the Norfolk library of manuscripts belonging to the Royal Society there is an answer made by him to a book printed at London in 1530, concerning Henry's marriage with Queen Catherine.

FISHERIES.

FISHERIES are of high importance to almost all nations, and peculiarly so to those whose territories are either entirely insular, or partially bounded by the sea. The direct and chief advantage is, of course, to such people as capture, as well as feed upon, the finny tribes; but the curative process, whether for a lengthened period by means of salted pickle, or for a shorter preservation, by the use of ice, now spreads the benefit far inland, into many a distant land which never heard the surging of the sea. As the great nursery for sailors, and the producer of habitual hardihood, and a fearlessness of winds and waves, our British fisheries are altogether invaluable—that is, they greatly transcend all those merely pecuniary advantages, however great, which can be calculated and made manifest by statistical documents of whatever kind. Sir Henry Wotton was of opinion that there was something in the capture of fish, even when pursued as a trade, which tended to improve the moral, if not the intellectual character of those engaged in it, and to bring them up for the most part, however unlettered, as a patient, simple, humane, and hardy race—not insensible, in the midst of stormy days and nights of darkness, to the sublime feeling of dependence on a higher power, and with a preparedness to acknowledge and obey the divine will. We are told from the highest source that they that "do business in the great waters, these see the works of the Lord, and his wonders in the deep." How far they are permanently impressed thereby, to their own advantage, we are not prepared to say; but the difficulties which beset their adventurous calling, and the early period at which their professional life commences, and becomes of value, make it all the more incumbent upon others to attend both to the educational and spiritual interests of a peculiar people to whose hardihood we owe so much. "Men-of-war, and merchantmen," writes Sir Robert l'Estrange, "consume men and breed none; the collier brings up now and then an apprentice, but still spends more than he makes; the only other and common nursery of seamen is this fishery (that of herrings), where every buss brings up, it may be, six, eight, or ten new men every year, so that our fishery is just as necessary to our navigation as to our safety and well-being. And it is well observed that all the princes are stronger or weaker at sea, according to the measures of their fisheries." Lacepede regards the herring as "une de ces productions dont l'emploi décide de la destinée des empires;" and the great Cuvier has recorded that the government of all nations possessed of any sea-coast where that fish is known, has given special attention and encouragement to its capture—regarding such occupation as the finest nursery for the formation of robust men, intrepid sailors, and skilful navigators, and so of the highest consequence towards the ensuring of maritime greatness. This remark, it has been well observed, coming from the native of a country with a limited sea-coast, has irresistible force when applied to islands like Great Britain and Ireland, possessed of immense colonies in every quarter of the earth, "on whose dominions the sun never sets," and thus requiring unceasing supplies of seamen for a naval and commercial marine of greater size and power than any known in ancient or modern times. Let these authorities suffice as an introductory exordium.

It does not matter much which department of our subject we begin with. Let us take up the fresh waters first, and in these, we need scarcely say, the most important species we can encounter is the salmon—*Salmo salar* of naturalists.

As regards the historical view, we may state, that the ancients knew little of trout, and nothing of salmon, which are the glory of the group. If observed in any way by the Greeks, the latter would not have escaped the notice of the lynx-eyed Aristotle. The salmon is not a Mediterranean species, and so does not occur in such of the rivers of France as debouche into that inland sea. It is cursorily alluded to by Pliny, who of course does not describe it as an Italian fish, but as native to certain rivers in Aquitaine. Ausonius is the first Latin poet who mentions the salmon under its present title:—

> Nec te puniceo rutilantem viscere, Salmo,
> Transierim:

And in another place he writes of,

> Purpureisque salar stellatus tergora guttis.[1]

We have here to do, however, with the natural and commercial rather than the classical history of the finny tribes, and so shall proceed to consider them as they are known to us in this our day.

The parent salmon show themselves at the mouths of rivers, and endeavour to ascend the same during almost every month throughout the year, although the process of spawning does not usually take place till winter, that is, from the beginning of October to the close of January—November and December being the principal months in the majority of rivers. They generally delay their ascent in any great number till the streams are somewhat swollen by heavy rains, although in the lower portions of the larger rivers there may be a more frequent *run*. When the *fresh* or flood has fairly intermingled with the estuaries the upward movement is often rapid and multitudinous, especially if there has previously occurred a long continued course of dry weather.[2] This marvellous instinctive desire to return to their native streams is irrepressible. It induces them to stem the current of surging rivers, to force their perilous way into many a "hell of waters," to ascend precipitous falls, and pass over weirs and similar obstacles of human intervention, which no other or less pervading power could either vanquish or evade.

The spawn is deposited in troughs made by the parents to a considerable depth in the gravel, and is afterwards covered over in like manner. Both sexes are necessarily present, but observers differ as to the share assumed by the male in the removal of the gravel, and whether the female, supposing that she is the chief builder, makes most use of her head or tail.[3] According to Mr Andrew Young, the fish al-

---

[1] An amusing and instructive volume on the literary history of fish has been recently published. See *Prose Halieutics, or Ancient and Modern Fish Tattle.* By the Rev. C. D. Badham, M.D., London, 1854.

[2] The greatest haul of salmon that we know of on record, is that which befel the fishermen of Thurso, more than a century ago. At a single sweep one day in July the enormous number of 2500 were secured. A large net was used sweepingly, from the cruives of the river down to the lower end of the pool, being taken by 18 or 20 men, who kept the ground-rope low with long poles. The fish (including, we doubt not, grilse, as well as adult salmon) were afterwards taken ashore in a smaller net.

[3] Mr Shaw is of opinion that the labour of the trenches devolves upon the female, and that the excavation is performed chiefly by a flapping movement of the tail, which is obviously an engine of great force in fishes. The same observation, or rather inference, had been made (unknown to Mr Shaw) by Mr Potts, in relation to the Tweed salmon, as long since quoted by Pennant in his *British Zoology*. That gentleman regarded the tail as the instrument by which the gravel is displaced, in consequence of his having so frequently found that part rubbed or abraded as it were by violent action. Mr Fraser of Dochnalurg (to whom we owe a pamphlet on the salmon

Spawning of salmon.

ways approach the spawning bed in pairs. The places usually selected are rippling fords or shallows of not more than two or three feet in depth, sometimes less, where the gravel is clean and not too heavy, and the water clear and in constant flow. Their first object is to dig a trench, a work of some labour, as they prefer a somewhat firm or compacted bed, less liable to shift than one of looser gravel. They begin the operation by falling down a few yards below the chosen spot, and then tilting up against it with their heads, thus by repeated efforts displacing a portion of the gravel, and so forming the commencement of their first parallel. The excavation varies in depth from nine to eighteen inches, according to the nature and consistence of the material, or the requirements of the situation, of which, no doubt, the fishes themselves are the best judges. When the trench is regarded as of sufficient depth, the female deposits in it the ripest portion of her ova, and the male sheds his milt among them. A careful observer may perceive both products falling into, and settling at the bottom, and as soon as all is right in that respect, another tilting takes place against the gravel, the effect of which is to continue the trench, while the loosened materials are aided in their movement by the current, and falling into the previous hollow, help to cover up the ova. This higher portion in like manner receives its share of ova and milt, and so the work proceeds till it is finished. In this labour several days may be consumed. The parent fish then fall down the river into the first deep they come to, and there they abide for a time for repose and restoration. They are usually much discoloured at this period, the females dark and inky, the males streaked and stained with rusty red, and the under jaw very obtrusive, and upturned into a snout or *kip*. They then gradually make their way through stream and pool towards the tideway, and by this time, although flabby and flavourless, their stains have been in a great measure washed away, and the silvery lustre re-assumed. Hence the Scotch expression of "a weel-mended kelt," signifying a fish in this half-recovered but still impoverished condition, and which the deluded (and deluding) angler not seldom seeks to glorify by the name of salmon. The majority of early spring fish taken by the rod are kelts, and many a man would much rather never fish at all than kill a score of them. In general the males are the first to leave the river, many of the females abiding there till March or even May, especially in dry weather when they cannot pass in safety downwards from pool to pool. It is believed that they no sooner reach the salubrious sea than their muscular firmness, fine flavour, and brilliant lustre are restored. They then increase rapidly, and after a few months return to the rivers as beautiful, and far bigger than before—the soonest down being probably the earliest to re-appear. So much for the old fish.[1] Let us now inquire after the spawn.

Early state of salmon.

The period of hatching of the ova varies with the rigour of the season and the time of deposition. If spawned early the young will burst their cerements in from 90 to 100 days, while such as are laid in December may require 140 days before they break the shell. There are also intermediate periods corresponding to the temperature of the place or season. The fry are at first very slender, but extremely agile little things, about three-quarters of an inch in length, with none of the fins distinctly developed save the pectoral, and bearing beneath the body a comparatively large bag of a beautiful transparent red, like a pale-coloured currant, attached to the abdomen, and affording the young fish an ample supply of nourishment for several weeks. This is the yelk or vitelline portion of the egg. They continue for a length of time to keep themselves in a great measure concealed from public view among the stones and gravel, are quick-sighted as well as active, and have the instinct of self-preservation so strongly implanted from the first, that the waving of the smallest wand, or the passing shadow of an outstretched arm, is sufficient to cause their instantaneous disappearance among the multitudinous little caves and arched recesses with which their shingly bed abounds. While quiescent, they seem to be almost in a helpless state, and are not only borne down but overbalanced by the pea-like body attached to the abdomen, and which, gravitating in accordance with its own constitution, throws the fry over on their sides. In this position they so resemble the subjacent soil, that though a score of them may be lying in the impressed mark of a horse's hoof, they can only be discovered by the brilliant colour of their "provision bag." As soon, however, as they are set in motion they assume their natural position, and swim away with the bag beneath them, and with great facility. They continue in this independent and inconspicuous state for several weeks, being nourished all the time, so far as has been ascertained, by the gradually absorbed remains of the vitelline portion of the egg, which constitutes the bag just mentioned. The period of absorption seems to vary with

isheries) describes the action as resembling that of a hen shuffling with her wings in earth or sand. The spawners, he alleges, lie on their sides, and, while making the furrows, remove the gravel by a quick jerk and curvature of their bodies, but principally by the fins and tail. At this period, as he further informs us, they are always accompanied by a horde of trouts, which are very alert in picking up the ova as they drop, and the male spawner is every now and then seen chasing them away.

The following are Mr Shaw's most recent observations, regarding the same process as performed by the common river trout, *Salmo fario*, and which he regards as confirming by analogy the proceedings of the salmon. "I have had many excellent opportunities this last autumn of observing the interesting process of trouts depositing their spawn in a small stream which runs into a well-stocked loch in this neighbourhood. The stream in which they were spawning was not more than six inches deep, and the fishes were as distinctly seen as if in a glass on the drawing-room table. By creeping up to them on hands and knees under the shade of a dark bush, I was able to watch them for hours unseen, and so near that I could have put my hands on them with ease. The male, as I have already often stated, took no part in the process of digging, contenting himself by keeping nearly parallel with the female, and close to the bottom of the spawning bed when at rest. The female, while in the act of removing the materials, always had her head a few inches above the level of the gravel at the bottom, while her tail was at the same time working actively on the gravel immediately under it, and the small pebbles could be distinctly seen in motion at the same time. I do not mean to say that the female salmon removes the gravel with her tail, as if actually with a spade, but that by the broad surface of the caudal extremity acting vertically on the water near the bottom, that water readily removes the gravel below, which is always loose and shingly on spawning streams. In short, the fact of the salmon removing the gravel by the action of the tail can no longer admit of a doubt."—MS., 16th March 1855.

[1] We have reason to believe that salmon suffer by a *forced* retention in the sea, as well as from a too prolonged sojourn in the fresh waters. A case of this kind is supposed to have occurred at the mouth of the Grimsta, in the island of Lewis, in August 1852. During a continuance of dry weather at that time, the fish were found dying in great numbers in the salt water, just off the river's mouth; and this was attributed to their inability from want of water to ascend the stream. The immediate ailment, whatever might be its cause, seemed to be a softening and slight discoloration of a part of the upper portion of the skull, with an appearance of sinking or indentation in its centre: a specimen was kindly transmitted to us by Mr Francis W. Wilson for examination. We have preserved the skull. Another cranium of a salmon in our collection is slightly disorganized from a different cause. While a friend was playing a kelt one morning in early spring, near Cardrona, on the Tweed, our notice was attracted by a bright red light (the signal of danger) which the fish seemed to bear aloft upon its forehead. When stretched upon the dewy turf, we found on closer examination that there was a large fresh wound, which seemed nearly to have fractured the skull, laying it bare for about a couple of inches. It had no doubt been quite recently inflicted by a violent though misdirected blow from a leister, and yet the fish had not been so sickened thereby as to lose its appetite for artificial flies, one of which, though a frail thing compared with a poacher's trident, had just caused its capture.

Early state of salmon.

the temperature and other circumstances, and admits of a range of from 27 to 50 days. While lessening, it assimilates somewhat in colour to the rest of the body, and finally disappears. That animalcular food is also, towards the conclusion of this period, obtained through the mouth, there need be no doubt. It is not, however, till they are nearly two months old that they can be perceived as in pursuit of prey.

The growth of salmon fry is by no means rapid during their first summer. For several months they require to be narrowly looked for among the shingle (into which they are so fond of darting) before they can be seen. But as at this period, and throughout the season, our rivers are amply stocked with small fry of the same kind, but much more conspicuous from their larger size, and less timid habits, it becomes evident that we have two broods in hand, the smaller of which are the product of the immediately preceding spring, the larger that of the spring of a year and some months passed and gone. Both broods taken together constitute what are termed *parr*, and the larger set are those which afford such frequent though improvident amusement to the more juvenile class of anglers. Now the great constitutional change which converts an old parr into a young salmon (commonly called a smolt) takes place in spring, and consists mainly in the following alterations. The black spots upon the opercles or gill-covers disappear; the pale-coloured pectoral fins become deeply suffused by an inky hue at their extremities; the broad and conspicuous bars or blotches on the sides are effaced or rendered invisible, and the prevailing hues of dusky brown and yellowish white are converted into a dark bluish black upon the upper parts, and into a brilliant silvery white upon the lower sides and abdomen. The old opinion was that salmon fry grew to the length of six or seven inches in as many weeks. What led to this long-continued error was the rapidity with which the mature parr assumed the aspect of the acknowledged smolt. Superficial observers, and almost all were so on this particular point at the time referred to, taking cognisance, first, of the hatching of the ova in early spring, and secondly, of the sudden appearance and seaward migration of smolts so soon afterwards, erroneously imagined these two facts to take place in immediate or speedy succession and connection, whereas in truth they had no more to do with each other than an infant in the nurse's arms has to do with any active lad who may be setting forth to push his fortunes in a far country. It is now known and universally admitted that the parr remains at least an entire year in the fresh water streams before it becomes a smolt, so that the latter is necessarily not of the same generation as those hatched during the spring, in which it seeks the sea.

We owe the demonstration of this important fact, which had been previously nothing more than surmised, to Mr John Shaw of Drumlanrig. The essential value of Mr Shaw's discovery consists in his having proved the identity of that abundant little fish commonly called parr, with the young or earliest condition of the salmon. He also showed its long continuance in fresh water, its after conversion into the smolt, and the consequent absurdity of supposing that the latter went off to the sea in a few weeks after it was hatched. The importance and originality of his observations are independent of the fact—whether a certain portion of parr require one or two years in fresh water.

That excellent observer had been long convinced, in opposition to the prevailing sentiments upon the subject, that the small and most abundant, though by no means well-known fish, commonly called *parr*, was the young or natural produce of the salmon, and that all previously recorded attempts to trace the true history of the latter noble species in its early state were delusive and without foundation. So far back as the 11th of July 1833, he captured a few score of these small fishes, and placed them in a commodious pond, supplied by a wholesome streamlet, where they were as happy as the day was long. They throve and prospered to a wish, and in the ensuing month of April began to assume a somewhat different aspect, and in the earlier part of May were converted into what are usually called *salmon smolts*—that is, they lost the perpendicular or transverse bars, became of a fine deep blue upon the back. the sides and under portions being as lustrous as silver, and the scales deciduous, or coming easily off upon the hand In March 1835 he renewed the experiment, by taking from the river about a dozen parr of a large size—that is, about six inches long. They at this time bore the transverse blotches, and all the other obvious characteristics of the so-called parr. He transferred them to his pond, and by the end of April of the same year they too assumed the livery of the salmon fry, the dark bars becoming overlaid by silvery scales. It is clear that if *all parr* were converted into smolts when they were only about a year old, then so soon as the smolting process and the immediately ensuing migration to the sea have taken place, none would remain in the river except the small and inconspicuous fry of a few weeks old, already referred to as the darkling denizens of the shingle. But as this is not the case—as June, July, August, and so on, have from the first their shapely well-grown parr, besides those more minute and unobtrusive relatives amid the stones below, we can draw no other conclusion than that which Mr Shaw has drawn—to wit, that all the larger summer and autumnal parr are in truth young salmon advancing into their second year, and not ripe for the smolting process till the ensuing spring, by which time of course they must be two years old.

Identity of parr and smolts.

Prior to this ingenious identification of the parr and salmon smolt, and the demonstration of the lengthened sojourn of the latter in fresh water, the former was unavoidably regarded as constituting in its proper person a distinct and permanent species—that is, a continuous and inconvertible parr. What might be its early history no one knew, and as no female parr with matured roe had been ever met with, a considerate observer must have been sorely perplexed when he thought of its maternity. Its predecessors and posterity were alike a mystery—the only ascertainable fact being a truism, and fortunately self-evident, that the existing race existed. Mr Shaw, while making in the month of May 1834 a minute examination of some streams in which salmon were known to have spawned during the preceding winter, found there in vast numbers a very minute but extremely agile fish, which, from its position, he naturally concluded to be the young parr or actual samlet of the season. To test the truth of this opinion he scooped up a few score, the individuals not measuring more than an inch long. He placed them in his ponds, where they throve well, although after the lapse of an entire year they were only three inches and a half in length. At this time (May 1835) they entirely corresponded to the small or medium-sized parr to be seen in the natural streams of the river, and neither the free nor the captive brood of these dimensions exhibited any tendency to assume the silvery aspect of the smolt. Our observer, however, felt satisfied, from the result of his former tentative experiments on the parr, that they would ultimately assume that aspect; so he allowed them to bide their time, and accordingly in May 1836 they were transmuted into smolts or salmon fry. They then measured six inches and a half in length, the colour of the dorsal region being a fine bluish-black, the sides and abdomen silvery white, the dorsal, caudal, and especially the pectoral fins tinged with black. The smolts in the river were at this time descending seawards,—no difference could be discovered between these and their brethren in captivity,—the latter were *known* to have completed their second year, and so Mr Shaw very naturally asks,

Age of smolts.

"Is it likely that those in the river were only a few weeks old?"

It thus appears that the fry of salmon may be seen by any careful observer, in such rivers as produce them, early in the month of April, but so young and weak, in consequence of their recent emergence from the spawning beds, as to be unable to struggle with the current. They therefore betake themselves to the gentler eddies and other quiet places during spring and the earlier part of summer; but as they gain an increase of size and strength they begin to scatter themselves more independently over all the shallower portions of the river, especially where the bottom is composed of fine gravel. They thus continue comparatively unobserved throughout the whole of their first summer, during which they seldom take the angler's fly. But no sooner do the two-year-olds, according to Mr Shaw's theory, disappear as smolts in spring than these smaller fishes, now entering upon their second season, become bolder and more apparent, and then constitute, and continue for another year to constitute, the parr of anglers and of other observers. Their shy and shingle-seeking habits during the early months of their career so screen them from ordinary observation as to have induced the erroneous belief already mentioned, that the silvery smolts were the actual produce of the very season in which these are first observable, and were only a few weeks old—the fact seeming to be, that prior to their seaward emigration they had dwelt for a couple of years in "rivers of water." Now that we know this strange history, it seems still stranger that in the days of our ignorance no angler should have troubled himself to inquire what became of the older generation of parr—that is, of the comparatively large individuals which may be captured late in autumn and in early spring, but scarcely one of which can be detected after the departure of the smolts into the sea. If the two were not identical, how did it happen that one so constantly disappeared simultaneously with the other? But their identity has been demonstrated, and the disappearance of these full-grown parr is caused by their conversion into smolts.

In giving Mr Shaw's view of the comparatively slow progress of the development of parr, and stating our own belief, for the reasons assigned, in the general truth of the *biennial* theory, as it may be called, we must not omit to state that several excellent, experienced, and trustworthy observers have come to another conclusion, and, while admitting the value and importance of Mr Shaw's discoveries, maintain that a single completed year suffices to convert a parr into a smolt. It may be here mentioned, that in the course of Mr Shaw's experiments, it happened each time that some of his captive specimens *smolted* when they were little more than a year old; and this, say some, instead of being an exceptional occurrence, was rather an indication of what would have happened to the whole, had they been in their natural and unconstrained condition in the open river, instead of being shut up in a pond. We think Mr Shaw has fenced the matter well, by showing that a similar change was very obviously going on in the river among the larger and older parr, but not among the younger and smaller; and his opponents can in no way explain or account for (consistently with their *annual* theory) the continuance of so many obviously year-old parr in the river for such a continuous length of time after the departure of the smolts in spring. At the same time it is proper to consider the facts on both sides. Mr Andrew Young of Invershin, who has well availed himself of the amplest opportunities for experimental observation, informs us that the fry (or parr) of his ponds became smolts at the end of the first year, and that frequent trials brought forth the same result. We have every confidence in Mr Young's statements, and therefore know not how to reconcile the opposing facts. This much, however, consists with our own knowledge, that the river Shin, by the banks of which Mr Young's experiments were made, abounds *all summer* with well-grown parr in their second season—that is, we find them there, as elsewhere, for many a month after the smolts have taken their departure to the sea. These specimens we have not seldom had it in our power to exhibit to Mr Young himself. We observe that Mr Ramsbottom has also recently followed the same course. He observes, in a note addressed to us from the banks of the Shin, and dated 12th May 1855, "I killed for him (Mr Young) in his own river, with a small midge fly, both the year-old parr and the two-year-old smolt, and could kill a hundred of both ages in one day if he required them." And we continue to find them in, and to have them transmitted from, numerous other salmon rivers. They are now (August 1855) plentiful in the Tay, although the smolts are long since gone. It will be seen then that Mr Young's opponents may also on their part assume that his cases might be deemed exceptional, by reason of being pond-bred, and that they were thereby rendered more mature—just as he alleges that Mr Shaw's were made exceptional by the same means though in the opposite direction, being retarded rather than hastened in their great change.[1] The truth is that perfect accuracy of observation is by no means easy, even with the best intentions. Of this we have a good example in the reports published from time to time regarding the parr brought up in the great and successful breeding pond at Stormontfield, a few miles above Perth. The ova were deposited after subjection to the artificial or mechanical process of impregnation in the winter of 1853, and were hatched in the spring of 1854. Though necessarily of very small dimensions during the first summer, they throve well, and were reported on as being not only a healthy colony of young fish, but as by the month of October attaining "nearly the size and getting the silvery appearance of smolts." This silvery appearance had never been seen or heard of before, as manifested by any parr of salmon born, when it was scarcely seven months old. Nothing of the kind was observable in any of the natural streams of Scotland. So also, early in the ensuing month of April a party of gentlemen from Perth visited the ponds, and brought back with them "a smolt completely covered with silvery scales, and fully as forward as any at present in the river. The fish was caught with the rod and a small fly, and was the only one that rose, and may be considered as *a fair average specimen of what the pond contains.* In shape it is faultless, being finely grown, and the parr marks obliterated by the newly-acquired scales. So this long-disputed question has at length been settled, and Mr Andrew Young's, of Bonar Bridge, statement has been proved the true one." If by this it was meant that *all parr* assume the aspect of smolts, and become fit for their seaward migration when little more than a year old, the

[1] In regard to these supposed exceptional cases, Mr Shaw, in a recent letter, observes as follows:—"The circumstance of some individuals assuming the smolt condition at the end of twelve months, in each brood, does not in the least degree invalidate my statement that *by far the larger portion of them do not.* The smolts of the Nith have now all departed for the sea, and consequently the truth of what I have so often stated is at this moment very clear, there being no other parr to be caught with the fly but the *one-year-olds,* measuring from 3½ to 4 inches long, while the young of this year measure about 1¼ inches. There is one very important fact which has escaped the notice of my opponents, that is, the characteristic condition of the male autumnal parr, in respect to the *maturity of its milt,* not one of the persons connected with the Perth ponds having ever asserted that even a single sample of their brood had been yet found in that condition. Now it is notorious to every one that parr are found in thousands in that state every autumn, in every salmon river, and that they are then capable of reproduction."—MS., June 11, 1855.

Age of smolts.

conclusion is certainly erroneous, and can easily be disproved. We believe there is some risk that, when the matter under discussion comes to bear upon the commercial or industrial branches of the subject, the wish may be the father of the thought. As all parr in spring, just like the feathered tribes during the same season, become beautified by a great freshening in their general aspect—an increase of blue and silver, a decrease of brown and yellow —they are thus apt to be designated as smolts, when they are really far from that condition. The term, too, is very vaguely applied. All parr are smolts in the sense that they are young salmon, but the title, to avoid confusion, ought to be restricted to that brief period of the spring in which these small fishes have changed their barred and spotted livery into a more contrasted coating of bluish-black and shining silver, and are at the same time under the influence of the migratory movement to the sea. Of course this universal conversion at a year old, if the correct view, would be by much the more advantageous one for the artificial breeder, in so far as, in the rearing of his young fish, he would save a year's care and keeping; and where there is only a single artificial pond, that pond might be emptied of its contents each season, and the newly-hatched fry let down into it from the spawning-troughs above, without any risk of their being swallowed alive by their stronger if not more carnivorous connections.

Having our own prepossessions in favour of Mr Shaw's views, although we trust without undue bias from any spirit of partizanship, we felt anxious to satisfy ourselves by personal inspection regarding facts which did certainly not accord with our own experience. So in company with Mr Shaw, we availed ourselves of an invitation to meet the parties principally concerned at Stormontfield on the 2d of May 1855. This was more than six months after the time of these fry having been first reported as assuming the smolt aspect, and a few weeks after that of their being for the second time so reported. We shall now state what occurred. The most ample opportunity and every convenience were afforded us for a satisfactory examination of the contents of the pond, which is excellently well constructed for the purpose in view. We saw many thousands of these imprisoned parr with sufficient distinctness to receive a correct impression of their actual state; and we moreover netted a sufficient number to serve as representatives for a closer and more minute examination. Although these fish were by that time at least about thirteen months old, and were in fine condition, *there was not a single smolt among them.* They corresponded entirely to the year-old parr, which we took for comparison from the adjoining river Tay. The only example of a smolt exhibited to the meeting, in the course of a careful and prolonged investigation, was one caught by a gentleman while angling *in the river*, and who had tried his skill for a corresponding specimen in vain within the precincts of the pond. He brought it up to us without delay, and when placed in a vessel beside the pond-bred parr, its greater size, more salmon-like shape, and spotless silvery lustre, made its difference of aspect obvious to all. The meeting, therefore, came to the unanimous and unavoidable conclusion that the multitudinous inhabitants of the pond were still, without exception, parr; and in this opinion Mr Shaw and the writer of this article cordially concurred. Lord Mansfield and others pressed for their detention for another year, and their continued captivity was, as we understood, determined on.

Age of smolts.

We here record only to the extent that we have personally ascertained and seen. But we doubt not that fishes, like flies and flowers, are under the influence of temperature, and as the preceding winter and spring were seasons of great severity, an unusual retardation may have taken place. Mr Robert Buist of Perth, to whom we have been indebted for much valuable information on these matters, informs us that in the course of a week or two after our visit a marked change took place, and that a great number of smolts, in the genuine silvery state, began to show themselves, while many others exhibited unmistakable symptoms of a corresponding change. It is not alleged that this conversion was complete or universal, but we can entertain no doubt, from the evidence laid before us, that at least a transformation of some kind occurred. Samples have been sent us which, though somewhat discoloured by the medium in which they were preserved, seem to have lost the parr markings, and assumed the silvery aspect. We do not know in what proportion this took place, but we may presume, from the ascertained fact of so many midsummer parr of good size being still found in the Tay, that these would have continued and been recognised as likewise in the ponds, if not set at liberty with their more brilliant brethren. The determination as to further detention was, however, altered, the sluice was lowered, and the fry allowed their freedom.[1] We have no doubt they will make a good use of it, and that such as prefer a second season in fresh water will rejoice in the pleasant reaches of the Tay. Meanwhile the thing to guard against on the one side is the assertion that *no parr* becomes a smolt till the termination of its second year, and on the other, that *all parr* become smolts soon after the conclusion of their first twelvemonth. If it takes some time to prove the former statement, there is scarcely a day in the year in which we cannot disprove the latter.

We have ourselves repeatedly demonstrated, by observations of the easiest and most simple kind, that there are three distinct stages or different broods of parr, that is, young salmon, in our rivers during early spring. We have, *first*, those which, recently excluded from the ova, are still, if not invisible to common eyes, so small and inconspicuous as to be unobservable till notice is directed towards them. We have, *secondly*, those which are just completing their first year, and which, owing to the continued cold of the preceding winter, and consequent deficiency of insect food, are very little larger than they were at the end of the preceding month of October—seldom measuring more than three inches. They increase, however, rapidly as the summer advances, and then form the obvious and admitted parr which stock our rivers. We have, *thirdly*, for a short time, along with the two preceding broods, those large and (so far as concerns the males) sexually developed parr, which have completed their second year, and are characterized by their brightness as well as size. In the months of April and May these lose the parr appearance, are converted into silvery smolts, and immediately take their departure downwards to the sea. After this all those parr that are only a year old, or a little upwards, are found in the *rivers* (whatever they may be in the ponds) apparently as numerous as ever.[2]

[1] "The rapid growth of the fry, the large proportion which immediately progressed into indisputable smolts, and the striking evidences which the larger inhabitants of the ponds themselves clearly manifested that the time of migration had really arrived, led to the wiser resolution of the committee, that the more advanced and matured of their charge should be allowed to follow the dictates of their nature." *Perthshire Courier*, 26th July 1855.

[2] Mr Ramsbottom of Clitheroe, who has had great experience as an angler, and has of late been largely employed in conducting the process of artificial impregnation, of which he has watched the results, records his opinion as follows:—"Artificial propagation has not only proved and settled this great question, but it has taught me to see it in thirty-three different rivers in Great Britain and Ireland, in which I have angled with the rod. You must understand that the parr or salmon fry, towards the close of the second year, has to undergo a change which it cannot attain to in its first. Every male fry or parr belonging to the salmon gets a developed milt at the close of its second year, and parts with it in winter in the spawning bed of the adult salmon. It then becomes a smolt in spring, just

Constitution of the male parr.

We may now notice some anomalous and very peculiar circumstances connected with the natural constitution of the parr, which some have recently supposed to throw great light upon this vexed question, if they do not reconcile its apparent contradictions. It is well known to every experienced observer that a va-t proportion of the larger parr so frequently referred to are males; that is, that so far as any sexual characteristics are manifested, it is the milters alone which show such signs. The male parr is sexually mature when sixteen or eighteen months old (of course, if converted into smolts when a year old, they could have no existence at such an age), while the female, even in her most advanced state, has the ovaries so slightly developed, and their contents so extremely minute, that they generally require the aid of a lens to detect the granular form of the incipient ova. (Exceptional cases occur, though rarely. Mr J. C. Heysham of Carlisle took a female parr in March with the ova largely developed. Other instances are recorded by Mr Yarrell, *British Fishes*, vol. ii., p. 48). The observation is as old as the joint work of Ray and Willoughby (*De Historia Piscium*, Oxon., 1686). In this early, though admirable volume, we have first a description of the salmon, and then of a small fish resembling the young river trout, and which these authors properly regard as identical with the *branlin* of the north of England; in other words, the parr. The passage is headed—"Salmulus, Herefordiæ samlet dictus, Branlino D. Johnson inferiore descripto, ut nobis videtur, idem." "Hujus generis," he adds, "omnes (quod mirum) *mares esse aiunt*. Truttæ persimilis est, at certamen specie differe videtur." We have, then, an enumeration of "Pisces fluviatiles et anadromi è genere truttaceo in Septentrionalibus Angliæ observati à D. Johnson," in the course of which the branlin above named is described in more detail, and some very remarkable peculiarities in its sexual character and constitution are particularized:—"*Branlinus*, nonnullis *fingerins*, *i.e.* digitales, dicti, quia notas seu areolas transversas nigricantes quinque aut sex, veluti tot digitorum vestigia impressa, in lateribus obtinent, cum macula rubra in unaquaque areola. Caudæ sunt forcipatæ, salmonum ritu; *quodque mirum est, omnes mares.* Cum salmonibus, procreandi causa, misceri eos mihi persuasum est. Quum primum enim salmo ovorum editorum congeriem, seu acervum, malis dicere, relinquit, branlinus mox ei incumbit, ovaque (ut verisimile est) spermate suo irrigat et fœcundat; nec alibi unquam inveniuntur *branlini* quam iis in locis quæ salmonis frequentant."

It need scarcely be noted that the preceding observations were not likely to be known to Mr Shaw. But, guided by what he had actually seen occurring in the river beds, he took, in the month of January 1837, a female salmon, weighing fourteen pounds, from her natural spawning place, from whence also he secured a male parr, weighing one and a half ounce. With the milt of the latter he fecundated the ova of the former, and placing the spawn in the small streamlet which acts as the feeder of one of his ponds, he carefully observed its growth, as he had previously that of the salmon spawn impregnated in the ordinary way, and found both the hatching and subsequent growth to correspond in all points with the usual ongoings of nature. This remarkable experiment was repeated with the same results during the winter of 1838, and the parr (taken from the river) which had been used as males were kept alive till spring, when they assumed the migratory dress of young salmon. He then tried a corresponding experiment by impregnating the ova of three adult salmon taken from the river with the milt of three parr bred in confinement, and the results in these cases were the same, both as regards hatching and final growth. The subjects of these trials are now preserved in the museum of the Royal Society of Edinburgh. As these male parr are not mature till well advanced into their second year, and some months after all smolting has ceased, it is clear that, so far as they are concerned, the *biennial* theory is the one that suits them, and which they confirm.

Alleged difference in the habits of male and female.

We have already said that certain observations had recently been made which some regarded as reconciling the opposing views. We have seen them in the *Scotsman* newspaper (of June 6, 1855), from which we make the following extract. The writer begins by stating his belief that, as not unfrequently happens in such discussions, while both parties are in the right, both are also in the wrong. He knows, from observations continued during several years under peculiarly favourable circumstances, that about one-half of the salmon fry produced descend to the sea when one year, and the other half when two years old.

"This important and certainly very singular fact I learned under the following circumstances:—The river Wharfe in Yorkshire was, from forty to fifty years ago, and is yet, for anything I know to the contrary, a sort of experimental breeding-stream for salmon, where the progress and appearance of the young fry may be observed with great accuracy and certainty. Owing to the existence of a very lofty and difficult weir at Wetherby, the salmon can only pass beyond that place when there is a peculiarly favourable concurrence of high floods in autumn; and the consequence has been, that for many years past the fish have succeeded in making their way as far as Harewood and Otley about, on an average, once in five or six years, and the fishermen are therefore enabled to observe what follows the spawning of a few salmon in any particular year without being puzzled and misled by having fry of different years mixed together; from which fact nearly all the uncertainty that has attended this subject in former years has unquestionably arisen. They are thus enabled to state beforehand what sort of salmon fry will be found in the first, second, and third years after spawning has taken place.

"During the first summer they find in the river small parr, which in autumn begin freely to rise at the fly, and are then of two perfectly distinct sizes. In the following spring, generally in April, but varying according to the temperature, the larger of these two species of parr assume the silvery appearance of the smolt, and descend to the sea, leaving behind them all those which were of the second size, and which still retain in perfection the peculiar marking of the parr. These grow considerably during the summer, and in autumn afford, when numerous, sport to the

as it enters on its third year. This is also the case with both the sea trout and the brown trout, nature having so ordered it that the male fish is ready for spawning twelve months before the female—a great secret this, which has puzzled all the writers on the subject, and of which they are ignorant to this day. Every female, on the contrary, deposits her first ova at the close of the third year. You will find your young fish very little larger this month (March) than they were in October last, as neither trout nor salmon grow in winter. Some people will tell you that the young fish are retarded by being kept in the pond during winter. Ask them just to prove it. But whether the salmon fry be retarded in its growth or not, whether it be lean for want of food, or through abundance be grown to double its natural size, it will in either case become a smolt as it enters on its third year."—MS., 5th March 1855.

We may here add that Mr Ramsbottom is very sanguine of an extremely advantageous result from the new process which now prevails, and in the manipulation of which he has been singularly successful. This process consists in capturing (with net) a male and female salmon, both about to spawn, and mingling the milt of the one with the ova of the other. These impregnated ova are then deposited in gravel beds made in imitation of the natural spawning places, a current of pure water being kept constantly in movement over and among them. The chief advantage of the artificial process is its certainty. The natural spawning places are too often torn up, and their contents carried away and so destroyed by sudden floods; but in those artificially constructed, the supply of water is moderated by a sluice, and thus no injury from its violent action can occur.

Alleged difference in the habits of male and female.

juvenile angler. I have caught hundreds of them in and about the month of October, and have almost invariably found them to contain milt, showing that they were male fish. The necessary inference from this fact is, of course, that those who had descended to the sea during the previous spring were females. These male fish, during the following spring, generally about the beginning of March, assume the blue and silvery appearance of the smolt, the change being evidently due to the greater opacity of the scales, which no longer permit the spots and markings of the parr to be visible through them. Another change also takes place in these fish about the same time; their pectoral fins assume a deep blue colour. This change, if I recollect rightly, is not observable in the females when they descend to the sea at the end of the first year.

"When the males have descended the rivers, no salmon fry of any kind are left in the Wharfe, and none will be found there probably for two or three years, when another arrival of the parent fish will cause a repetition of the facts which I have just detailed.

"It was by a careful observation of these facts that the fishermen on the Wharfe were, fifty years ago or more, well acquainted with the natural history of the salmon, when the wildest absurdities were almost universally maintained respecting it in other quarters. It was generally asserted and believed that the smolts which filled the river in the spring were the produce of the spawn deposited during the preceding winter, although that spawn was at the very time still lying in the spawning beds; and Mr Yarrell, in the first edition of his excellent work on British Fishes, was so perplexed by what he had heard on the subject, as to make in two different pages of his book the two utterly inconsistent statements to which I have just referred.

"I may here remark—lest it should be supposed that the two different classes of smolts to which I have just referred were, or might be, the produce of different fish of the salmon kind—that no salmon-mort, sea-trout, or bull-trout, was ever, so far as I know, seen in the Wharfe above Wetherby. None but good strong salmon could, in fact, overcome the difficulties of ascending the river above that place; so that no confusion could possibly arise from a difference of origin.

"Of course I am not so unreasonable as to suppose that my statements on this subject will convince those who have taken up decided opinions to the contrary, but it cannot be difficult to put these statements to a satisfactory test. Let the inmates at the ponds of Stormontfield be carefully examined. No doubt some few will still be left there with the silvery appearance of the smolt. Let one or two of them be examined anatomically to determine their sex. Let the same be done with some of those which now retain—and, if my theory is correct, will be found to retain all the summer—the appearance of parr. Let some portion of these be kept in the ponds until next spring, and it will then be found, if I am not mistaken, that they will assume the silvery appearance, and at the same time the peculiar indigo blue colour of the pectoral fin, which is characteristic of the salmon. A few careful observations directed to test the accuracy of my views on the subject will probably tend to remove an uncertainty which has long and generally prevailed; in which case I shall be extremely glad to have contributed in any degree, however trifling, to the attainment of such a desirable object."—Piscator.

Advantages of the breeding system.

This statement is worthy of consideration. It certainly accords with, if it does not account for, the anomaly already noticed, of the number of mature male parr, and the great rarity of females in the same condition. No doubt Dr Heysham informs us, that he has at different times and seasons examined 395 parr (or samlets, as they are called at Carlisle), and found 199 males, and 196 females. But this may have been when they were intermingled; or he may have counted many females at one time, and many males at another. It does not, however, reconcile the contending theorists. We cannot suppose that certain salmon produce only male ova, and others only female, yet something of this kind must be assumed, to account for Mr Shaw's specimens almost all requiring two years to *smolt*, while Mr Young's never needed more than one. How could the former chance to be almost all males, and the latter almost all females? Another odd circumstance will result from this new view, viz., that no pair of grilse, of different sexes, can ever be of the same age. A brood of young salmon are hatched, say in the spring of 1853. In that of 1854 all the females become smolts, descend to the sea, and return from it as grilse in summer. But their male companions abide for two years in the river, and so have no chance of being grilse till the summer of 1855. On the other hand, the actual male grilse of 1854 must (according to the theory) have been bred in 1852, and so are necessarily a year older than those with which they pair. So also must there be a difference of at least a year in the age of all salmon (as such) of different sexes. A female fish hatched in the spring of 1853 becomes a grilse in the summer of 1854, but all the males of her early acquaintance must wait for their conversion until the summer of 1855, by which time she has herself become a salmon. Her brothers, no doubt, become salmon in 1856, and they are then all in the same state, and also actually of the same age, although the females have the advantage of being in their second year as salmon, while the males (having lost a year in fresh water) are only in their first. Of course there are both male and female smolts descending together to the sea during each and every spring, but according to this new notion the former are two-year-old, and the latter only one. Let this point be henceforward looked to carefully by anglers, and all others who have opportunities of observation. The whole subject of the age of smolts has now become of high importance in an economical point of view, to those who raise the fish in ponds. As a consequence of the annual theory (if founded on fact) being reduced to practice, we shall have it in our power to produce good marketable grilse in fifteen or sixteen months from the hatching of the ova, while, according to the biennial view, that advantage will not be obtained until the lapse of about two years and a quarter. It is like the sudden conversion of "gimmers" into four-year-old mutton, a mutation which the sheep-farmer would fondly see.[1]

Having now endeavoured to explain the prevailing opinions regarding parr and smolts, we shall proceed to consider briefly the third stage of a salmon's life, that which

[1] We are indebted to Mr Robert Buist of Perth for giving us recent information regarding the condition of the parr and smolts of the Stormontfield ponds. It appears that although so obvious a change was observable among the majority by the end of May that they were allowed to take their departure into the river, a great number of a smaller size neither exhibited the same external change nor a like willingness to leave the pond. There they still abide as *parr*, no doubt waiting for the spring of the ensuing year. Some hundred thousand are supposed to have been successfully hatched, and of these Mr Buist calculates that about 130,000 took their departure seawards. Of these about 1300 were marked by cutting off the small dorsal or adipose fin; and several of them have been already captured on their return as *grilse*. The hope is entertained that for every marked grilse that returns, 100 others (also original inmates of the pond) return with it. It may not be easy to ascertain the actual proportion which still remain in the pond. If the original number brought up there amounted to 300,000, then the exodus consisted of not one half. "*One third*," says the Perthshire Courier of 26th July 1855, "of the original stock are still in the pond, and although the sluice has never been closed since it was first opened in May, they manifest no desire whatever to leave it. In point of fact, with perfectly free means of egress, not one of them has left the pond since the general migration ceased at 7th June last. Thus, while one portion of the same hatching are being captured in the river,

Conversion of smolts into grilse.

immediately precedes its adult state—to wit, the condition of grilse. So salubrious is the sea, so enlarging the influence of its wide domain, that no sooner has a smolt of a very few ounces in weight been launched into that vast abyss than it suddenly expands in growth, even as the children of the Anakim. In a couple of months it will then weigh more pounds than it previously did ounces. This great and rapid growth seems to depend entirely upon what the fish obtains in salt water, and the longer it remains there the larger it becomes. The chief run of grilse into the rivers does not take place till summer is well advanced. Very small grilse are sometimes caught in early spring. They cannot then be otherwise than small, because they have chosen to return to the rivers in a few weeks after they had left them as smolts. Larger grilse, but still of small dimensions, are caught in early summer, and they thus increase in size in proportion to the length of their sojourn in the sea. Of course, a smaller grilse may be sometimes caught in August, and a larger one in July, but this quite conforms to the general principle which regulates their growth—the latter having been longest in the sea, as one smolt may migrate early in April, and another not till the beginning of June, some being sooner ready for their journey, because earlier hatched. There is no proof of anything like a lengthened and continuous succession in the migratory movements of smolts. These movements may be in some measure modified by the temperature of the preceding season, and so extend, more or less, over several weeks in spring. Thus, also, the size of grilse and the periods of their appearance vary, but the great mass begin to ascend about the middle of July, by which time they have been nearly three months in the sea. The largest grilse are found in autumn, and the least in spring. We regard this as a sufficient proof that the *smolting* process ceases soon after the commencement of summer. If any parr became smolts in autumn (as some suppose, thereby seeking to account for the continuance of the middle-sized kind in the rivers after spring), and made only a short sojourn in the sea, then we should have small grilse coming up in winter, which is not the case; or if they remained in the sea for a longer time, then we should have large grilse in spring, which is equally well known to be not the fact.[1]

That smolts become by conversion grilse has been satisfactorily demonstrated by Mr Andrew Young. In the spring of 1837 he marked a number of the former, just as they were about to descend towards the sea, by making a perforation in the caudal fin by means of a small pair of nipping irons constructed for the purpose, and in the course of the season he re-captured a considerable number on their return to the rivers, all in the state of grilse, and varying from three to eight pounds, "according to the time which had elapsed since their first departure from the fresh water, or, in other words, the length of their sojourn in the sea." In the spring of 1842 he likewise marked many descending smolts, by clipping off the small ray-less protuberance upon the dorsal line, called the adipose fin. In the course of the ensuing June and July he caught them coming up the river as grilse, bearing his peculiar mark, and agreeing with those of 1837, both in respect to size and the relation which that size bore to the lapse of time.

Note of Smolts marked in the river Shin, and recaptured as grilse on their first ascent from the sea.[2]

Period of marking as smolts.	Period of recapture as grilse.	Weight when recaptured.
1842. April and May.	1842. June 28.	4 lb.
... ...	... July 15.	5 lb.
... ...	... ... 15.	5 lb.
... ...	... ... 25.	7 lb.
... ...	... ... 25.	5 lb.
... ...	... ... 30.	3½ lb.[3]

As the growth of grilse is dependent on the sea, fish in that stage, though necessarily younger, may be of greater dimensions than adult salmon, and for the following reasons:—

beautifully grown grilses of four and twenty inches in length, another portion is still enjoying the shelter of the pond, tiny creatures, none of them more than three or four inches long."

It is impossible at present to say what the effect of superabundant feeding may be in hastening the process of development. If scattering quantities of boiled and grated bullock's liver several times a-day into the ponds, has produced an earlier *smolting*, then the triumph of artificial rearing of salmon stock is all the greater, and the more assiduously should the process be put in practice. We certainly noticed and pointed out to others, during our examination of the ponds, that all those parr which continued to swarm in the small streamlet which flowed from the hatching troughs into the large feeding pond, were much smaller and otherwise less mature than such as swam and fed in the expanded piece of water, in the comparative stillness and extent of which they had no doubt a more ample supply of food, and a greater range of ground, than what were enjoyed by the inmates of the running water. We know from observation that the increased rate of growth in young trout, when their native streamlet has been converted by damming into a large pond, is sudden and extraordinary; and it is possible that the constitutional change which parr undergo in their natural conversion into smolts, may be induced at an earlier period by artificial feeding. Mr Shaw's specimens, so few of which smolted when a year old, were left to their own resources. In the meantime, many considerate people view the combatants in this field as they would the knights of old, who disputed from opposite sides whether the face of the shield was of gold or silver. There are now abundance of undoubted parr still in the pond, though far advanced into their second year, while it seems just as certain that a great multitude took their departure two or three months ago as smolts, and are now returning, there is every reason to believe, as grilse. "So," says Mr Buist, "Young and Shaw will be both right. Young's smolts are off, Shaw's parr remain. What can be the cause?"

The following is a note of the number, weight, and sex of the marked grilse taken in the Tay up to the 4th of August of the same season (1855) as that in which they were marked as smolts. July 7, 3½ lb., a female, taken near the junction of the Earn and Tay. July 20, 5½ lb., likewise a female, taken four miles below Perth. July 24, 5 lb., a male, taken fourteen miles below Perth. July 30, 7½ lb., a male, taken at Perth. August 1, 7½ lb., a male, taken at Perth. August 4, 6 lb., taken near Perth; also one of 7 lb., taken below Elcho Castle, and two others reported, but not transmitted for examination. The sex of these last four was not stated. We may add that our recent observations and reports do not confirm the idea that the female parr become smolts and migrate in one season, and the male parr in another. We now find both sexes among the midsummer parr, the males being sexually developed, the females in that respect immature, that is, with the ovaries but scarcely formed, and only minutely granular in their contents.

[1] Mr Young states that the majority of grilse remain in the sea only for about a couple of months, and he has shown that the longer they remain there the larger they become. He admits that the smallest are caught in spring and early summer, the largest towards the close of the latter, and in autumn. Now if the majority of smolts soon return from the sea, and all that abide in it for a lengthened time become large grilse, what is the result or produce of such smolts, as, according to Mr Young's view, descend to the sea in October? If they return soon they would necessarily be small grilse, if late, large ones; but no small grilse ascend in winter, and no large ones in spring, although that would unavoidably happen, in accordance with his supposition of an autumnal smolting, if that supposition were correct.

[2] See a paper by Mr Young, *On the Growth of Grilse and Salmon*, in the *Transactions of the Royal Society of Edinburgh*, vol. xv.

[3] Our object, in regard to the important points now under discussion, being to ascertain and communicate the truth, we have always great pleasure in receiving information or opinions from people of practical experience. We believe in the rapid transmutation of smolts into grilse as recorded by Mr Young, and confirmed by the corresponding changes undergone by the sea-trout of the Nith (*Salmo trutta*), where their smolts are as rapidly converted into herlings, which are the grilse of that minor species, as shown by Mr Shaw. But we shall here note, as not conforming with those views, the sentiments of Mr Paulin of Berwick, agent for the shipping company there, to whom we are otherwise indebted for some valuable statistical information concerning the salmon fisheries of the Tweed.

"I observe at Perth there is a strong belief that the smolts of this season, which have just lately gone to the sea, will return as grilse

Conversion of grilse into salmon.

One grilse leaves the sea early and ascends into the river, where his growth gains no increase. He descends after spawning, and makes his second return to the river, in early spring, a small but adult salmon. But he may not have been more than six weeks each time, that is, three months altogether in the sea. Another grilse abides continuously in the salt water all summer, and having gone down early (as a smolt) and ascended late, he may weigh 8 or 9 pounds when he goes up the river, being, as a large grilse, heavier than a small salmon. Grilse, then, ascend the rivers, and breed there when their time comes, after the manner of adult salmon. They re-descend to the sea in like manner towards the close of winter, or in early spring, undergoing the same process of deterioration by long residence in the river, and of restoration through marine agency, and on their second return to the fresh waters they are salmon, properly so called.

This conversion of grilse into salmon had been known from an early period of the fish's history. The rate of progress has more recently been shown by Mr Young. He commenced marking grilse as far back as 1837, and has frequently done so since. We shall here record only the result of two successive seasons. In the spring of 1841 he marked a number of spawned grilse of four pounds weight soon after the conclusion of the spawning period, by putting a peculiarly twisted piece of wire through the dorsal fin. They were immediately thrown into the river, and of course disappeared, making their way downwards with other spawned fish towards the sea. In the course of the ensuing summer he recaptured several of them, and found that they had grown in the short period of four or five months into beautiful full-formed salmon, varying from 9 to 14 lb. in weight, the difference depending on the length of their respective sojourn in the sea. In January 1842 he repeated the same process of marking four-pound grilse which had spawned, and were therefore about to seek the sea; but instead of placing the wire in the back fin, he this year fixed it in the upper lobe of the tail. On their return from the sea he caught many of these quondam grilse as before. The following table, which we owe to Mr Young, illustrates the rate of growth.

List of grilse marked after having spawned, and recaptured as salmon, on their second ascent from the sea.

Period of marking.	Period of recapture.	Weight when marked.	Weight when recaptured.
1841. Feb. 18.	1841. June 23.	4 lb.	9 lb.
... 18.	... 23.	4 lb.	11 lb.
... 18.	... 25.	4 lb.	9 lb.
... 18.	... 25.	4 lb.	10 lb.
... 18.	July 27.	4 lb.	13 lb.

Jan. 29.	... 11.	4 lb.	12 lb.

Size of adult salmon.

We commenced the preliminary portion of our present treatise by an indication of this fine fish in its parental state, and we now complete the somewhat complicated circle by coming round to the point from which we started. There is no proof before us that salmon, after once fairly ascending a river, however early in the season that ascent may be, ever return seawards that same summer. They seem to abide continuously in the rivers till the breeding season commences on the occurrence of cold weather, and do not descend again till they have spawned. The following bears on this important point. Mr Stephen stated, in his evidence before a committee of the House of Commons, that "our cruives on the river Don are so constructed, that salmon of ten pounds weight can at all times go up, but none can descend past the cruives. We fish generally in the pool above the cruives; and if the unspawned salmon returned again down the river, we would undoubtedly catch them there, which is never the case. They are never seen to descend the river except as kelts after having spawned." The after conditions of the adult salmon life being beset by difficulties which no man can number, its ultimate term of existence, and the size to which it might eventually attain, are as unknown quantities, or at least can only be approximately inferred from casual cases. Such individuals as for several seasons succeed in avoiding the deadly and deceptive chambers of the bag and stake nets (*Lasciate ogni speranza, voi, che 'ntrate*), and escape, moreover, the sweeping meshes of the boatmen, the wily prison of the darksome cruives, the angler's gaudy lure, and the poacher's relentless leister, will no doubt continue to increase from year to year. But such are now the multiplicity and perfection of our various fisheries, and so great the facilities for preserving and transmitting this princely and highly-prized species from even our far northern rivers, to the luxurious cities of more southern districts, that it may be greatly doubted whether any British salmon ever attains to a good old age, or dies a natural death. We therefore possess but few data from which to judge of either their natural term of life, or their final dimensions. They are still occasionally, though rarely, killed of the weight of forty, or even fifty pounds. But these are giants of their race. We know, however, that a few years ago, in the then comparatively slightly-fished rivers of Norway, salmon of those sizes were by no means uncommon; and it is authentically recorded that even in this country, and in our own days, a female fish came into the possession of Mr Groves of Bond Street, which weighed 83 lb. Pennant had previously recorded one of 74. We shall here note one or two cases of the ascertained increase of size in adult salmon. In the year 1841 Mr Young marked some spawned salmon by means of copper wire. One of them which had been marked on the 4th of March, when it weighed 12 lb., was recaptured on its return from the sea, on the 16th of July, weighing 18 lb. He found that the majority of his marked fish did not continue absent more than two months, and his experiments not only demonstrated this fact, but another of great consequence to the breeder of salmon—

in July and August next. From my own experience I think this will be found not to be the case, although among the fishermen it was the universal belief only a few years ago. In *May* 1851 there were a great many smolts in the Tweed marked by a silver wire being put in their tails. At this time they could not be above two or three ounces in weight, and the first of them that was caught was in *August* 1852, when it weighed four pounds four ounces. There were several others taken during the same season, some with the wire in the tail, and others with the mark of the wire worn out, so that the experiment was very satisfactorily proved, and one of the specimens is preserved in spirits in the Tweed Commissioners' office until this day. It would appear, therefore, that grilse are the smolts of the *second year*, but to what part of the sea they retire during the intermediate time is yet a mystery.

The rapid growth of the grilse has been argued as a reason for the belief that they are smolts of the *first* year. When they first make their appearance in April or May, they are certainly found to be less than two pounds in weight, and before the end of the season (15th October) many of them weigh perhaps as much as seven or eight pounds; but taking the average of seven years (1845–1851) I found the growth to be as follows:—

Average Weight of Tweed Grilse—June, 3 lb. 3 oz.; July, 4 lb. 7¾ oz.; August, 5 lb. 2½ oz.; September, 5 lb. 10½ oz.; October, 6 lb. 11 oz.

Now it is almost impossible to believe that a fish weighing only two or three ounces in April or May should increase in its growth with such rapidity as to weigh fifty-five ounces in June (which would be twenty times its weight in six or eight weeks), while the same fish, weighing 3½ pounds in June, does not double its weight in the next four months ensuing."—MS., 29th June 1855.

Varieties of salmon.

that these fish invariably (if permitted so to do) return to the rivers in which they have been bred. Mr Young's position was peculiar in the opportunities which it afforded for the ascertainment of this feature in their history. Although five good rivers fall into the estuary, or central course of the Oikel, the marked fish were always found again, each in the particular river in which its badge had been imposed; and although all these rivers fall into the same estuary at different places, and the fish must come up promiscuously together through the briny waters of the lower portion for twenty miles, each river has its own peculiar race, and each race always finds out and enters its own river.

"The first of these rivers," says Mr Young, referring to the upper portions of the so-called Dornoch Frith, "that falls into the estuary, has a run of well-shaped salmon, whose average weight is about 10 lb. The second has strong, coarse-scaled, rather long to be well shaped, but very hardy salmon, whose average weight is about 17 lb. The third has a middling-shaped fish, whose average is about 9 lb. The fourth river has long ill-shaped salmon, averaging about 8 lb. And the fifth river, though the smallest of the five, has fine-shaped fish, averaging fully 14 lb.; and although the fish of all these rivers mix together, and all travel together on the common road to the sea, feed there promiscuously on the common feeding ground, and then return by the same common path, each party finds out its own home with the greatest precision, for scarcely ever is one of them seen in its neighbour's possessions. This precision is yet a mystery, among many others; for although we see rivers of different temperature arising from the size or situation of lakes from which they are fed, we find others of the same situation and temperature, and yet the fish must know a distinctive quality that leads them to their own native streams. It is true that salmon have their summer and winter courses for travelling in the same river, and that is also kept with the most exact precision; for in winter, and up to the first of May, salmon invariably run up the north side of rivers, whereas from 1st May to November they run on the south side."[1]

The most remarkable instance of rapid return, with extraordinary increase of growth, of any salmon we have ever heard of, is that recorded by the Duke of Atholl. A fine fresh-run fish, much exceeding the ordinary size, was transmitted to his Grace from the lower portion of the river Tay. It bore the badge of "No. 129." "On referring to my journal," observes the Duke, "I find that I caught this fish as a kelt this year on the 31st of March with the rod, about two miles above Dunkeld Bridge, at which time it weighed exactly 10 lb.; so that in the short period of *five weeks and two days* it had gained the incredible increase of 11 *lb. and a quarter*, for when weighed here on its arrival, it was 21 lb. and a quarter."[2]

That all the individuals of the fish commonly called the salmon (*Salmo salar*) belong to one and the same species, we entertain no doubt, although the *variations* of that species are considerable. Whether these are original conformations, or the result of local influences, it would be hard to say. That the fish of each river naturally desire to return to that river is also an ascertained fact; and it is by taking advantage of the facilities afforded by that strong and steady instinct that the age and growth, within a certain period, of individual salmon (and so approximately of the whole) have been ascertained. In one river a large breed of salmon is found—so large as to average nearly eighteen pounds in weight—while in another almost adjoining, that is, in the same district, the breed is so small as not to exceed an average of seven pounds. In some rivers the salmon, even in their best condition, are long and lank; in others broad and short, so much so, that when cut up their transverse section is almost circular. In one river we may find all the salmon nearly straight along the dorsal line, while in others they are rounded or hog-backed. In some places all these fish have large and clumsy heads; in others that part is small and neat. Even in the very variable character of spots and scales, there is often an obvious, that is, a permanent or abiding difference. Mr Fraser has stated that in the Ness and its branches there are three sorts or varieties of salmon—one with three rows of spots, one with four, and one with five, exclusive of the difference in shape and size. But it is the difference in the river that generally manifests the difference in external aspect, and this, when dimensions are concerned, is still a mystery. All salmon gain their growth in the sea, and the same marine food (whatever it consists of) is open alike to the natives of all rivers. The waters which flow through the Kyle of Sutherland, and, becoming confluent with the Carron, discharge themselves into the head waters of the estuary of Dornoch, near Bonar Bridge, have each, as we have said, a distinguishable kind of salmon; and those which eventually enter the Shin are twice the size of most of the others. Yet they must seek the same parts of the sea by the same channel, and while *parr*, or during their early period of fresh-water growth, seem as well fed in one river as in another. As the increase of growth undoubtedly depends on sea-feeding, it is less easy to understand the cause of difference when the feeding is the same. Why has a Shin parr the power of becoming a much larger salmon than one from the Oikel? Or how have the Shin salmon sprung up into a large race under apparently the same physical conditions as those with which, in the sea and estuary, they are intermingled? If the growth was in the river, then we could comprehend how great differences in size might result from existing differences in the breadth and depth, as feeding grounds, of our multitudinous and very varied streams. But as it is known that fresh waters have nothing to do with the growth of salmon after they have ceased to be either parr or smolts, and the fish of one river cannot appropriate to themselves any marine food distinct or different from that which is also at the option of all the others, we find it more difficult to understand how a large average size of fish should result from one river, and a small average size from another near it. But so it is.

Before proceeding to take a view of the commercial bearings of the subject, and the modes by which these fish are captured, we shall inquire briefly into the laws which regulate that capture, and constitute the legal rights of the captors.

[1] *The Natural History and Habits of the Salmon*, London, 1854.

[2] In regard to this marking of grilse and salmon, the following apprehension has sometimes come into our mind. It is easy to suppose an individual of high rank, great wealth, and large public spirit, taking pains to mark certain fish, and record their re-capture after a certain time. To secure or induce their restoration when caught by others in some far-distant portion of the river, a reward is probably promised (besides the market value) to whoever takes and delivers up the marked fish on its re-ascent from the sea. If the identical fish is re-produced, and the times and weights compared, of course the rate of growth is correctly ascertained, and may be relied on as a fact. But it is also quite as easy to suppose an individual of low rank, no wealth, and as little public spirit, catching, by leister or otherwise, a 10-lb. marked kelt on its way downwards. He removes the mark (kippers the kelt), and in due time attaches it to a fresh-run fish of 17 lb. 8 oz., which he carries as quickly as he can to some palatial residence where rich men congregate. The fact is easily ascertained that the latter fish now weighs 7½ lb. more than did the former when laid in the balance; but is it equally an ascertained fact that the original kelt has really gained that increase in a given time? These observations do not apply to such practical experiments as Mr Young's, conducted from first to last by the same individual, seeing with his own eyes, offering no reward to any one, and having the great advantage of the entire control of a short though productive river. Mr Young can keep the Shin, as it were, under lock and key.

Regulating laws of salmon-fisheries.

By the law of Scotland salmon-fisheries are regarded as *inter regalia*, and the result of this is that they are not carried by a general grant of the lands and their appurtenants in any grant holding of the crown (which is the way in which all land rights are held in Scotland ultimately), but must be the subject of special grant, either express or implied. The subject of the former is, where a charter is given by the crown expressly *cum piscationibus salmonum*. An implied grant is where the words used may be simply *cum piscationibus*, without any addition of *salmonum*, or where the grant is of a barony. In the former of these two later cases, if the salmon-fishing has been possessed by what is accepted as a legal mode of possession—not simply fishing with the rod, which is not so regarded, but by some greater, we shall not say nobler, exercise of the right of fishing;—if the salmon-fishing has been so possessed under a grant *cum piscationibus* simply, the salmon-fishing will be carried. With respect to the grant of a barony, it is doubtful whether a mere grant with possession gives prescriptive right. Lord Rutherfurd has stated his opinion that the grant of a barony, followed by possession of salmon-fishing, exercised by some higher species of possession than that of the rod, would carry the grant of salmon-fishing also. Scotch salmon-fishings do not require any parliamentary ratification, and the grants are equally good at whatever period they have been made. There is no reason why the crown should not now make a grant of salmon-fishing which shall be quite effectual to the grantee, provided, of course, it does not interfere with any previous grant already made by the crown, whether that previous grant is expressed or implied, and if in the latter case it has been made effectual by prescriptive possession. To establish a right in Scotland the period of prescription is forty years; but the possession for that time, to establish the prescriptive right, must proceed upon what is termed a sufficient title. It is a sufficient title, in the case of salmon-fishing, if there has been continuous and uninterrupted possession for forty years following the grant simply *cum piscationibus*, or the grant of a barony. Salmon-fisheries, in Scotland, belong to the crown by beneficial title, and not merely in trust for the public, after the manner of highways. Thus all grants of salmon-fishings hitherto made by the crown have been for a consideration, although, through favour to the subject, the payment may be made illusory, as a penny yearly, or the blast of a horn. This right of salmon-fishing has been very extensively granted by the crown along the shores of navigable rivers and on the sea-coasts, and may be quite distinct from the possession of the land upon the banks or shore. Thus the grant of a salmon-fishing may not be the grant of the shore on either side of the river—the party may not be the grantee of the shores of the estuary, or the coast of the sea. These regal rights were not constituted by any acts of the Scotch parliament, but are part of the immemorial law of Scotland.

There are three natural positions in regard to which salmon-fishings may be the subject of royal grant in Scotland. First, they may be simply upon the sea-shore, and in the sea, and at such a distance from the mouth of a river that they cannot be considered as part and parcel of any other fishing, either of river or estuary. These being less special than the others, and impinging upon the open or public sea, have been less jealously regarded, and there is no doubt that many shore proprietors, with no deputed right from the crown, exercise that right erroneously, though to their own advantage. Secondly, these salmon-fishings (in this case often of great value) may be in what are called estuaries, a somewhat ambiguous term, differently construed at different times and places, but the fisheries of which the ancient Scotch acts of parliament define as being "in fresche watteris, quhar the see fillis and ebbis," and "upon sand and schauldes far within the water." The third position in which salmon-fishings may be carried on is in pure rivers, where the water is always fresh, and always descending.

As there is a prohibition by statute of all fixed machinery for the fishing of salmon in the "rivers" and "waters" of Scotland, where the sea ebbs and flows, disputes have not seldom arisen (from the difficulty of applying the principle to special localities) between the seaward proprietors who desire to extend the region of stake-nets riverwards, and the upper proprietors who equally desire to drive them downwards. It has been held, according to Mr Bell—1st, that the prohibition extends to all rivers and estuaries to the fullest extent to which the sea ebbs and flows, and down to the *fauces terræ* at the mouth of the firth, and the sands dry at low water, as well as in the channel; 2d, that it does not comprehend the proper shores of the sea; 3d, that stake-nets are prohibited in the land-locked estuary of a river, being the intermediate space between what is strictly the river and strictly the sea, but where the river and fresh water still exists with predominating influence; and that they cannot lawfully be placed either in the channel of such river or estuary, or on sands which are left dry by the ebbing of the sea; and, 4th, there is an exception in the statute of 1563 (prohibiting machinery where the sea ebbs and flows), "that it shall not be extended to the cruives and zairs being upon the water of Solway," which is the subject of particular regulation, being a border fishery.

The protection and encouragement of the breed of salmon in the rivers of Scotland appear to have engaged the attention of the legislature from a very ancient period, and numerous enactments have been passed from time to time. Some of these related exclusively to the *regulation* of the cruives or other engines in which the fish were caught, without reference to the localities in which they might be placed; and it seems not improbable that originally this matter of regulation was the thing chiefly in view. But in progress of time, when the importance of the fisheries began to be felt and acknowledged as a great branch of international wealth and source of subsistence, other laws were enacted, not merely to regulate the cruives and zairs, but also to prohibit them absolutely in certain situations where their existence was ascertained to be adverse to the important object of maintaining the breed of fish. With this purpose in view, a numerous series of enactments was passed from the reign of James I. down to the union of the two kingdoms; and in one respect those enactments proceed invariably on the same principle. While they permit cruives and other kinds of fixed machinery in the *fresh* waters of rivers to which the tide does not extend (subject to certain regulations and conditions), they absolutely prohibit all such machinery below that point, or within the influence of the tide. They prohibit it "in fresche watteris, quhar the see fillis and ebbis,"—"in watteris that fillis and ebbis,"—"in rivers that has course to the sea," and "within the fludemark of the sea,"—"in waters quhair the sea fillis and ebbis,"—"within salt watteris, quhar the sea ebbis and flowis,"—"within salt waters that ebbis and flowis,"—"upon sands and schauldes far within the water," and in general "upon the water sandis."

An estuary is admitted to be different from a river, and the difference is constituted by a certain intermingling of marine features. The ascertainment of the upper portion of an estuary, where it is gradually lost in the river, is, we presume, a point not mooted in any stake-net question, which rather seeks to determine the lower limit of the estuary, where the remnants of its fresh-water characters fade away, and its marine ones increase, to the eventual entire exclusion of the others. It is clear that where a river discharges itself upon an open coast at once into the sea, its independent character is almost instantaneously destroyed, without the intervention of any estuary or other debateable region. The ocean waters are so boundless and redundant,

Debateable waters.

those of the river so narrow and restricted, that no effect is produced upon the former by the latter. This is the case with one of our noblest streams at Tweedmouth, where we have river and sea, yet no estuary. But where the river, as in the instances of Tay and Oikel, has to work its way through "sands and schauldes," and along the centre of what, in comparison with the open coast, may be called an inland valley, the basin of an extensive watershed on either side, and which receives at its head a confluence of rivers flowing from remote and ramified upland districts, the position of affairs, as between salt and fresh water, becomes entirely changed. There we have a small, confined, and shallow sea, crossing, it may be, an obstructing bar or other sand-bank, its force during flow being exhausted by having to expand over wastes of mud and shoals of gravel; its saltness decreased, and ere long destroyed, by the influence of the multitudinous streams and rivers which rush ceaselessly by night and day into its bed (to say nothing of an extensive though unobservable drainage from the land); and the sea itself, such as it is, allowed to advance so far inland merely by the flatness of the upper portion of the landward basin.

The term estuary, though not seldom very vaguely applied, is always intended to signify such waters as lie between the undoubted fresh-water river and the firth or sea. An arm of the sea (such as Loch Fine, Loch Sunart, and others, on our western shores) is a lengthened body of marine water entering inland, and varying in height with the state of the tide as relates to ebb and flow, but never withdrawing itself from its retentive basin, the productions of which are essentially marine. The purest of all sea water is of course that found at a great distance from land, where neither animal nor vegetable productions are at all abundant, and where even birds and fishes, each and all of whom are "winged messengers" in their way, are much less numerous than nearer shore. The closer, within certain limits, we approach the coasts, the more abundant are marine productions. But as we ascend firths, and enter the mingled waters of estuaries and the fresh ones of rivers, these gradually diminish, and eventually disappear.

It has been argued that the ascertainment by philosophical investigation of some single great physical fact, such as the precise point inland at which the tide is always either ebbing or flowing, would and ought to determine the disputed question, as to where the sea ends and the estuary commences. This, of course, would be where the fresh water of the river meets the salt water of the sea at lowest ebb; a theoretical test not likely to have been much in the minds of Scotch barons in the days of Robert the Bruce, and which, if applied in our own days, would destroy at least the majority of the net-and-coble salmon-fishings throughout the country. Mr James Jardine, our eminent civil engineer, was the first to point out and ascertain this test for determining where a river ends and a firth begins, having been employed in that investigation in 1810, in the great Tay case, the Duke of Atholl *v.* the Honourable William Maule. Mr Jardine gave in a report, in which he professed his object to be, to inquire into such circumstances in regard to the localities of the Tay, "as might seem of importance in determining the common boundary of the firth and river;" and among the various points which he states as ascertained are the following:—First, that of the common section of the mean surface of the sea and river, which he determined to be at a place called Friarton; secondly, the line in the firth above which the sea-ware ceases to grow; and, thirdly, the point of the lowest ebb in the channel of the river. That part of the report which relates to the last-mentioned point, is entitled "Of the highest point at which the sea is always either ebbing or flowing," and under this head we have as follows:—"From a series of observations on more than fifteen tides, it was found that the highest point at which the medium tide was always either ebbing or flowing, was immediately above the confluence of the Earn and Tay. This determination, however, must be considered as less accurate than could be wished, on account of the advanced season of the year in which the observations were made." The report then concludes with a general summary. "Having thus examined in detail the several circumstances proposed, I am led, in estimating their comparative importance for determining the common boundary of the river and firth of Tay, to lay the greatest stress on the three last, particularly on that which determines the highest point at which the tide is continually ebbing and flowing. This boundary cannot, I think, be placed higher than Friarton, where the common section of the mean surfaces of the sea and river has been shown to take place; nor can it be lower than the line which stretches across the firth from Errol-Dyke to the stone above Bambreich Castle, where the sea-ware ceases to grow. It appears to me, therefore, that the confluence of the Earn and Tay is the proper place of the boundary in question, since it is nearly the mean between the limits above mentioned; is the commencement of the character of a river, as indicated by the appearance of gravel; and, lastly, is the highest point or place where the medium tide is continually ebbing or flowing." To this Professor Playfair added a brief opinion, in which he states, that "the highest point in the river where the tide is continually either ebbing or flowing, furnishes, in my opinion, the best criterion for ascertaining where the firth ends and the river begins; it is a rule applicable in all cases, and much more definite than what could be deduced from the mean level of the sea, the saltness of the water, or the growth of sea-weed,—all of which, however, Mr Jardine has determined in the present case with all the accuracy of which their nature would admit. This criterion, therefore, which I believe to be new, is valuable, not only as applicable to the present and all similar questions, but as establishing an important fact in the natural history of rivers."

We believe that no single character or criterion can be adopted in the solution of this question as it bears upon salmon-fishing. That referred to, however interesting as a question in hydrology, or the geography of physics, is certainly not the test of the statutes, and their construction in accordance with it would, in most cases, exclude the greater portion of the space which falls within their meaning and consequent protection. The adoption of what is called the *medium level* of the sea would of course be still worse. That level, for example, cuts the *surface* of the river Tay at *Friarton*, and the *bottom* at the Townford, and so would carry the fixed engines above the best regions of the net-and-coble. The same point, in relation to the estuary of the Oikel, would carry the sea several miles above Bonar-Bridge, where the water is fresh even at high tide, and where at ebb the river descends with all the rapidity, and a thousand times the strength, of a mountain torrent. We believe that each estuary must be tried upon its own merits, so greatly do those inland reaches differ in their natural character and conditions. The sea is a great intruder, and is sure to find its own level in spite of all opposing obstacles. If, in pursuit of such level, it flows over vast hollow basins, and into lengthened ravines of great depth, scooped out into the very bosom of the loftiest hills, as is the case in all our western lochs (Sunart, Nevish, Hourn, Alsh, Torridon, Broom, Laxford, &c.), it necessarily abides there continuously and for ever, in the ratio of the excess of depth over the difference between high and low water; so that if the actual depth of these great sea-lakes is one, two, or three hundred feet, a difference of 12 or 16 feet (consequent on the rise and fall of tide) makes really no alteration upon them whatever. They are essentially the same at low-water as at high, and are arms or branches of the sea, not estuaries. Though goodly streams may pour into them abundance of

Debateable waters.

sweet water, the general watershed above and around them is quite insufficient to deprive them of their strictly briny attributes, and their steep cavernous shores are haunted habitually by lobsters and other truly marine creatures, and visited periodically by millions of herrings, which, as in the branching lochs of Shieldag and Torridon, or the still deeper indentations of lochs Dhu and Cul, between Assynt and Edderachillis, swim up in glittering hordes to the very bases of the inmost hills. It is this character of depth, and consequently of *abiding quantity*, which in truth distinguishes the western sea-lochs from the so-called firths upon the eastern side of Scotland.

It is equally clear that fresh water, being specifically lighter than salt, can never so plunge beneath a depth of sea as to make and keep an *alveus fluminis*, or maintain any permanent or influential character of its own, after meeting a great mass of *abiding* sea-water. It reaches at once its final bourne—has no struggles to endure with sands and shaulds, but sinks into immediate insignificance among the great sea-waters. The consequence is, you may have herrings, haddocks, codling, skate, mackerel, and many other fishes, up to the very inmost parts of these saline branches, where also lobsters and other crustacea, with oysters, and more of the testaceous class, rejoice respectively in holes or flatter scalps, over which fresh water cannot flow.

But if the sea far below its line of lowest ebb is extremely shallow and of small extent, if it be so broken up by "sands and shauldes far within the water," and encompassed by a broad continuous stretch of gravel and slimy or alluvial sand, on either side, so as to present at low water an appearance along shore as if there "was no more sea;" these are characters different from those just alluded to, and which form most important elements in estimating the true attributes of a particular locality, of which the essential features result from differences in depth and quantity. Most of the exposed space may (and indeed must) be below the medium level of the ocean, but this is not the question, which, in truth, does not concern levels. That question we conceive mainly to be, the proportional power and influence of the salt water over the fresh, or *vice versa*, because by that power, one way or other, are marine or fresh water productions respectively encouraged or destroyed. Now, it seems clear, that if the sea in its usual state at low water, is merely commingled with and partly overcome by the *linum fluminis* which pervades its centre, and constitutes its main channel; and even after the completion of its upward flow, has still spread its shallow waters only over the bare and broad expansions, before mentioned, upon either side; if the actual quantity of fresh water poured in above and around remains the same, the *proportional* quantity of that water must depend upon the mass of sea with which it is required to mingle; or, in other words, the solution of the question, "Sea or estuary?" must depend almost entirely upon the depth of the trough into which the river falls.

The machinery permitted in pure rivers or streams of unmixed fresh water, in which the sea does not ebb or flow, is regulated on the principle, that there shall be a sufficient passage left for the descent of the young fry, and, to a certain extent, for the ascent of the full-grown fish. The hecks, or open frame-work of all cruives, must be pulled up every Saturday evening during the fishing season at 6 o'clock, and the space remain open till the same hour on Monday morning.

A general belief prevailing that bag-net fishing for salmon was practised along our shores by parties not legally entitled to exercise that privilege, the advisers of the crown have recently interfered by bringing an action against a Kincardineshire proprietor for fishing along shore *ex adverso* of his own lands. These were the lands and barony of Portlethen, belonging to Mr Ernest Gammell, and possessed by him under a charter from the crown, in which they are described as "All and whole, &c., with the seaport, haven, and harbour of Portlethen, and whole tolls, duties, customs, and anchorages pertaining and belonging thereto, with the white fishings in the sea adjacent to the said lands, and whole privileges and pertinents thereof, all lying within the parish of Banchory and sheriffdom of Kincardine, now erected into a free barony, called the barony of Portlethen," &c. The property is situate to the southward of Aberdeen, and is bordered by the open sea. The action was brought at the instance of the Lord Advocate, on behalf of the commissioners of the woods and forests, against the proprietor and the lessees of his salmon fishery, and on the expressed ground that all salmon fishings around the coasts of Scotland, and in the navigable estuaries, bays, and rivers thereof, so far as the same have not been granted to any subject by charter or otherwise, belong to the sovereign *jure coronæ*, and form part of the hereditary revenues of the crown in Scotland; and that as the charters of the defendant and his predecessors contain no such grant of salmon fishings, he has no right, &c., and never attempted to exercise that right till within the last few years. The prosecutors for the crown had offered to grant a lease of these salmon fishings at a moderate rent, which the defender had declined. The defences were as follows:—1. Mr Gammell being proprietor of lands erected into a barony, the right of salmon-fishing in the adjoining water is attached thereto. 2. The right of salmon-fishing in the sea does not belong to the crown as part of its hereditary revenue. 3. The right of fishing within the British seas is a privilege belonging to, and may be exercised by, all British subjects, and cannot be constrained, or defeated, or interfered with by the crown. 4. According to constitutional law, the right to public fishings vested in the crown is a right of protection for the benefit of the subject, but is not a right of property. 5. The right of salmon fishings in the sea is not *inter regalia*, and therefore the crown has no right to grant it, or any other right which will apply to the fishes of the sea, or interfere with the rights and privileges of the public. 6. The defenders being entitled to take fishes in the sea, and the crown having no right to interfere with the exercise of their constitutional privileges, they are at liberty, and have the legal power of using and erecting such apparatus as they may consider best suited for the purpose of taking and catching fish in the sea.[1]

The question was argued before the court, as regarding a right at common law (the alleged right by charter, which is the first defence, being waived for the time), and the defences were repelled by a majority of the judges, that is, a verdict was given for the crown, by sustaining the first conclusion of the summons—that the salmon-fishings around the sea-coast of Scotland belong exclusively to the sovereign, and form part of the hereditary revenues of the crown in Scotland, so far as not expressly granted to any vassal.[2]

In England, as we understand, the general law is, that

[1] It appears to us that the above defences, all except the first, proceed upon an assumed *public* right, irrespective of the private possession of the adjoining land, and so would throw the right open to all British subjects. We are therefore anxious to know what Mr Gammell would do if half a dozen traders from Aberdeen, and a like number from Stonehaven (the place in question lies exactly half way between the two), were to take a fancy for Portlethen salmon, and erect a few bag-nets on each side of the same. Would the proprietor, acting upon his own principles of law, insist that they should not be "constrained, or defeated, or interfered with?"

[2] It is understood that some of the judges were dissentient from the actual interlocutor, and the Lord Justice-Clerk Hope, especially, expressed his opposing view, strongly and at considerable length. His lordship was of opinion that the line of argument pursued confounded two distinct things, the *jus regale*, and the hereditary revenues of the crown; and he knew of no authority to consider the former as of the same legal character, or as forming part of the latter. The right to make grants of salmon fisheries in rivers is not equivalent

English law.

no right of fishing can be acquired by an individual upon the sea-coast, or in a navigable river, unless by prescription as ancient as the reign of Henry II., or by act of parliament vesting such right in that individual. So jealously have the rights of the public been protected in England, that there is said to be no instance since the passing of the Great Charter of a grant of free fishery being made by the crown, submitted to by the public, and allowed in a court of justice. No such grants as those so frequent in Ireland have been made in England since the days of John, and there is no English authority for saying that they could be made.

Lord Mansfield states the rule of law to be uniform. In English rivers not navigable, the proprietors of the land have the right of fishing on their respective sites, and it generally extends *ad filum medium aquæ;* but in navigable rivers the proprietors on each side have it not, the fishing is common, it is *prima facie* in the king, and is public. All the authorities concur in declaring that the right of fishing in the sea and public navigable rivers belongs not exclusively to the king, but is common to every one of his subjects. So clear is this, that a plea of prescription of common right of fishing in the sea, as appurtenant to certain lands, has been held to be as idle and absurd as a claim of travelling on the king's highway, or breathing the common air, as appurtenances to a certain estate. Sir Matthew Hale thus expounds the great charter:—Before the statute of Magna Charta, chap. 10, it was frequent for the king to put as well fresh as salt rivers *in defenso* for his recreation, that is, to bar fishing or fowling in a river till the king had taken his pleasure and advantage of the writ *defensione ripariæ,* which anciently was directed to the sheriff to prohibit riviation in every river in his bailiwick." "Riviation," adds Blackstone, "I suppose is a word which implies fishing rights. I never saw it elsewhere." The great charter having been extorted from King John, to prevent a recurrence of illegal encroachments, the construction put upon it in the courts of justice has been, that it is only declaratory of the common law. All the old enactments regarding England are alleged to have been made applicable also to Ireland by the 10th Henry VII. cap. 22. This last is usually called Poyning's act.[1]

Sir Mathew Hale states, that public rivers for the common passage of vessels, whether large or small, are "highways by water," and as much under the control of the king as "the common high-ways on the land;" "and as the high-ways by land are called *altæ viæ regiæ,* so these public rivers for passage are called *fluvii regales* and *haut streams le roi,* not in reference to the propriety [property] of the river, but to the public use; all things of public safety and convenience being in a special manner under the king's care, supervision, and protection; and therefore the report of Sir John Davis, of the piscary of the Banne, mistakes the reason of those books that call these *streams le roi,* as if they were called so in respect of propriety, for they were called so because they are of public use, and under the special care and protection of the king, whether the soil be his or not." Schults says, "A high-way is called in the old books *le haut chemin le roi;* yet it was ad-

to the proposition that all the salmon in the rivers of Scotland, if not granted out, form part of the hereditary revenues of the crown. The right is derived from this, that a salmon-fishery being a *jus regale,* that is, one of the higher rights of property, supposed by fiction to be peculiar to the monarch personally for his own sport or pleasure, and so reserved from ordinary grants, must be given specially with a view to its being devolved upon a subject. But assuredly no one has ever said that the salmon of all the rivers in Scotland formed part of the hereditary revenues, that is, of the proper patrimony of the crown, for if so, then no grant whatever would be competent, being struck at as an alienation contrary to the statutes. His lordship apprehended that there was no authority whatever for holding salmon-fishings to be any part of the hereditary revenues of the crown, or for regarding a *jus regale* as a portion of those revenues. After a careful review of the authorities regarding *jura regalia,* he had satisfied himself that none of them includes, or was intended to include, salmon-fishings in the sea proper, and that all the writers are treating of those mouths of rivers so often called sea or salt water, in reference to the flow of the tide, and it may be in one or two cases land-locked bays, which seem to be within the proper line of the land coast, and included as it were within that line. The argument founded on the fact that grants had actually been made by the crown of salmon-fishings which were said to be in the sea, was, in his lordship's opinion, inconclusive in point of principle, and weak even as a matter of practice, most of these grants being really in firths, estuaries, or the mouths of rivers, or at a turn where the coast begins to trend off, and where it is difficult to say where the proper sands of the tidal river cease. This he believes to be the explanation of the expression used,—of fishings as well in salt as in fresh water, *in aquis dulcibus quam salsis.* That some grants have been made of salmon-fishings in the sea proper is undoubted; but this may be accounted for by the manner in which grants were formerly obtained from the Scotch exchequer, of subjects which ought not to have been so granted, and to which the crown had advanced no claim, a practice stopped by Baron Hume. "It by no means follows that the rights of salmon-fishings enjoyed by the proprietors who have obtained such grants are therefore not maintainable as valid rights of fishing; although I do not think that the right depends on the grant, I think a station on the shore, or in the sea for stake-nets, bag-nets, or other such machinery, is quite capable of appropriation by the proprietor of the lands *ex adverso,* as a fair adjunct to his property, and a natural use for him to make of the coast, so far as he does not interfere with the right of navigation." "I have no doubt that proprietors, without any such grants, will be able successfully to defend this appropriation of the sea-shore or stations in the sea, as a fair adjunct of their right of property. The plea of the crown would equally prevent the proprietor fishing by net and coble—and the summons distinctly goes that length—and catching salmon by long nets swept out by a boat, and then drawn into the shore; a use of the sea-coast which, I am of opinion, the proprietors may make for salmon as well as for white fish, and the denial of which seems to me to be totally repugnant to all notions of constitutional or feudal law which I have ever heard. I may further add, that I am satisfied that the legislation as to stake-nets and fixed engines was limited in the Scotch statutes to estuaries, where the sea ebbs and flows, and was not extended to the sea, because the legislature only intended to regulate fishings which were the proper subjects of exclusive grants, and did not intend to apply such regulations to the general right common to all, to fish salmon as well as other fish in the sea." "I see that a distinction is attempted to be taken between fishings *in alto mare* as something different from the fishings along the sea-coast. That distinction seems to me wholly to fail, and in the authorities "in alto mare" is used as contradistinguished from the sea in estuaries, but directly as applicable to the sea along the open coast of the island."—*Cases decided in the Court of Session,* &c.—(Messrs Tennent, Fraser, and Murray's *Reports*)—vol. xiii., p. 866.

It will thus be seen that some "glorious uncertainty," so far as great difference of opinion is concerned, still pervades this important question. Meanwhile the ruling judgment maintains the general doctrine of the law of Scotland to be that salmon-fishing is a beneficial interest, and remains with the crown, unless it has been conveyed away. That doctrine is not made to depend upon special situation; but upon the object and nature of the operation. It is true that the localities most generally resorted to were rivers, estuaries, or other inlets, because those situations afforded the greatest facilities for catching this particular fish, which is remarkable for its instinctive desire to leave the open sea and ascend the restricted waters. Our earlier salmon-fishers feared the "injurious sea," because the howling winds and rolling waves were too much for their comparatively feeble gear. "But if in process of time," says the judgment just referred to, "it was discovered that even upon the open coast the possession of the shore might be turned to account for the same purpose, it would be difficult to see in principle why the accommodation afforded by the possession of the coast for the purpose of salmon-fishing should be held to have been carried by the crown charter (meaning a charter without a special grant, *cum piscationibus salmonum*) any more than if the lands had lain along a river or estuary," p. 862. It was well observed by Lord Medwyn that the recent statute, 7th and 8th Vict., cap. 95, which declares that a penalty may be inflicted on any person who shall fish for salmon in the sea within one mile of low-water mark, without permission of the proprietor of the salmon-fishery, necessarily recognises the royal right as one pertaining also to a *sea-fishing.*

[1] A compendious statement of the Fishery Laws, as concerns England and Ireland, will be found in the *Dublin Review* for Nov. 1841.

Salmon-fisheries of the Tay.

judged by the whole court, that all profit arising therefrom, and trees growing thereon, belonged to the lord of the place; and again, that every one has an interest in the king's high-way." Hale compares the king's "right of propriety or ownership" in the sea and its branches to that of the lord of a waste or common, and says, that although he "is owner of this great waste, and, as a consequent of his property, hath a primary right of fishing in the sea, and the creeks and arms thereof, yet the common people of England have regularly a right of fishing in the sea, or creeks or arms thereof, as a public common of piscary, and may not, without injury to their right, be restrained of it unless in such places, creeks, or navigable rivers, where either the king or some particular subject hath gained a propriety exclusive of that common liberty." And the latest writer on the subject says, "All the writers on the common law of England agree that the supreme dominion or jurisdiction of his British seas belongs to the sovereign as the head and representative of his people, and that the free and universal right of fishing and navigation in such seas, ports, and arms of the sea and navigable rivers exercisable under his jurisdiction belongs to the subjects in general. The right of fishing in these seas never was vested in the crown exclusively, and of course is not to be considered as a legal franchise. As a public right belonging to the people, it *prima facie* vests in the crown; but such legal investment does not diminish the right of the subject, and is merely reposed in the crown for the sake of regulation and government." [1]

We shall now endeavour to illustrate the past and present condition of the salmon-fisheries of Scotland, by exhibiting the returns of the river Tay, the greatest and probably the most productive we possess. We shall confine ourselves, in the first place, to the two principal fishings of the upper portion of the estuary.

The most remarkable feature in the former of these tables is the great preponderance which its early periods exhibit of salmon over grilse. We cannot easily account for this disparity upon any natural principle, and have sometimes thought it must have arisen from the nets used in earlier times being larger in the mesh than now, and so admitting of many of the least-grown grilse making their way through the cordage. This escape would tell in two respects, as diminishing the amount of captured grilse of that year, and adding to the number of adult salmon during the one which followed; and this effect would continue to be produced each successive season. However, we have failed to ascertain the fact, that any change or restriction in the dimension of the meshes took place in the Tay so recently as the year 1823. It will be observed from the table, that grilse preponderate during two or three prior seasons—those of 1816, 1819, 1820,—and fall off again for a couple of years; but that after that they greatly increase,

[1] *Report of the Select Committee on the Irish Fisheries*, p. 8. (1849.)

[2] The Perth Navigation Bill, above referred to, is an act of parliament passed with a view to the improvement of the river Tay, so as to admit of easier access from the sea to the "Fair City."

Salmon-fisheries of the Tay.

and keep the lead apparently to the close, with the exception of the seasons of 1839 and 1844.[1]

Although the young of all animals are naturally more numerous than their parents, it is not necessarily so as respects the proportion between grilse and salmon. Young salmon, including their various adolescent stages, are doubtless more abundant than old ones; but as concerns simply *grilse*, it must be borne in mind that these are all the produce of one season, and represent only a single summer of the salmon life, whereas salmon, properly so called, are the congregated or abiding produce of several years. A grilse, whether he lives or dies, can exist, as such, for only a portion of a single season. If he is captured, and sent to market, his days are ended; if he escapes till the ensuing summer, he is converted, by a law of his nature, and whether he will or no, into a salmon. So in either case he must cease to be a grilse. The later of the Tweed returns show that of the whole of the salmon kind captured, including young and old, *four-fifths* are killed on their first ascent from the sea, and consequently before they have become parents, or added to their kind. The severity of fishing now practised decreases the average duration of salmon life. The result of this is, that the fish are not only fewer in number, but smaller in size. The reason that so many forty-pound salmon were found by our anglers in Norway is, that they were old fish in a new field. Far fewer of that size now occur there, because the veterans have been killed out, and the increase of sportsmen has become so great and continuous, that the fish have no sufficient time to grow. The same causes, multiplied a thousand-fold, affect our fish at home. The small proportion that escape from year to year must be a wonder to themselves. To pass from the sea to the far shallows where the spawning-places lie, as many dangers must be successfully surmounted as those which beset our troops between Cabul and Jellalabad. We believe that only a single man ever gained the fortress. Had the conditions of his life required that he must, under a constant continuance of the same perils, have gone back to Cabul, and then rejourneyed to Jellalabad, and so on every season in succession, we could scarcely marvel at his not becoming an old man. A very large salmon must be rather an elderly one, but as no salmon now dies a natural death, and almost all are cut off in the very blossom of their days, it is easy to see how their dimensions have decreased. It is many years since Mr Hogarth (at one period the greatest lessee of salmon-fisheries in Britain) gave his opinion that over-fishing had diminished their size as well as number. "We now seldom see a salmon above two years old." The weight of fish, from the undue prevalence of the imaginative faculty among the sons of men, is frequently exaggerated, especially by the votaries of the rod and line. This inaccuracy seems sometimes to obtain even among the working people of the commercial fisheries. When the celebrated "Rob Kerse of the Trows" (on the Tweed, at Makerstoun) was asked, somewhat upbraidingly, how it happened on a certain occasion that those above him were catching larger fish than himself, he replied, "It's no that the're gettin' ony bigger fish than us up yonder, only the folk themsel's are far bigger leears."

We have no note of the produce of the Tay since the season of 1844, but the following *Rentals* will show the money value of these fisheries for the last 30 years.

The preceding table shows no great variation in the total value of these fisheries during the last thirty years; the produce of 1825 being L.8509, and of 1855 L.8417, with a decline in 1852 to L.6098. But individual properties will be seen to exhibit a wide range in both directions. Thus the fishings of Lord Gray and Sir Thomas Moncrieffe have fallen off, while those of Lord Wemyss, Mr Hay of Mugdrum, and Mr Allan of Errol, have largely increased.

Our next table presents a complete exposition of the captures in the Tay, and its tributary the Earn, for a period of fifteen years.

[1] We have made a calculation from the foregoing tables, that during the three given periods of ten years prior to 1824, there was a total take,—of salmon 352,955, of grilse only 158,611; while during the two periods of ten years between 1825 and 1845 the take was, of salmon 152,950, of grilse 261,535, the proportions being thus reversed.

Table of the Salmon and Grilse caught in the Rivers Tay and Earn, commencing with the season of 1830, *and ending with that of* 1844.

Salmon-fisheries of the Tweed.

It will be seen from the preceding table that the captures frequently vary considerably from year to year, but that on the whole there has been no diminution. In fact, the total of the last three years is greater by nearly 5000 fish than that of the first three. The best year was 1842, the next best 1835. The worst year for grilse was 1839, the worst for salmon 1840.

We shall now exhibit the produce of the Tweed (one of the greatest of the salmon rivers of our country) for the preceding forty-four years. It includes only the commercial fisheries, which are those of its lower districts, and excludes all captures by the rod and the nefarious leister.

Calculated Produce of the river Tweed as transmitted from Berwick.

Average for five Years.	Salmon.	Grilse.	Trout.
1811 to 1815	40,297	68,057	31,235
1816 to 1820	37,938	87,089	48,078

1854	15,299	16,739	32,645
Average for four years	9,774	26,393	35,021

It will be seen from the preceding columns that the Tweed, although with periods of resuscitation, is suffering from symptoms of a deep decline. The greatest year in our record for salmon is that of 1814; the most remarkable for grilse that of 1816. More recently, 1842 was a very productive season for grilse, and that of 1844 was a good one for salmon. These and the adjoining years being favourable, the quinquennial average, as taken in 1845, mounted up. But since 1846 there has been a sudden and large decline, especially of salmon (1848 was great in grilse); although in 1854 salmon rose in number, while grilse fell. It will be seen that the supply of sea-trout is also going down.

Salmon-fisheries of the Tweed.

	Salmon.	Grilse.	Trout.
The totals of our first five years are	201,484	340,285	156,176
The totals of our last five years are	48,617	139,435	189,786
	Decrease, 151,867	Decrease, 210,850	Increase, 33,610

We entertained some hope, from the apparent improvement, at least of salmon, in 1854, that the current season might have turned out a good one. We regret to learn, however, that this is not the case.[1]

In regard to the *rental* of the Tweed, it may be observed that it does not vary in the same way as the produce, as much depends upon the length of existing leases, the prices at which the fish happen to sell for, and a good deal upon the profit and loss account of the tenants, who in some seasons may have a considerable gain, and in others a heavy reverse. For the present year of 1855, it is believed that (unless a very favourable change takes place before the close) not one shilling will be gained by any fishing in the Tweed, and the tenants will consequently have to bear the loss; while the rental, as assessed for taxes, will probably appear not much less than that of the preceding year. At the same time the rent must always in some degree be regulated by the state of the fishing, and the following is the amount at which the Tweed tax has been assessed during the last nine years for all the salmon-fishings in the lower district of the river, which extends from Eden-mouth to the sea:—

For the Year		For the Year	
1846	L.5358 2 0	1851	L.5098 0 10
1847	5435 19 6	1852	4682 10 6
1848	5054 10 7	1853	4561 11 6
1849	5214 1 0	1854	4302 1 6[2]
1850	5051 12 6		

We have taken some pains to ascertain the average value of salmon, which, however, we have found it by no means easy to do, in as far as both the weight of the fish and the prices vary much in different seasons; and, therefore, to arrive at anything like an exact idea of the money value, the weights and prices for each season would require to be taken separately. Mr Paulin informs us that, taking a general view, the Tweed salmon will average from 11 to 12 pounds, the grilse about 6 or 6½ pounds, and the sea-trout from 4 to 5 pounds. Among the latter there is often a pretty large supply of whitlings, which are the younger fish, and which reach about 2 or 2½ pounds each. In the earlier part of the season the Tweed salmon do not average above 8 pounds, but before the end of the season they will weigh above 14 pounds. The following is a note of the

[1] In a communication with which we have been favoured by Mr Paulin of Berwick-upon-Tweed, from whom we received the above statement, he remarks as follows:—"You will observe that the tendency is still downwards, especially with grilse; and I regret to say, that, so far as this season has gone, salmon are not more than one-third of what they were last year—grilse are considerably short of what they were last year, although it was the worst upon record—and trouts are not much above one-half; so that this season has all the appearance of turning out to be the very worst ever known. This is something very unaccountable; for from the extended protection that has been afforded to the Tweed for these four or five years past, and the great expense incurred in keeping up a large police force, it might have been expected that the numbers of salmon, grilse, and trout would have all increased, which is quite the reverse, and almost makes one think that there must be some natural law in operation affecting the breed of salmon other than is generally supposed."—*7th August* 1855.

[2] Mr Paulin adds:—"You will see from the above that the rental of the Tweed has fallen off considerably of late years, and I have no doubt but it will continue to go lower yet, as I have every reason to believe that even the above sums have not been realised as rent from the balance of the produce less the working expenses, for several years past."

Salmon-fisheries of the Tweed.

average value (wholesale prices, we presume) at Berwick for three years:—

	Salmon.			Grilse.			Trout.		
In 1847......	L.0	7	10	L.0	2	2½	L.0	1	2
1848......	0	8	10¾	0	2	1¾	0	1	1½
1849......	0	8	3¾	0	10	7⅞	0	1	0⅝
Average of three years	L.0	8	4⅛	L.0	2	1	L.0	1	1⅜

We are unable to give the exact rental of all the fisheries on the Tweed, but as concerns the lower portions, that is, from the mouth to about 20 miles upwards, we may state the following facts. In 1814, the rent was L.20,000; in 1823, L.10,000; and for seven years preceding that, the average was L.12,000. In 1831 the assessment was upon L.4691; in 1838 it had fallen as low as L.3759, after which it gradually rose again till the recent fall in 1852. As a trading speculation, salmon-fishing may be regarded as precarious, and seldom in the long-run successful. The hope of a successful year, from natural causes, is indulged in, and sometimes gratified, but the profession is an adventurous one, and subject to great mischances. It is understood that frequent losses are incurred by the lessees of fisheries both in Tweed and Tay. But let us hope that the expenses are often more than paid by a successful catch and good markets during the earlier portions of the season, and then, as fish require no feeding, and come uncalled for from the "vasty deep," whatever afterwards enters the net may realize Franklin's phrase, "a bit of silver pulled out of the water." A beautiful and sumptuous bit it often seems to be, although to the angler's eye of brief presentment—"a moment white, then gone for ever."

We may state that there are no fixed nets of any kind allowed within five miles of either side of Tweed-mouth. They are prohibited by an act passed in 1830. But that salmon course, or *run*, as it is termed, along the sea-shore, instead of entering rivers directly from the open sea, is shown both in a general way by the success of bag-nets along our eastern coasts, often in places remote from rivers, but more specially by certain stations near the above five-mile boundary. The number of salmon and grilse captured at a station with two small clusters of nets, occupying only a few yards of beach, and near no flow of fresh water, or indentation of the coast, averaged during the last four or five years preceding 1851, nearly one-half of the whole number taken in the Tweed.

In considering the deficiencies of our salmon rivers, we must bear in mind this increased supply of sea-salmon from our outer shores, and the general fact that no animal killed in one place can be captured in another. The decline during recent years of the salmon-fisheries in so many of our estuaries and the mouths of rivers, may, we doubt not, be attributed to various causes, of which, however, the great increase of stake and bag nets, is the chief. The greater cheapness of salmon in earlier times, so often quoted in proof of its former abundance, must be considered in connection with a much smaller population, a deficiency in the means of transport, and entire ignorance of any plan of preservation by ice. We have been told that the practice of sending Scotch salmon to the London markets packed in ice was introduced by the late George Dempster, Esq. of Dunichen. This, of course, raised the price of fish, and gave a great stimulus to an increased capture. Too many can scarcely now be be taken at a time, seeing that a well-known method is at hand for their at least temporary preservation. In former times all redundant salmon were salted, and this indeed became so regular a trade, that 1000 barrels have been annually preserved and exported from certain stations, the entire produce of which would not now equal one-half of that amount.[1] The salting vats were soon filled, and the fishing ended so early, that grilse, which arrived later, were deemed of little consequence. Of course the upper portions of such rivers as had a good run of water were well supplied with both early and breeding fish, and thus anglers, and all others, whether legal or illegitimate, had ample sport, without interfering with futurity.

Supposed causes of deterioration.

The increase of land-drainage, especially of the open sheep drains of the pastoral districts, is supposed to have proved injurious, by bringing the surface water more rapidly, and in greater volume, into the river, and hastening its descent into the sea. Salmon prefer travelling upwards when the river water is neither muddy and uproarious on the one hand, nor too low and limpid on the other. They prefer it full but clear, that is, by no means clayey. But these required natural conditions are now less easily obtained than formerly, in consequence of man's artificial labours in the improvement of the land. These sudden floods also alter the character and structure of the spawning beds by shifting the gravel, or destroy them altogether after the parent fish have performed their duties to posterity. Many of the more lowland streams are deteriorated in their nature by the increase of human settlements along their banks, and the consequent increase of various manufacturing works, the operations of which produce refuse, abhorrent to the tastes of salmon. Suppose one of these fish about to leave the translucent basin of the Firth of Clyde, and desirous to enter what he considers as a tranquil change into pure sweet water. He first shows himself

[1] It appears from the accounts of stores of provisions for the religious houses given in Dugdale's *Monasticon*, that salted fish, especially salmon, were in large request as winter food. It may be inferred that a great mass of private persons were dependent on a like supply. Even armies could not be marched without their cured fish. We have in Rymer's *Fœdera* an order by Edward the Second to provide 3000 dried salmon for the sustenance of his men; and Monstrelet, when mentioning the defeat of the English, and the capture of their army, adds, "Que grande partie du charoy des dits Anglois etoient chargés de harenc, et à cette cause la battaile fut appellé *la battaile des harencs*." All wild animals diminish in amount as the surrounding tribes of the human race increase in number and civilization. We all know how bountiful is the supply of salmon, or fish of the salmon kind, in the dreary northern regions. So abundant are they at the mouths of certain rivers of Boothia Felix that 3378 were obtained at a single haul. They varied in weight from 2 to 14 pounds, and exceeded in the aggregate 6 tons. This was *Salmo Rossii* of Richardson. Sir George Simpson found salmon so plentiful in the Columbia river, that as many as 1000 per day, some of them weighing above 40 pounds, have been captured in a basket. In a little stream in New Archangel (Russian America), within a mile of the fort, so numerous are salmon, that when ascending the stream they have been literally known to embarass the movements of a canoe. About 100,000 are salted annually for the use of the fort.

Mr Erman tells us (*Travels in Siberia*) that the Russian traders annually fit out great fishing expeditions to the Obi, and settle themselves in the neighbourhood of the most productive sand-banks, which they purchase or hire from the Ostyak inhabitants. The nets used are 800 feet in length. The salmon are salted and packed in tubs, which contain from 800 to 2500 fish each. Some of these Russian companies are said to have recently realized a profit of 150,000 rubles (about L.25,000) in a single summer. "But," adds Mr Erman, "it is at the same time equally certain that the fisheries of the Ostyaks round about were thereby seriously damaged." The Russian official agents, to whom the superintendence of the country is confided, have always been perplexed by the difficulty of reconciling the conflicting interests of the case. M. Kamiloff has proposed a felicitously characteristic expedient to his government, that it should take into its own entire and immediate possession all these valuable fisheries on the Obi, and lease them only to Russians, "for then," he observes, "the harmless and amiable Ostyaks, to whom the sand-banks belong by inheritance, would at once and for ever be relieved from the anxiety of retaining possession of them, and nothing more would be heard of their troublesome complaints of local injuries done to them. The fish-eating inhabitants might then learn to support themselves on the nuts of the Siberian pine (fir tops!), or by catching birds and quadrupeds; so engaged they would not be troubled with competitors, and might enjoy tranquillity of mind!!"

Supposed causes of deterioration.

near Dumbarton like a wedge of lustrous silver, with deep cerulean back, and breast like that of leper, white as snow. He passes upwards, and finds himself in the course of the first night at the Broomielaw, or other now not very rural portion of the river, in the midst of many ships, in the immediate vicinity of 11,965 inhabited houses, and surrounded by a population of 329,097 men, women, and children—his own actual object being to seek some solitary stainless pool, reflecting a lichen-coloured rock or emerald bank, and dappled with many a golden light playing as with living lustre over the beautiful mosaic of its pebbly floor. We cannot wonder that after losing sight of his fair partner in that turbid stream, he should turn tail with disgust, and revisit the mouth of the Molendinar burn no more for ever.

The destruction of fish about to spawn during close time is another alleged cause of the decrease of salmon. Of course a fish killed before it spawns will never voluntarily spawn afterwards, but we doubt not that great destruction of this sort took place likewise in bygone days, and that it is not a new evil under the sun, although the more it is now prevented the better for the future fry. It has been argued that a considerable extension of the period of angling after the commercial close would be beneficial, by enabling the legitimate sportsman to check or overawe the illegitimate poacher. "When we look at the circumstances and the localities in which salmon are bred, and those in which they are killed, the wonder seems to be, not that the supply of this noble fish should be so rapidly diminishing and deteriorating, as that even its immense natural powers of reproduction should have hitherto been able to prevent its absolute extinction. The seed is sown above, and the harvest is reaped below. Those who sow do not reap, and those who reap do not sow,—what, then, more natural than that both processes should be ill performed? There is too little sowing and too much reaping. Those in whose waters the seed is sown say, 'The fish are never allowed to reach us till the law prohibits us from killing them; why should we incur trouble and expense, and offence, for the benefit of the very people who do their utmost to intercept what nature sends us?—let the poachers work their will.' Those who reap say, 'The people above will take no care of these fish; let us by all means capture all we can, careless of the future,—it will last our time,' that being seldom so much as a five-years' lease. And so, between these two operations—a careless and wasteful seedtime, and a rigorous reaping and gleaning—the crops are becoming poorer and poorer, and the harvest-grounds hastening to absolute sterility."[1] There is no doubt that if some accommodating arrangement were entered into, by which more favour should be shown to the upper heritors, resident proprietors, and the higher class of farmers in those uplands, would do much more among their people to check all illegal and nocturnal malpractices in the way of burning and leistering, than however large a squad of hired bailiffs have it in their power to do. The present mode of prevention is not only precarious but expensive—the proprietors of some fisheries paying about 20 per cent. of their rental for that object alone. We hope it may be felt as a check upon the over-fishing with nets before referred to, that it is now beginning to tell along the sea-shore, as well as in the estuaries, at the mouths of rivers, and up the streams and tributaries. It may again be found, as it was once of old, to be but a short-sighted policy to kill the goose that laid the golden eggs.

Supposed causes of deterioration.

But it is evident that when the seaward salmon-fisheries were unknown or neglected, those in the higher stations must have been necessarily in a more flourishing condition. The fisheries on the Tay above Perth bridge produced 11,500 fish in the year 1792, 10,400 in 1795, and never less than 5000 in any one year up to that of 1800. Their *take* in 1850 was reduced to about 1500, and may possibly be decreasing from year to year. This is in no way owing to fewer fish being bred above than formerly, but to far more being captured below. The lower fisheries of the river and tideway have increased in number and activity, and must be worked hard to keep up a remunerating produce, while the owners make a corresponding complaint that the sea-shore fisheries intercept so large a portion of what was in use to ascend their way. In salmon-fisheries, as possibly in several other things, the terms *productive* and *destructive* are relative, and even convertible. A successful stake-net fishery is regarded by its proprietor as very productive, while it is viewed as destructive, exactly in the same proportion, by the owners of more inland stations. There are now as many fish bred as ever, but that they are killed at an earlier age is evident from our tabular views, in which it will be seen how greatly the slaughter of grilse now exceeds that of salmon. But so long as the shore fisheries are worked only by those who have the legal right to do so, the other proprietors can scarcely complain that a new field has been opened by others, which may reduce or equalize their own previously exclusive gains. Of course all that the pensive public desires is a fair field and no favour, in the hope that a larger supply, at a lower price, may accrue to itself.

Mr James Bell, a lessee in former days of salmon in the Tay and Tweed to the amount of L.9200 a-year, stated in evidence before the Select Committee of the House of Commons (1824), that salmon taken in the stake-nets were often inferior to those secured by net and coble, because, unless removed before low tide, the water receded, and left the fish "floundering about, heated, and dying." It is no doubt quite possible to convert, in the lapse of no long time, a good stake-net salmon into a bad one, but the folly of the owner would be more surprising than the state of the fish. Mr J. Crawford, who had been long engaged in the Waterford salmon-trade, gave his opinion to the Select Committee of 1849, that as good a sale could not be made of salmon caught by the fishermen with cots (small boats) and nets as of what were taken by the weir, as, by plunging about in the nets, they are apt to knock their scales off, and injure their aspect and condition. He, moreover, mentioned, in regard to the difference of value between a salmon caught in the sea or in fresh water, that the London salesmen give fourpence a-pound more for a tide-water fish, caught near the mouth of a river; that fish going up, and remaining above three weeks out of the tide-water, into fresh water, become "gray" and of a gluey nature, and that salesmen mark in their account the number of gray fish at 4d. per lb. less than what they pay for the tide-water take. However much people may vie with each other, and even vary their views to suit a change in their own position, we consider no fact in the posthumous history of a salmon more firmly established than this, that the nearer the sea the better the fish. "A salt-water salmon," says Mr Brabazon, "is far superior to one that has been even a short time in river water, the flesh is a better colour, with a large flake of curd between each flake of fish, which is both firm and rich."[2]

---

[1] *Edinburgh Review*, vol. xciii., p. 358.

[2] We have sometimes fancied that even a few hours in river water made a difference in the flavour of salmon. Among other fisheries of his grace the Duke of Sutherland, there is one at Loch Inver, a small sea bay upon the north-west coast, into which the river Inver is discharged at once without any intervening estuary. The salmon are caught with a scringe-net near the mouth, but still in salt water, and about a mile upwards fish of the same tide are captured in a cruive. Both kinds may be tasted at the same meal, and our impression was that the difference was at least perceptible in the slightly fresh-water flavour (so manifest in trouts) of such as were taken from the cruive. Yet an entirely different opinion seems to be entertained by others of greater experience than ourselves. The late Mr

Supposed causes of deterioration.

As the public is beneficially served by stake-nets, and their erection is legal in sea-firths and on open coasts, it would be in vain to complain that they injure the upper fisheries. No salmon can be caught and killed twice over, and the opposing interests cannot be easily reconciled. When up an estuary, or near a river's mouth, there is no doubt that the injury is direct and demonstrable. Mr Buist has shown, from the books of the Dundee Shipping Company, by whom the almost entire produce of the Tay was in former times despatched to London, that during the last three years of the stake-net operations in that estuary (1810, 1811, 1812) the average annual export from the river fishings was only 1665 boxes; while the stake-net fishers exported 4000 boxes—making together 5665 boxes yearly. But during the first three years after the stake-nets were removed, the average yearly product of the river fisheries rose to 4552 boxes, while during the next three years, when the recovery of the river was completed, it amounted to 5930 boxes, being for that later period 265 boxes a-year beyond the product of both fisheries while the stake-nets were in operation. Of course the alteration in the individual fishings and their rents was conformable. Lord Gray's portion of the river, which during the stake-net practice produced in two years only 8534 grilse and salmon, yielded in the same period after the removal of the nets 46,332 of these fishes. The rent, which during the former period had fallen to L.1205, immediately rose to L.4000; and that of the whole river fisheries from L.5101 to L.12,005.

In other estuaries, of course, similar causes produce the same effects. Mr John Stevenson stated to the Committee of the House of Commons, that previous to the introduction of stake-nets into the Cromarty Firth his fishing in the Conan produced in one year 7656 salmon, while subsequent to their introduction the same fishing produced during another year only 633. But during that latter year Mr James Taylor had intercepted in his stake-net no less than 6500.

It was stated to the Committee by Mr Alexander Fraser, that the rent of the fisheries in the river Ness was, sixteen years ago (prior to 1828), L.1055, and had then fallen to L.124. We believe that its commercial value is now even less than the latter sum, although the revenue which is derived from angling may have increased there, as in most other rivers.

In relation to the supposed decline of our salmon-fisheries, we may state that the late Sir Humphrey Davy delivered into the hands of the select committee of the House of Commons (which sat some years prior to the passing of the Scotch act of 1828) a paper containing the following observations and recommendations. "There is a general complaint," he observes, "of the diminution of salmon in fisheries. In the Thames it can scarcely be said to exist; and even in the Avon, the Severn, and the Trent, it is becoming comparatively a scarce fish. The great northern fisheries, and the Irish fisheries, are much less productive than formerly." He then states the remedies for this national evil to be as follows: 1. To suffer more fish to spawn, and fish of all ages and sizes; 2. to prevent any fish from being killed in rivers after spawning; and, 3. to prevent the young or fry from being destroyed. He is, moreover, of opinion that as all salmon and salmon-trout return to their native rivers, so stake-net fishings ought to be abolished, as they enable persons having no interest in the river to cut off almost entirely its supply of fish, as salmon do not go far out into the sea, and always return along the coast, scenting out, as it were, their own river; and that a strong net put across an estuary might destroy in one year the whole fishery of a river. He recommends that no close wears should be allowed, but that there should be always a free passage for fish, so that early fish may go up as well as late fish; that no machinery should be permitted in a river by which the spawning fish may be killed; that nets should be limited to a certain size, so as to render it impossible to sweep a river; and that no angling should be allowed for salmon till May, nor after October.

Proposed remedies.

The remedies named above are more obvious than easy, and have been not seldom proposed both before and since. They undoubtedly go to the root of the matter, but their enforcement is the difficulty. It has been often tried, but seldom effected. The suggestion as to stake-nets, considering the nature of now vested rights, could never be carried into effect, and, so far as the public interest in a supply of good salmon is concerned, ought not to be so. Besides there are no fixed nets in estuaries, as they are illegal wherever the estuary character is demonstrable. At all events, there is no such thing any where allowed as a net *across* an estuary, or even *linum fluminis*. A free passage must be left, and the so-called estuaries have had ample justice done them,—1st, as in the Tay case, where the sea is declared to end when we reach the "Drumly Sands;" and, 2d, in that of the Dornoch Firth, where the estuary is made to extend to the wild moaning of the "Gizzen Briggs," opposite to, and below the town of Tain. Close weirs on rivers do little harm (such are the productive powers of fish) if properly constructed, and the legal "slap" of 24 hours every week is observed. If a free passage were so left open as to accommodate the fish in the favourite portion of their run up the river, they would all escape, and the weir-dyke would not defray the expense of its erection. Like sheep leaping in single files "each after each" over a broken fence, so would the salmon vault through that watery way. If, again, the main rush of the river were deceptive, and contained a cruive with *hecks*, and the actually open space were in some out-of-the-way quiet corner, the eager and impetuous fish would never make the discovery, nor find out their mistake till it was too late to mend it. If any of these early summer fish got through, their after capture would no doubt please one or more of the upper proprietors, but they would be of little use, parentally considered, because they must bide their natural time to the close, and when that time comes there will be many far fitter for parental functions than themselves, even should they escape the angler's lure. To limit the dimensions of the net would be of little use in rivers the two sides of which, as so often happens, belonged to different persons, and who, if they did not agree to the usual practice of taking alternate sweeps of the whole, would each incessantly harry his own half. To allow no angling till May would deprive the rod-fisher in the earlier rivers of his best months, when the fish are fresh and the waters full. To debar angling after October, or, in other words, to permit it to the close of that month, would be merely an extension of the present period (except as concerns the Tweed, which has seven days more), although, from the mode of expres-

Mackenzie of Ardross, who cherished peculiar views of many other things besides salmon, writes as follows:—"Salmon are always better for being a few days in their native water. It increases, like crimping, the firmness of the fish; insomuch that while a salmon caught in the morning in the sea is soft enough to be boiled and pickled the same evening, one caught in the fresh water retains its firmness, and would break in the kettle if boiled before next morning. The fish curers or boilers, who are great epicures, always accordingly prefer for their own palates fish that have been some days in fresh water."—*View of the Salmon Fishery of Scotland*, Note to p. 42. In regard to the practice of parboiling salmon immediately after they are captured, in order to preserve the curdy texture, it is a good plan if a couple of days has to elapse before they are eaten. But a friend of good taste in Berwick (who dines on the produce only of the *afternoon* tide), tells us, that if a person *must* partake of a salmon killed in the *morning* of the day it is eaten, it is better to keep it cool till dinner time, and then boil it once for all.

Proposed remedies.

sion used, we know not that extension was the object in view. As leading to stricter preservation in the uplands, we doubt not it would be of use.

In regard to the interest of the upland proprietors, which we have always advocated, and have already referred to, we should like to guard against extreme views. They chance to possess a good supply of fine clear shallow water of a rippling lively character, with abundant beds of clean-washed gravel, such as a fond parental salmon loves to haunt. In these, without much trouble to the proprietor, the parr are hatched, and there they dwell during the days of their innocent childhood, and till such time as they migrate seawards. They measure even at the last only a very few inches in length, and do not weigh more than half as many ounces. In obedience to a mysterious and most irresistible, but wisely ordered, instinct, they suddenly descend to certain marine pastures, where their increase of growth is rapid and remarkable. But they are by this time, it may be, a couple of hundred miles from the margin of those tiny streams where they had passed their childhood. They are now well-grown grilse, or even (supposing their second journey to the sea) large-sized salmon. They have descended by a difficult and devious route, along many intervening lands, into the open sea, have wandered at their own sweet will far into that blue profound; and coasting again shorewards in pursuit of food or frolic, to whom do they belong? Certain shore proprietors, to whom the royal right has been deputed by our gracious Queen, or her august predecessors, erect at great expense, and work with difficulty and sometimes danger, bag-nets, or other ingeniously-constructed modes of capture; and when they thus secure a splendid salmon of 30 pounds weight which calls no man master, can any reasonable being maintain that it belongs to some small proprietor, one of the "children of the mist," who owns the barren banks of a feeble tributary among the distant hills, where it no doubt first saw the dim light of day, but from which it had departed of its own accord, so soon as it felt proudly conscious of having become a smolt? There is surely no unjustifiable interference here. The *parr* may have originally belonged to another person (though not necessarily to the proprietor of its native land, who in all probability had no salmon rights whatever), but it has undergone a remarkable metamorphosis, and passed, it may be said, into another state of existence; and, as a *salmon*, it now belongs to whoever possesses and puts in action the legal right to catch it, whether in salt or fresh water. But undeniably there is a natural and necessary connection, as in the relation of cause and effect, between the breeding places above and a productive fishery below; for while we know that without the sea there would be no salmon, so we also know that without the streams there would be no parr—therefore no salmon. But the sea, as usual, is the mightier and more influential power, and eventually yields upon the river produce an increase of many hundred fold. Thus, all that any upland heritor could reasonably claim as his particular share in any salmon would be a small cut about the length of, but otherwise no larger, than his middle finger. At the same time he is entitled to many of these, as his progeny, though minute, are multitudinous; and the unkindest cut of all is that which debars his almost ever seeing a single fin of them again till they are as black as ink, or as rusty as old iron,—for these are the conditions in which the grown fish revisit the shallow streams of their nativity. But the case is too often argued, as if a parr bore the same relationship, even in its extrinsic conditions, to a salmon, as a lamb does to a sheep,—as if the first owner not only bred, but fed and brought it up, and so was entitled to it in its final and complete condition. It is obvious that it is not so. But as the river heritors alone have the direct power of improvement, by breeding and preservation, in their own exclusive hands, it would be good policy to induce them (by making it worth while) for their own sakes as well as those of others, to exercise that power. There is no doubt that the royal grants of river fisheries were given long before those of the coasts were thought of. They proceeded on the observed and ascertained habits of the fish—their periodically entering into narrow waters, and were express in relation to rivers, estuaries, and other inlets; and mainly for this reason, that salmon-fishing, unlike many other kinds, cannot be accomplished independent of the uses of the land. These fine fish do not take in the sea with hand lines, or long lines, or in any other way requiring an act of volition on their own part. They afterwards, no doubt, exhibit a fantastic fancy for artificial flies; but this, with scarcely an exception, is an appetite acquired or manifested only in fresh or running waters. In earlier times the mechanical portion of the art (with the exception of cruives) was comparatively feeble, if not imperfect; and it is only in modern days, when men have sought out many inventions, that the continuous strength of stake-nets planted upon shoal ground, and the resisting power of bag-nets placed in deeper waters, have been brought to bear up enduringly against the force of winds and waves, and the surging swell of the heaviest tidal currents.

Many regard it as a great loss both to Tweed and Tay, that these noble and productive rivers should be divided into so many distinct fishing stations, all wrought separately, whereby the expenses are much increased. Fixed nets require far fewer men, and catch far more fish. On the other hand, the tear and wear at the fixed stations is greater than for net-and-coble. The comparative advantage of simplification in the mode, and fulness of occupation to the people, forms the problem in political economy before referred to.

"The grand evil in the salmon-fishery," observes Mr Mackenzie of Ardross in 1834, "is the multiplicity of fishings, which begets so many contending interests, and makes each individual pursue a selfish system of destruction incompatible with the improvement on a great scale of the fishery. If anything could justify the violation of private rights for the benefit of the public, the owners of minor fishings should be made to sell their rights for a just equivalent, in order to concentrate the fishery as much as possible. If a whole river belonged to one individual, he might do with it as he liked. In such a river there should be no close time. The owner of it would take care to keep it at all times full of breeding fish. He might make it like a game preserve, in which immense quantities would be reared. He would restrict the fishery entirely to a few stations near its mouth, and fish these constantly while clean fish appeared, supplying the public with new fish as they came on, even at the period the old fish were breeding in the upper parts of the river, without the smallest injury to the fishery; but a single upper heritor, were his fishery not worth L.5 a-year, could put a stop to the whole plan. There are, accordingly, no rivers in the kingdom at present under so complete a system of improvement as those of the Duke of Sutherland in Sutherlandshire, under the able direction of Mr Loch, M.P. But this cannot happen in rivers which belong to different proprietors, and, therefore, a close time seems absolutely necessary for such rivers, that is, such a close time as a majority of the proprietors should consider best suited to each river, it being always understood, as we have already said, that the interest of the owners of the rivers and of the public is necessarily the same, viz., the production of as many fish as possible. On the coasts, if coast fishings are to be allowed, the close time should always commence some weeks earlier, as the fish towards close time do not proceed quickly on, and may take that much time to reach the rivers, so that the fish that would pass the coast fishings during that period would not be killed at the rivers, but would be left for breeding.

Proposed remedies.

"We believe that one of the reasons which influenced Mr Drummond in establishing a general close time for all the rivers was, lest the salmon of one river might be smuggled to market as coming from another. But what did it signify, if the fish were *clean*, from what river they came? And foul fish never can be sent to market as clean fish, for their *appearance* would betray them at once. The deception would be seen at a glance. As well might a man attempt to sell a black horse as being a grey one. In truth, no salesman would now venture to present foul fish at market; and if the fish are salted or kippered, we would defy any man to determine whether they were killed a week before or after close time, or, indeed, to bring *legal* evidence to bear on the subject; since, as we said, salmon are as foul in some rivers in August as they are in other rivers in October. Besides, protection to one river can never be a good reason for injustice to the owners of another; and nothing can be more grossly unjust than to deprive the owners of the rivers Ness and Thurso of a great part of their properties, lest foul fish from the Tay or Tweed should be sent to market as coming from those rivers. If the Tay or Tweed are poached, let the proprietors be at the expense of a greater establishment of river keepers, and not look to the annihilation of other properties to save their own purses."

There is no doubt that the Ness and certain other early rivers are put at a disadvantage by the longer continuance of the close time now than formerly. It was proved in evidence before a select committee of the House of Commons in 1825, that when the mid-winter fishings were open, the amount of salmon killed in the Ness during eight years (from 1811–12 to 1818–19) made a total for the months of

December[1]	2405	May	1127
January	3554	June	170
February	3239	July	253
March	3029	August	2192
April	2147	September	430

It further appears, from the evidence above referred to, that during these years no *grilse* ran up the Ness till after the month of May. The month of

June produced	277	August	4229
July	1358	September	1493

We may here observe, that the fluctuations in the salmon-fisheries seem to result not unfrequently from causes over which we have not only no control, but regarding which we have scarcely any acquired or actual knowledge. Clear dry weather, not unusual during the midsummer months of June and July, never fails to affect disadvantageously all fisheries at any distance upwards from a river's mouth. July and August are the chief months for the upward run of grilse. The longer they abide in the sea the bigger they become, so that a September fish fresh from the salt water is twice the size of a June one. The existence in our rivers towards the end of winter or in early spring of grilse which have spawned, and yet weigh only three or four pounds, is of itself a conclusive proof of the retardation of growth in fresh water. These small fish must have entered the river water soon after midsummer of the preceding season, but had made no progress. Had they remained in the sea till autumn, their dimensions would have been considerably greater; or had they spawned sooner, or descended more speedily to the sea, they might have returned riverwards in spring *as small salmon*, while their less adventurous brethren of the same age were still in the streams as grilse.

The working of net and coble does little or no harm to the fry, and cannot injure the spawning beds, either by displacement or otherwise, because these are always either higher up, or in shallower water, than suits the process. Many of the best breeding places are in the tributaries, and the majority of these have never any salmon in them during summer. The clearness of the water at that time, and its small amount, as effectually debar their ascent as if a cruive dyke were thrown across their mouth. Fish in a large river have been known to wait for six weeks near the still too shallow mouth of a favourite tributary, that they might ascend the latter with a view to spawn, rather than continue their journey up the former, which was not their native home. They ascend in the course of the autumn floods, and descend again when the winter is well advanced, and during early spring. Thus the majority of these upland beds are nothing but nurseries, of little or no value to the proprietors, but of infinite importance to the seaward owners of the salmon-fisheries down below. In the Tay, for example, there is no fishing of any consequence (angling of course excepted) beyond the mouth of the Isla, about eight miles above Perth, although Lord Breadalbane has a few good hawling places in Loch Tay, and fish continue their courses into the wild uplands watered by the Dochart, as far as they can go. We saw, when last in that quarter, a brace of fine salmon, rather gray, but in excellent eating order, and weighing nearly 42 lb. the pair, killed with the fly, a short way below the well-kept hostelrie of Luib. But upon this principle of non-ascent in summer, many upper proprietors of small streams, although entitled to consideration, are in error when they suppose that fine angling would necessarily come their way if there was an earlier close in autumn, or less assiduous fishing down below. There cannot be many well-conditioned fish in the smaller streams, because they do not desire to *run* till the commencement of the autumn floods. If there was no net-and-coble fishing during the first fortnight of September, no doubt some fine fish would make their way well upwards; but even if all obstructions were removed, there would still be no good summer angling for salmon in the higher or smaller streams owing to the deficient supply of water, and its extreme clearness. No modification of the present law would give good angling in the upper countries that would not be too injurious to the commercial fisheries; but a somewhat earlier close would be of advantage to both parties—immediate to the one and eventual to the other.

In favour of an altered close time, that is of an *earlier close*, it ought to be borne in mind that the parent fish which ascend from the sea in autumn are the best and most productive breeders, although themselves of less value as articles of food. Those which ascend later, or in wintry weather, may be also good breeders; but the conditions under which they then exist are less favourable for the deposition and future safety of the spawn.

It has been distinctly ascertained that no salmon grows, or at least increases in weight of flesh (although the bony structure may be enlarged), after it has entered the fresh waters. On the contrary, it rather decreases in weight, as it admittedly deteriorates in condition, and consequently in value, as a marketable commodity. We think it is a fair inference, and believe it to have been confirmed by actual observation, that salmon, whether male or female, entering a river in spring or early summer, and remaining there for months, would, from the deteriorating influence of river water, and the absence of their highly nutritious marine diet, whatever that may be, suffer not only in the fulness of their general condition as to fat and muscle, but also in the development of their sexual attributes. It is indeed an ascertained fact, from repeated observations by various individuals, that many female salmon which have been long in fresh water, have the ovaries not only not increased by the advance of the season, but sometimes diminished almost to extirpation. Thus it is probable that the use of such individuals as breeders is lost for a year at least, if not for ever.

[1] Some of the Irish rivers also yield a good December fishery of clean salmon, or did so before restricted by a change of close time.

Autumnal fish the best breeders.

If, on the other hand, they are still able to propagate their kind after this lengthened sojourn in the "rivers of water," there is a probability that their progeny will be less numerous, and of inferior nature, to such as derive their origin from parents fresher from the sea, and in which the sexual system is capable of more fully performing its functions.

It is satisfactory to consider, in connection with this view of the subject, that the capture of salmon in spring and summer does not in fact interfere with a good and abundant supply of future fish. On the contrary, that it is better that such supply should proceed from the autumnal *run*, and thus two objects are attained,—1st, the markets are furnished for a length of time during spring and summer with fresh-run and finely seasoned fish, the spawning period of which is far distant; and, 2dly, the young brood are produced by parents which have been nourished for a prolonged period in the sea, and although deteriorated as articles of food by the advanced condition of the spawn, that spawn itself is fully developed—the chief consideration in respect to breeding fish.

But although the late-run fish are the best breeders, the sooner that these are encouraged to spawn the better. When the net-and-coble and stake-net fishings are continued working well into September, a large proportion of the finest early-breeding fish are destroyed, and just at the time that their breeding functions might be most successfully performed. About this period the fords or shallows (the chief spawning places) are well filled, although not overfilled, with water. The fish are consequently not tempted to spawn too near the margins, which they are apt to do in floods, and in which case the spawn is likely to be left dry when the waters recede. At this time, too, the rivers are free from ice, which is injurious to the brood, not so much by destroying the spawn, which is of a hardy nature if once properly laid and covered up, as by preventing the process of spawning itself. Or if there is no severe frost during the late or winter spawning, then floods or *spates* occur, and are very hurtful, because, although the parent fish always prefer spawning in lively or rippling water, they cannot of course do so advantageously if the current over the shallows is too strong. This increased current is apt to sweep away what would otherwise be the sinking spawn, or prevent its being properly covered up.

Thus, as either flood or hard frost is disadvantageous to the successful performance of the spawning process, the greater number of fish that are allowed to spawn early the better. For this an additional argument may be assigned. There is every reason to believe that fish which spawn early descend again all the sooner to the sea as kelts, are there invigorated and renewed in strength and condition, and return early to the rivers, so that at least a portion of them will seek to re-ascend as clean fish in spring, when the marketable value of salmon is greatest. A sufficient number of salmon will always remain throughout the summer season in the sea, and ascend towards the spawning beds in autumn; and so great is the productive powers of these fish, that a comparatively small number of breeders, if properly protected, and allowed to spawn successfully during the most fitting period, will suffice to stock the rivers, so that no limitation need be made of the numbers caught during spring and summer.

From the principle here set forth, it will follow that no particular advantage need be expected to follow from preserving the courses of a river from the angler during the earlier or middle portions of the season. For example, we do not see that any great benefit would arise to the Sutherland rivers from the spring and summer jubilee of 1848, because, as no fixed obstructions are offered to the ascent of the fish there after the 25th day of August, a sufficiency of spawning fish would be sure to make their way upwards in good time from the sea, and would prove better spawners than those which had previously ascended the rivers. We would therefore even go the length of saying, that it would be better for the spawning beds not to be subjected to the chance of being occupied except by the autumnal-run fish, and therefore the smaller the number of early (and necessarily deteriorated) salmon which have abode long in the fresh water that are allowed to remain in it during the actual spawning season the better. This is of course an argument in favour of rod-fishing, and the mere fact of its being agreeable and advantageous to the angler is certainly in no way against it, if otherwise true. If all stake-nets were dismantled, all bag and cruive nets removed, and all net-and-coble fishing terminated, by the 20th of August, we have no doubt that a deal of productive spawning would take place in September, and that a corresponding increase of grilse and salmon in our rivers would eventually take place. Rod-fishing might be continued without disadvantage up to the 20th of September. The chief damage to spawning fish is done by the poacher's leister rather than by the angler's rod. The fish, while engaged on the shallows best adapted for spawning will not take the angler's fly, although the leister takes them whether they will or no. There are always, even in autumn, fish less advanced with spawn than others, and which keep for a time in the deeper pools and stronger currents, where the angler chiefly plies his vocation; and the taking out of these fish is much less wantonly injurious than destroying the others, both because they are themselves in better condition, and so of greater use, and because, as winter breeders, they would run the risk of spawning (as already stated) under disadvantageous, possibly unproductive, conditions. Angling being also a favourite recreation, and frequently advantageous to the proprietor as a source of income, it carries its compensation along with it. And another direct advantage, we doubt not, would arise from the fact, that while the authorized and legitimate angler is on the river, the illegal poacher is more likely to keep away from it, and the greater value of the privilege of angling, if continued after all kinds of *netting* have ceased, would induce proprietors and lessees to be more active and zealous in their general guardianship of the streams. As a matter of political expedience also, it may be advisable to allow an extension of time in the angler's favour, as not unlikely to propitiate some legislators, who might otherwise object to any change at all.

We doubt whether a bill proceeding, as was at one time proposed, upon a presumed knowledge of the varying habits of salmon as entering certain rivers sooner or later than others, and so dividing the country into different districts, could be either made practical in its application, or worked with good effect. A lengthened inquiry and investigation of the actual facts, and a detailed and authenticated report upon their ascertainment, would be indispensable; and it might be difficult to reconcile competing interests, or draw distinctions between rivers physically the same though in different districts, or physically different though in the same district. A river flowing out of a valley filled with water (that is a lake) may fall into the sea in the near neighbourhood of another river which in early spring draws its main sources from numerous alpine streams subjected to the icy influence of frost. The lake-born river will be an early one, that of the open valley and hilly district a late one, or at least later than the other, although both co-exist in the same district; so that almost every river might require to be defined and designated in the act, and an appropriate clause inserted in relation to each. This complication would be found inconvenient if not impracticable. At all events a commission of inquiry would be necessary to furnish the groundwork of any admissible enactment proceeding upon the principle of local divisions, or districts. A general act may doubtless entail some little

Close-times. hardship by debarring the natural advantages of a few peculiar rivers, but on the whole the general interests will be best guarded by an act of general application. A restricted act, applicable to a single river, might, in many cases, be difficult to decide upon, even by the proprietors themselves, in so far as the interests of the upper and lower heritors are not only different, but stand directly opposed, or at least are deemed to do so. A proprietor of a stake-net in the sea, or of a net-and-coble fishery in an estuary, might possibly deem himself aggrieved by such an early close as would benefit him whose restricted stream winds its far upland course among the desolate hills, and whose only chance of a well-conditioned fish must almost entirely depend on, or at least be greatly increased by, an early termination of the commercial fishery down below. In the long run, we believe, the advantage would be mutual in the more careful protection of the breeding fish, which would soon ensue, and the consequent increase of the general stock.

The upper proprietors would thankfully accept of what, under the circumstances, they are entitled to—a week or two of rod-fishing—as some compensation for what they have lost in modern times by the increased and more skilful application of the various devices now fallen upon by the lower and seaward proprietors to ensnare the finny tribes. These upper heritors have but a slight chance of ever catching a good fish in their own waters, although the responsibility, and a portion of the expense, of protection during the breeding season, are not seldom thrown upon them. They are thus, as Sir Walter Scott used to express it, reduced to the condition of mere "clockin' hens" for the hatching of other people's eggs.[1] As to actual injury committed by the angler, it ought ever to be borne in mind that the rod is but a precarious engine of death, at no time very deadly. From the frequency of floods in the end of autumn, not a great many days during the last three weeks of the season would with certainty afford successful angling; and a strong salmon not seldom takes his own way both with hook and line, although he must succumb to the nocturnal glare of the burning brand and the leisterer's deadly spear.

The art of angling has been for a length of time among the most highly favoured and most assiduously pursued of all our British sports, and has consequently become of great value to proprietors in a pecuniary point of view; so whatever is likely to add to that value becomes of great importance. Many considerate people are of opinion that some modification of the laws relating to salmon would be advantageous, but the subject is jealously regarded by others, and several attempts to obtain a modification of the existing act of parliament (9th Geo. IV., cap. 39) have failed. In rivers which pertain entirely to a single person, or in others where the various proprietors have agreed to act in unison, the use of nets and cruives is voluntarily given up some time before the legally required period, and advantage has been found to result therefrom. It has hence been inferred, that if this wise practice were enforced in all rivers, still greater benefit would arise. What is called the close time, during which it is illegal to kill salmon, or fish of the salmon kind, extends at present, as regards all rivers north of the Tweed, from "between the 14th day of September and the 1st day of February"—that is, as we construe it, no one is permitted to angle for or otherwise kill salmon from the 15th day of September to the 31st day of January, both included. Certain southern rivers of Scotland are regulated by special acts of their own, with a reservation for an additional time in favour of angling. The Tweed, for example, closes as concerns nets or commercial fishery on the 15th day of October, but continues open for rod fishing till the 7th of November. It opens both for net and rod fishing on the 15th of February. The Annan, in accordance with its own special act (4th Vict. cap. 18, May 1841) is closed "*between* the 25th day of September and the 10th day of March" as against net-fishing; the legal period being prolonged in favour of rod-fishing until the 1st day of November inclusive, while the day of opening is the same for both modes. The Nith opens on the 10th of March for rod and net fishing, and closes for both on 25th September.

Nothing is more frequently observable, or better known, than the fact that there is a remarkable difference in the habits of salmon of different rivers as regards their period of entering these rivers.[2] Whatever their ultimate object may be, it is clear that the spawning process, which does not usually take place till towards the commencement of winter, cannot be much in the minds of such fish as seek the fresh waters in early spring. It is a mistake, however, to suppose that there is a corresponding difference in the actual periods of spawning. Some rivers have a greater proportion of well-conditioned fish for a later period than others, but to delay or greatly alter the close time on their account would be very injudicious, notwithstanding the admitted hardship upon the proprietors of certain places where fresh-run fish are found in good order even for some weeks after the present close. A select committee of the House of Commons, appointed to inquire into the expediency of regulation by a varied rule, reported (in 1836) as follows:—"The only object of the close season being to afford protection to the fish when they are breeding, and during their state of exhaustion consequent upon it, your committee are of opinion that the legal close time ought to be so regulated as to coincide as nearly as possible with the period so defined by nature. It has been established in evidence, that in different rivers *the periods at which the salmon ascend the rivers for the purpose of spawning*, and afterwards descend towards the sea, vary considerably, and therefore, upon the principle above laid down, your committee are of opinion that it would be advantageous to the general interests of the salmon-fisheries of Scotland to have the fence-months or close time so regulated according to the respective rivers or districts, instead of having one uniform season as at present." It was upon this principle that the bill introduced by the late Mr Patrick Stewart and Mr James Loch was framed, not, we fear, without some confusion of the running and the spawning periods, which have often little to do with each other. It divided Scotland into twelve districts, the majority of which were made to differ from each other in their times—the Ness, for example, being made to close from the 16th day of July to the 1st day of December, and so on with the others, only three of them remaining as they are now. Fourteen clear days were to be allowed in each district after the close for the

[1] The illustrious sheriff of Selkirk had a kindly bias towards the sports of the people, of which the spearing of salmon is one of the most ancient and exciting. He no doubt often saw, amid his own nocturnal musing, the flickering lights along that turfy shore, starring the far reaches of the river, while he listened to the leisterers' cry, with no "act anent the killin of black fish" in all his thoughts. He has even thrown himself (dramatically) with great gusto into the feelings of those who have sometimes taken the law into their own hands by the destruction of "fixed engines" at a river's mouth. "In truth I heard it, provost; and was glad to hear that the scoundrels had so much pluck as to right themselves against a fashion which would make the upper heritors a sort of clockin' hens to hatch the fish that the folks below were to catch and eat."—*Redgauntlet*.

[2] The subject of the close time is still further complicated by the fact that several rivers yield both early and late fish, because certain of their branches or tributary streams produce some the one and some the other, all having previously to ascend by the same channel from the sea.

District system.

purposes of angling. This bill was either abandoned or thrown out, and a similar fate has attended several others. A previous one had been introduced by the same parties (in 1835), which proceeded on the principle that the proprietors of salmon-fishings in rivers, at a meeting to be called as therein provided, should determine, by a majority of their number and value, the period of close time in each river, &c.; that there should be no fishing for salmon after 1st September, but that twenty-one days should be allowed for the exclusive use of the rod after the commencement of the close time. In 1839 two bills were brought in by Mr Wallace and Mr Hume—one proposing that the fishing season should commence generally over all Scotland upon the 10th of January, and terminate upon the 24th of August—the other legalising twenty-one exceptional days in favour of angling with the rod. Passing over one or more intermediate attempts at legislation, we may briefly notice the bill prepared and introduced by Mr Edward Ellice and Mr Thomas Mackenzie in the spring of 1842. With a view to reconcile or accommodate the interests of all parties, it threw the arrangement and decision of the whole affair into the hands of the commissioners of the Board of Fisheries, thus assimilating the Scotch to the Irish system. It was likewise laid upon the shelf. The latest attempts at salmon legislation was the bill introduced by the Duke of Argyll, and which passed through the House of Lords in 1851. It made the close time commence somewhat earlier than it does now, was more stringent in its enactment in relation to the "Saturday's slap" of stake-nets, &c., and gave the angler a chance of some amusement for a week or two in the upper country by prolonging the period of the rod. It was rejected by the House of Commons. So the regulating act for Scotland is still the 9th of George IV., commonly called Home Drummond's Act, passed in July 1828.[1]

One of the boldest proposals for the simplification of the salmon-fisheries of rivers has been given in recent years.[2] The writer holds that the entire system, whether by fixed or moving nets, proceeds on a false plan, bequeathed from times under different conditions, which performs badly and expensively what might be well accomplished at a small cost. His plan of radical reform is this,—to erect and work in each river, at such place or places as might be found most suitable, some engine which shall, with easy and well regulated alternations, capture every ascending fish, or allow all, or a sufficing number, to pass up at proper times, dividing the produce among the proprietors of the present fisheries, in such proportions as shall be equitably ascertained by evidence and arbitration. We fear, from what we know of human, as well as of salmon, nature, that this scheme is Utopian, and will never come to pass. Another and a prior proposal was made by Mr John Younger of St Boswells, an ingenious writer of the hard-working and self-taught school.[3] Having full knowledge, and a high estimate, of the great angling value of the Tweed, he is of opinion that no other engine but *the rod* should be allowed at all, and that its use should be legalized by act of parliament all the year round. There is no doubt that our rural and village population, having an impression, however erroneous it may be, that their natural rights are somewhat unfairly abridged by the privileged claims of the higher orders, consider close time as the poor man's proper, because now only, period. Being also a time of delegation to the water-bailiffs, these watchmen of the night are more easily evaded, or effrayed, than would be the local lairds or tenants, had the latter any great inducement to interfere. Of all the fresh-water piracies, the practice of leistering is the most deadly and destructive, as well as daring, and is habitually effected in spite of whatever police force may be arrayed against it. As the use of the leister is, for the most part, a nocturnal practice, and lights (in themselves illegal) are necessary both to detect the fish and to astound them, the poachers can scarcely hope to conceal their nefarious proceedings, and so assemble in full force. With "visage discomposed," that is, with blackened faces, and otherwise arrayed in wild attire, they descend upon a spawning place, where, it may be, fifty pair of large and heavy fish are gathered together, and with blazing lights and long-shanked leisters they com-

[1] Although exceptional cases may occur in several rivers, it is certain that the great mass of salmon are in bad condition by the month of October, and frequently long before it. They continue, with the same exceptions, in that unsound state for many months thereafter. The present act of parliament is an "Act of Uniformity" for all rivers north of the Tweed, and although it may bear hard upon the Ness and other early streams, it would be difficult to enact local regulations, giving a difference of times to different districts. As the subject, however, is not unlikely to have legislative attention again directed towards it, we think advantage may arise from our here re-printing the boundaries and their respective seasons, as given in the bill constructed on the local principle, and presented to the House of Commons:—

First District. From Duncansbayhead in Caithness, to Tarbetness in the county of Ross, comprising all the rivers, streams, lakes, waters, estuaries, and sea-coast, situate between these two points, from the *twentieth* day of *August* to the *fourteenth* day of *January*, both days inclusive. *Second District.* From Tarbetness aforesaid, to Fort George Point in the county of Nairn, including the Beauly Frith and the rivers connected therewith, except the river Ness, from the *twentieth* day of *August* to the *fifth* day of *January*, both days inclusive; and for the said river Ness, from the *sixteenth* day of *July* to the *first* day of *December*, both days inclusive. *Third District.* From Fort George Point aforesaid, to the Knockhead of Cullen, in the county of Banff, from the *first* day of *September* to the *seventeenth* day of *January*, both days inclusive. *Fourth District.* From the Knockhead of Cullen aforesaid, to Trouphead in the county of Banff, from the *fourteenth* day of *September* to the *thirty-first* day of *January*, both days inclusive. *Fifth District.* From Trouphead aforesaid, to Dunottar Castle in the county of Kincardine, from the *first* day of *September* to the *seventeenth* day of *January*, both days inclusive. *Sixth District.* From Dunottar Castle aforesaid, to the Redhead in the county of Forfar, from the *fourteenth* day of *September* to the *last* day of *January*, both days inclusive. *Seventh District.* From the Redhead aforesaid to Fife Ness, from the *twenty-seventh* day of *August* to the *twelfth* day of *January*, both days inclusive. *Eighth District.* From Fife Ness aforesaid, to Berwick Bounds, from the *twenty-seventh* day of *August* to the *twelfth* day of *January*, both days inclusive. *Ninth District.* From the confines of the Solway Frith to the northern boundary of the county of Ayr, from the *fourteenth* day of *September* to the *thirty-first* day of *January*, both days inclusive. *Tenth District.* From the northern boundary of the county of Ayr, to Ardnamurchan Point in the county of Argyle, including all Western and other islands situated within the parallels of the said two points, from the *fourteenth* day of *September* to the *thirty-first* day of *January*, both days inclusive. *Eleventh District.* From Ardnamurchan Head aforesaid, to the Point of the Coygach in the county of Ross, with all the Western Islands situated within the parallels of these two points, from the *first* day of *September* to the *seventeenth* day of *January*, both days inclusive. *Twelfth District.* From the Point of Coygach aforesaid, to Duncansbayhead first hereinbefore mentioned, from the *twentieth* day of *July* to the *sixth* day of *December*, both days inclusive; and for "the Lewis," from the *first* day of *August* to the *seventeenth* day of *December*, both days inclusive; and for "Harris," from the *tenth* day of *September* to *twenty-sixth* day of *January*, both days inclusive.

When about to apply to Mr Loch for some information regarding the natural data on which the preceding divisions were established, we heard with deep regret of the death of that estimable person.

[2] *Edinburgh Review*, vol. xciii., p. 367.

[3] Mr Younger is by trade a shoemaker, and dresser of artificial flies, in the village of St Boswells. He has written an excellent little book *On River Angling for Trout and Salmon* (Edin. 1840), and is also the author of an essay *On the observance of the Sabbath*, which gained for him an English prize, and led to his showing himself on the platform of Exeter Hall, from which we doubt not he gladly returned to the gentler murmurs of the Tweed.

Mr Younger's proposal.

mence, and speedily complete, their remorseless slaughter. Meanwhile a dozen paid bailiffs may be innocuously shivering on some neighbouring height, but no more able to interfere with what is going on than Tam O'Shanter in the midst of the witches' joyous dances would have dared to seize upon the black piper. This practice is still a prevailing one in the higher portions of the Tweed, and is prosecuted with the greater facility and success, in consequence of the tenants, or resident proprietors, if such there be, finding it more difficult to sally forth at dead of night to prevent such improvident destruction, than to tarry at home and divide the spoil. Such a dialogue as the following may be not unfrequently heard between a farmer's servant and his employer during close time. "Maister, twa or three o' us are thinking o' lighting a bit bleeze at the *reds* (spawning beds) the nicht, up at the shaw-brae fords, whar we saw them tumlin up this afternoon, like brewers' swine drunk we maut-draff." "Weel, Davie, I daresay, for my pairt at least, ye may just tak what ye can get when ye hae them here, as I'm sure I havena seen three good fish in our water thro' a' the simmer. They kep them a' about Berwick or Norham now, wi' their lang nets, except just a while at the tail o' the saison, when the floodings get ower heavy for their net warks."[1]

Before the passing of the present act of parliament the Tweed opened on the 10th of January, which was much too early for so late a river, and interfered with the breeding fish. As it now stands, the time (15th February) is fully too soon, as it gives occasion to the catching of so many newly-spawned, or otherwise ill-conditioned fish.[2] It also involves this further inconsistency, that leistering, and all other unkindly and injurious practices, which are illegal on the evening of the 14th of February, become legal on the morning of the ensuing day, when they cannot be put in practice without an equally unnecessary waste of life, in the destruction of fish almost utterly useless for all domestic purposes.

Now Mr Younger's proposal is, that as the proprietors consider the produce of the running waters of as much importance as the productions of the solid land, they might make the former much more valuable as concerns both profit and pleasure, by abolishing all net and leister fishing at whatever time, and instead of expending their money in maintaining a strong, though seldom effective force of bailiffs, they should raise funds to lease all the now commercial fisheries at the river mouth, or upwards, so as to admit of a free and continuous accession of fresh-run fish all the year round. "If the net-fishings are worth being rented by individual tacksmen, they are surely worth more in value (overlooking the sport) to the whole proprietors of seventy miles of the Tweed. Those rents would be, individually, a mere fractional consideration to the rents that might be drawn in letting mile-lengths to gentlemen rod-and-line anglers, who cannot, under present arrangements, be one-hundredth part accommodated. The benefit, too, to the localities where the anglers would be thus attracted by their favourite amusement, would be worthy of consideration. The distribution of salmon in the river generally would depend solely upon casual floods throughout the year. There would always be plenty of fish for the rod; many would live to attain to a great size, and rod-fishing would then be one of the most pre-eminent, desirable, healthful, and exhilarating standard amusements in our country. It would beat Grecian games, as well as English horse-racing and hound-coursing, all to nothing. The bodily exercise then would place the angler on the top of the calculation of the bill of health. The excitement would be one of the most nourishing principles of the mind, without the engrossment of the faculties from higher pursuits. It would be a charming relaxation from sedentary employments and severe studies, besides an honest source of livelihood for a few poor fellows like myself, who, living by the side of the waters, have from observation and practice, acquired a taste and use of hand in practical fly-dressing, and the preparation of other necessary tackle, rods, and lines, to dispose of to our richer amateurs of high fancy for the gentle craft."[3] We believe that the angling rent of a river, with such a lengthened and continuous, yet finely varied flow, as that of Tweed, might really be made to equal, if not exceed, the present commercial result, which we have shown has not much exceeded L.5000 per annum for many years, and is now far below it. But the plan might be modified so as to admit of an occasional, yet advantageous, working of one or two seaward stations for the markets, with ever and anon, especially in showery weather, a prolonged period of free ingress to a few thousand "bits of silver," with permission to make their way upwards and along that lengthened course, to be assayed in fair proportions, here and there. An objection, however, to the practical fulfilment of such a plan, must not be overlooked, in the exclusive right which some of the older proprietors possess, not only to their own salmon but those of their neighbours. Many *portions* of old estates have been sold to new families, the original proprietor reserving the right of salmon-fishing to himself and his successors. We believe, for example, that he who, in one sense, was the greatest man upon the Tweed, Sir Walter Scott, had no legal power to take a single salmon from the Abbotsford portion of the river, the "Royal Fish" being, by reserved right of ancient grant, the property of an old border family, the Scotts of Gala, who had in earlier times dispossessed themselves of the land eventually acquired by the great Magician. We believe the scheme could never be reduced to practice.[4]

Although all salmon deteriorate rapidly in fresh water, and are always the better-flavoured the nearer to the sea, or the shorter their time out of it, yet the sea-borne fish also decline greatly in condition by the close of the season. However, good individuals do continue to show themselves from time to time, which have not yet lost "all their original brightness," and these, of course, would bring a high price, supposing their capture and sale were legalized. The largest, and some of the finest of the late or winter running fish, are those called locally on Tweedside the "grey school." The lateness of their arrival indicates that they are also among the last to spawn. Though always late, they are by no means pointed as to the precise period of their advent, being guided, if not constrained, by the conditions of the river. They seldom show themselves till towards the close of November, and become more frequent in the course of the two ensuing months. Their arrival in close time, according to Mr Younger, in a great measure accounts for their large size, "escaping in their youth the nettings within tideway, unlike most of our other summer fish, and thus live to increase with age. Hence, if not our finest fish, they are at least our heaviest and most valuable, weighing from 12 to 25 lb. Hence, too, when they get early up the river, they are

[1] Blackwood's *Journal of Agriculture*, new series, No. 15, p. 505.

[2] It might be supposed that the bad condition of these fish would prove their safe-guard, and that although their capture may be often unavoidable, they would be immediately returned into the river. This was formerly and in some stations may be still the case; but in many instances they are sent off with their false fresh-water shine upon them to Leeds and other large inland towns, where there are many thousands of worthy people who have no knowledge of fish.

[3] Blackwood's *Journal of Agriculture*, No. 15, p. 506.

[4] The Duke of Roxburghe, and other great proprietors, would be enormously benefited by the removal of the commercial fisheries, but who could force them to share their increase with others, or to join with the general company of anglers, when they have already as much as they need, and are not asking for more?

The "grey school."

grand sport for the rod-angler, strong and fresh, like a grass-fed heifer a little gone in calf. It has a spirit-stirring effect to feel their tug, and see their first grand sally and plunge abroad in the river, at the end of a tight gut line." We do not agree with our author in supposing that these fish of the "grey school" constitute any special kind of themselves, or that there is anything in the habits of their early life that renders them less liable to fall victims to the ruthless net than their neighbours. They have not escaped in consequence of belonging to a particular school, but the converse is the case; and had they been sooner killed, they could not have been detected as belonging to any school at all. They have *chanced* to escape the net and other accidents by flood and field; but the chief cause both of their diminished lustre and increased bulk, is simply their having remained for a month or two longer in the salubrious sea than the rest of their relations. We have already said, that it is only among its marine pastures that any salmon grows. In a river it never increases at all except in ugliness.

Although the Tweed does not now open till the 15th of February (a fortnight later than all the more northern rivers), many think the time is still too soon. It is well known that on that day a great slaughter sometimes takes place at several of the netting stations, not only of kelts (or spawned fish), but of what are called *kippers* and *baggits*, that is, male and female unspawned salmon. Mr Stoddart states, that scores of ripe spawners have been captured below Tweed Mill during the opening week of the season, and that he has known of eighty she-fish, all large and primed with ova, having been taken in a single day from the Tweed near Twizel. In connection with this wanton waste of life, he makes the following very judicious proposal:—that the proprietors, or others holding salmon-fishings on that fine river, shall instruct competent persons to attend at the netting stations when the season opens, for the purpose of expressing and mingling the ova and melt of the unspawned fish, and immediately committing it to "redds" in the river, formed, in imitation of the natural places, by plow or spade. He opines, that for every clean or fresh-run fish taken in the Tweed for the first fortnight, there are at least a dozen of kelts, and four or five unspawned fish in a very forward or mature state. These are unavoidably captured by the same sweep of the net that secures the marketable fish, and therefore no extra expenditure would be required to obtain a great supply of spawn. There is here a vast amount of incipient life to be rescued from destruction, and which, if placed in properly prepared receptive beds of gravel, would eventually produce a great increase. Two hundred baggits, each yielding say 10,000 ova, would produce, supposing all were hatched, *two million* of fry, all vitalized at the expense of a few pounds sterling. Even supposing many of the eggs to be unproductive, and the greatest and most reckless destruction also to ensue of the future fry, still an addition might surely be relied upon of many thousands.

Mr Stoddart assumes the number of female fish which spawn annually in the Tweed to be 15,000, and he takes 10 lb. as their average in respect to weight. A ten-pounder is believed to carry 10,000 ova, and that number multiplied by the amount of fish, gives 150,000,000,—a very fair supply, as it seems to us, for the general market, if they all came to hand.[1]

Bull-trout of the Tweed.

The great abundance (as shown in our Tweed table) of that large species of sea-trout (*Salmo eriox*), called bull-trout, or Berwick trout, in the lower portions of the Tweed, is too remarkable to be passed without remark. The number taken on an average of many years back has been about equal to that of grilse, and about four times that of salmon. This applies to the river, while on the outward or coast fisheries it is quite different, the proportion of trout in these latter reaching to not more than a ninth of that of grilse, and a fourth of that of salmon. Thus by net-and-coble are taken three or four trouts for every salmon, while the fixed engines secure three or four salmon and nine or ten grilse for every trout. This curious disparity is explained by the local fishermen as follows. When a salmon or his aspiring progeny, a grilse, strikes the *leader* or shoreward portion of the fixed net, he follows close along its side till he voluntarily, though in ignorance, enters the inclosed chamber or trap, into which it conducts; whereas the bull-trout, whether naturally more acute and observant, or, for his size, of greater age, and, consequently, experience in the world, when he comes upon the leader, falls away backwards from, instead of submitting to, such treacherous guidance. He has thus an increased chance of eventually making his escape, at least from these marine dangers, by taking more outward bearings for his next approach. A glance at our table of the produce of the Tweed will suffice to show, that during the first quinquennial period, the average proportion of trout to salmon was as three to four, while during the later of those periods it was as four to one. This enormous change of proportion between the kinds of fish which the fixed nets spare and those they capture, has been noted as of "terrible significancy."[2] It has been found, that on an average of seven years the proportions of the three kinds above referred to, taken respectively by the shore and river fisheries of the Tweed district, is as follows:—For every 100 salmon, the shore takes 313 grilse and 34 trouts; the river 438 grilse and 333 trouts. For every 100 grilse the

[1] The quantities of spawn said to be contained in various fishes are probably in many cases assumed rather than ascertained. The general statement in regard to the species with which we are now engaged is, that a grilse, or a small salmon, contains about 5000 ova, and that a fish of 20 lb. contains as many as 20,000 ova. We have not ourselves acquired any precise knowledge of this matter from actual observation. The following statement, however, may be relied upon, as coming from the pen of an excellent sportsman and persevering inquirer, the late Robert Wallace, Esq. of Kelly:—"I went yesterday, 11th September 1848, to fish in the river Carron, which falls into the Dornoch Firth, where the counties of Ross and Sutherland meet, at Bonar Bridge. The banks showed evidently, by the footmarks along them, that the river had been closely fished before my arrival, and left but little prospect of much sport; and it so happened that I had not a rise till past four o'clock, after which I raised four fish in very shallow water, slightly hooking two, and killing one of the others, a small female grilse of only five pounds weight, nearly one pound of which was roe, already grown about the size of No. 2 shot; and this, be it remembered, in a small grilse, which many self-sufficient and very learned sportsmen insist are not breeders, although all really practical men, whether fishers or dealers in salmon, know quite well that grilse are even more early breeders than full-grown salmon. Well, the roe in my five-pound grilse counted no fewer than 3782 grains, and to the extent of that number I have marred the chance of a similar quantity of smolts going to sea, and returning free of cost of any kind, as a most delicious fish to eat, and a capital size to angle. The mischief I happened to do on the Carron has been done in a greater or less degree by every successful angler over all Scotland, including of course those on the Ness, and especially the fortunate captor of its annual boast, 'the big fish.' The law sanctions the destruction now universally complained of, so that those who act under it must not be found fault with; but the *law itself*, and those who doggedly maintain it, must bear the blame; thus raising the question, Should such a law remain any longer unrepealed?"

The following further statement on this curious subject is from Mr Foley of Lismore in Ireland. The left lobe of the roe of every salmon is larger than the right; and in his opinion the right and left lobes contain distinct genders of fish. On the 17th of September 1824, he took a 15-lb. female salmon, the roe of which contained 10,260 eggs. On the 16th of October he took a 10½-lb. fish, the right lobe of which contained 4612 eggs, and the left weighing 14 ounces, 4816 eggs.

[2] *Edinburgh Review*, vol. xciii., p. 356.

Bull-trout of the Tweed.

shore takes 32 salmon and 12 trouts, the river 23 salmon and 76 trouts.[1]

It is alleged that these sea-trout, or bull-trout, of the Tweed, prey upon the ova and fry of the true salmon; and it certainly appears from the above as if the Tweed salmon were diminishing, while sea-trout were on the increase. At the same time it is not easy to understand how the supply of grilse is not diminished in the same proportion by the destruction of the young. As sea-trout are not alleged to prey on grown grilse, it might naturally be supposed that a river well frequented by the latter would also in each successive season produce a corresponding amount of salmon; but it may be, that by means of a more skilful and assiduous mode of fishing a greater proportion of existing grilse are captured than in former years, and so the supply of salmon is diminished by two causes combined, viz., the destruction of ova and fry by the bull-trout, and an increased proportional capture of a diminished number of grilse,—that proportion still yielding the same supply to the market as before, but necessarily debarring the after occurrence of the old amount of salmon, which are the fish of the ensuing year. Whoever kills a grilse one season, destroys a salmon in expectancy for that which follows.

The destruction of salmon spawn by trout is strongly illustrated by the following extract of a letter from Mr W. H. Haliday. It relates to the capture of salmon in Galway, preparatory to the stocking of a small rill at Outerard with impregnated ova:—"A very curious fact was also ascertained in the course of this experiment. In taking up the spawning salmon we also caught a quantity of trout, and *in every instance we examined, save one,* these trout contained salmon ova, on which they were preying. From the gullet of one large trout we considered that 600 were by pressure ejected; and I retained this, along with a further quantity from other trout, deposited it in boxes isolated from the others, and found that a considerable portion of it came to life." Mr Buist confirms this destruction of ova by informing us of the fact, that the men employed upon the Tay in taking up the breeding fish secured a whitling or sea-trout, of not more than three-quarters of a pound in weight, and observed salmon ova coming out of its mouth. This fish being brought to Perth for examination, 300 impregnated salmon ova were taken from its stomach in an undigested state. "It may therefore fairly be presumed that this youngster had taken this quantity to his breakfast; and if he dined and breakfasted in the same style each day during the breeding season, it is difficult to estimate the expense of his keep. Such is the amount of loss of impregnated roe in one morning from a trifling fish; what must it then be throughout the season from the various enemies that it has to encounter!" Facts of this kind are the strongest arguments in favour of the breeding and bringing up in ponds, where food is plentiful and foes are few.

Mr Young, too, informs us regarding the voracious habits of the common river-trout. He has caught numbers during the spawning time, but never found one of them that was not full of swallowed ova. He adds, that their destruction is not confined to the ova, but that, as soon as the spawning process is over, they attack the fry of the river, and continue to feed on them until they take their departure to the sea. As an experiment, he put into a pond, one fine evening, along with a trout of not more than half a pound in weight, a dozen fine smolts of five inches long. When the pond was examined next morning, it was found that the whole dozen were devoured. Mr Young entertains rather peculiar, but in many respects, we think, well-founded views, regarding another supposed enemy of salmon. He thinks that otters, owing to the vast quantity of trout they kill, should be encouraged as much as possible in all salmon rivers, and is of opinion that these cunning creatures seldom kill salmon, and do so chiefly at a chance time, when the lochs and pools are shut up by frost, and they are induced to prowl into a still open stream. We know not exactly how this may be, but we remember distinctly more than once finding a good cut, consisting as usual of the caudal half, of grilse or salmon, left by the otter on the banks of northern rivers. "This animal fishes for sport often when food is not required, and when he falls in with a well-stocked pool he leaves dozens of trout upon the bank unbroken, which he never returns to eat; for when the river is open there is no difficulty of procuring plenty more, and at a cheap rate. And on the whole, when all circumstances are taken into consideration, in place of the otter being ranked among the salmon's enemies, we must give him the credit of being the first of their four-footed benefactors."

Modes of capturing salmon.

We shall conclude this portion of our subject by a brief notice of the different means employed in the capture of salmon. The principle upon which stake and bag nets are constructed is the same. Each has a lengthened arm called a leader, stretching for some hundred yards seawards of the high-water mark, and at right angles with the shore. The leader of the bag net has floats above and weights below, and conducts to an oblong bag or chamber of the same materials as to mesh, cork, and lead, but its walls are kept apart by means of anchor ropes at the quarters, and light staves a-top. Where the leader joins the bag there are openings (on the mouse-trap principle), narrowing as they recede, and admitting the salmon into the chamber, within which it may reside for a length of days without ever finding the narrow and now projecting slit by which it entered, and to which it presents its broad side as it swims around within its prison wall. These anchor nets are usually set in deep water, over rough or stony shores, upon the open coast, and are not left dry at low water. They are visited by boats at every tide, and their contents extracted. Stake nets are of greater extent, and more expensive structure. A leader of great length, composed of strong netting, supported by stakes, is stretched across a comparatively shallow shore with smooth bottom, and conducts to a staked and netted chamber, with easy though deceptive ingress. This terminal prison is often so placed as to be left dry at low water, and the fish are taken out by men entering the chamber when the water has receded.

The net-and-coble fishing is worked by one or more men in a small boat, making a semicircular sweep from the shore or bank outwards and downwards, paying out the net from the stern as they proceed. The upper end of the net continues to be held by men on shore near the point of departure, the boatmen ere long land again, and the two terminations of the net being brought together, the ground rope with its sinkers rather in advance of the surface one with its floats, the whole is drawn upon the shallow shore; the fish, if within range, being inclosed in a wall of net-work on either side, and finally captured in the purse-shaped form which the middle portion of the net assumes when it impinges on the shore. Each salmon as it emerges from the water gets one or two taps on the head with a stout stick, to put an end to any further contention or dubiety as to its ultimate destination. Lastly, *cruives* are traps constructed of

---

[1] If the increasing deficiency of salmon could be distinctly traced to or connected with the great increase of sea-trout, we should not hesitate to regard the advent of that decidedly inferior fish as a disadvantage, but if it is not in any way the cause of the destruction or disappearance of salmon, then, of course, its own abundance being admittedly of considerable value, must counterbalance rather than occasion the loss.

Irish salmon-fisheries.

stone walls set across a river with an intermediate chamber of wooden spars, into which salmon may enter, but from which there is no escape.

We shall now advert to a very important subject,—the salmon-fisheries of Ireland. Of these there has as yet been no proper historical or other exposition, and our own limited space, even if we possessed the requisite knowledge, would not here admit of our attempting to fill that great hiatus. All we can do is, to present a few miscellaneous notices, gathered from recent and authentic sources, such as the Reports and Correspondence of the Irish Board of Works.[1]

It appears that the salmon-fisheries of Ireland are to a far greater extent public property than those of Britain; and the public in Ireland, to a corresponding extent, exercise the common-law right of fishing in the estuaries and tide-ways. In Scotland there is a vastly greater amount of private rights, mile after mile of estuary and sea-coast being leased, and rents paid to individual proprietors. It is not so in Ireland—the exclusive individual or "several" fisheries there being few and exceptional; and for this reason it is probable that a different mode of legal regulation is required. Although royal grants of Irish fisheries were given from an early period, the royal prerogative was chiefly exercised by our James VI., who, on ascending the English throne, seems to have carried up with him the Scotch national view of the fishing franchise. Many of the *weirs*, though since transferred by patents to other parties, owe their origin to the church, in other words, they were encroachments by priors and abbots on the "King's Rivers." In the year 1537, when "coming events cast their shadows before," and the advent of the Reformation induced inquiry into the possessions of the monastic establishments, four high commissioners were sent over to Ireland to inquire into and reform abuses. It appears from a manuscript in the British museum (quoted by Mr Hore), that a jury of the city of Kilkenny presented, that "Item, the prior of Inystoke, the abbot of Jerypont, and divers others dwelling nere unto the ryver, doo make and set such weares from banke to banke in the same ryver, from Inystocke unto the mountayne of Bleme, that no ferye ne bote may have their course." Accordingly the act of 28th Henry VIII. was passed, reciting that "where at all times necessarie boates, scowtes, wherries, coltes, and other vessels, have been used to passe and repasse in the king's rivers of the Barrow, the Noyre, the Suyr, and the Rie, ... yet now of late divers wilful persons, having no respect to the premises, but more rather to their own wilfulnesse, singular commoditie, and benefite, have in divers places made such wires, purpressures, ingines, strictes, and other like obstacles, that by no means any boates, &c. can conveniently passe, and through which the salmon frie be cleerly destroyed, contrary to the effect and purport of the statutes therein provided;" and it was then enacted, that any person in company with the sheriff, or seneschal of the neighbouring shires, might ***prostrate and break down*** all such obstructions. It was also declared that a convenient gap for passage was to be made in every mill-dam.

"A remarkable feature," observes Mr Hore, "in the history of the river fisheries of Ireland is the amount of property obtained in them by the clergy, and by monastic foundations. Their claim, whether founded on that of the church of St Peter, or for the sake of enhancing their power in capturing an article of food, the use of which is enjoined by their creed, seems to have been universally recognised, whether on the part of the crown, the nobles, or the people; and to have occasioned the frequent establishment of those means forbidden by the laws, solid wiers or dams constructed across the entire bed of rivers, on the banks of which the seats of the church were more numerous than in any other country in Christendom."—*Inquiry, &c.*, p. 11.

Irish salmon-fisheries.

Ireland derives advantage, so far as her salmon-fisheries are concerned, from the comparative absence of great commercial cities, which so often injure the rivers on the banks of which they stand; and many of the tributary streams being clear and rapid, with a gravelly bottom, are well fitted for the production of these fine fish. The majority of the English streams are too slow and silent in their courses, are often artificially obstructed, and labour under disadvantage from the increase of civilization, which is against the superabundance of all creatures, of whatever kind, that require to be left in a great measure in a state of nature. The ancient Irish traditions point to the number of fish in the *invers* or estuaries; and it is characteristic of the country that the warrior Finn MacCool was *killed* by a fisherman of the Boyne *with his gaff.* His father-in-law, the monarch Cormac MacArt, was choked by the bone of a salmon. It is recorded in a tract on the O'Sullivan family, in the library of the Royal Irish Academy, that Mac Fineen Duff of Ardee was in use to receive L.300 per annum from the Spaniards for the liberty of fishing in the river of Kenmare. The value of some of these Irish fisheries, as producing an export trade, may be deduced from the *soubriquet* of O'Donnell, chief of Tyrconnel (now Donegal), who was called in Spain "the King of Fish," in consequence of the quantity imported in exchange for wine. The poet Spencer, in his *State of Ireland*, after bewailing the "lamentable desolation" and "utter waste" brought by civil war upon the province of Ulster, breaks forth into praises of the land:—"And sure it is yet a most beautiful and sweet county as any under heaven, being stored throughout with many goodly rivers, replenish'd with all sorts of fish most abundantly, sprinkled with many very sweet islands, and goodly lakes, like little inland seas, that will carry even ships upon their waters." "And lastly, the heavens most mild and temperate." In his *Faerie Queen* he takes note of many a river—of

> "The goodly Barrow, which doth hoord
> Great heaps of salmons in his deepe bosom."

And the—

> "Fair Suir, in which are thousand salmons bred."

The great poet also describes the "fishy fruitful Ban;" and, according to Pennant, 320 tons of salmon were taken at Coleraine in the year 1760.

There is no doubt that the great Irish rivers, with their numerous tributaries, if managed with judgment and assiduity, might be made of high commercial value. The Waterford estuary, though supplied by a less area than the Shannon, is the most important salmon-fishing in Ireland, as its entrance is not injured by a weir. We have no river in Britain comparable in capacity to "the spacious Shenan, spreading like a sea," and continuing open for boat-work, with short exceptions, for upwards of 200 miles above its entrance into the Atlantic.[2]

---

[1] Mr Wakefield takes some note of these fisheries in his *Account of Ireland, Statistical and Political*, 2 vols. 4to, 1812. Sir Charles Morgan has compiled an *Historical Sketch of the British and Irish Fisheries.* Mr John Finlay has given us a *Treatise on the Game and Fishing Laws of Ireland*, in 1827; and some useful information will be found in Mr Herbert Francis Hore's *Inquiry into the Legislation, Control, and Improvement of the Salmon and Sea Fisheries of Ireland*, published in 1850.

[2] The following table gives the areas of the catchment basins from which the principal Irish rivers and their tributaries derive their

Irish salmon-fisheries.

But for the weir at Limerick, the Shannon would be navigable for some distance above its site. The tide rises to a height of 12 feet on either side. The weir is made of stone piers, extending across the river like those of a bridge, and lath-work is stretched securely from pier to pier at the western side, or that on which the salmon ascend from the sea. To every alternate pair of piers there is lath-work affixed at the eastern side also, so as to inclose a complete chamber. There is an aperture for the salmon to get in, but none to let them out. Between the other piers there is no passage, so that when the salmon push their snouts against the lath-work they are forced to grope their way alongside till they get into "chambers," of which they have a short lease, though one for life. This weir stands continually, night and day, during the fishing season. It now has in its centre the *mona-rea* gap, or queen's share. Up to the winter of 1825–6 this obstruction was so formed that no salmon could pass, and it had not even the "middle passage" required by statute. It was carried away by the floods, and the lessee of the corporation of Limerick replaced it by the present contrivance. (See *Dublin Review*, vol. xi., p. 387.) Although the corporation had at one time claimed the exclusive fishing of the Shannon for a distance of 63 miles from their weir above the city, to the river's junction with the main sea (as granted by Queen Elizabeth), they afterwards restricted their claim from the "great Lax-wier, down the river, to a place examined by the viewers," namely, a castle near Cratloe-more, which is a distance of three or four miles westward on the river, and which has been but recently ascertained as the boundary. On this reservation the right of fishing was ruled in their favour. We believe its commercial value is much decreased. It formerly realized in certain seasons L.2500 a-year. At an after period (though before the introduction of stake nets at the mouth of the estuary) it still yielded an annual rent of L.1150. The lease of 1813 was for L.800 a-year, and the present contract (dated 1834) is for L.300 only, with a clause of surrender.

In all fishing questions there seems a tendency to partizanship. The word *rivalry* is supposed to be derived from *rivalis*, belonging to a bank. We believe that the legal rights of the corporation of Limerick to this great weir, whether by patent or prescriptive title of many hundred years old, cannot be questioned; but the obstruction it offers both to a free run of fish, and to the still more important purposes of navigation, is undoubtedly a crying evil, and one which ought to be lessened by every lawful means. It now stretches diagonally across the river, where the breadth of the stream is 1141 feet, and has only a single central opening, where, in summer, in consequence of a neighbouring bank, the water is so shallow, that a keel boat drawing only a few inches cannot pass upwards. It is built of stones, bound together by upright posts of timber, and does not quite touch the banks on either side.

There is no doubt that in various parts of Ireland stake nets and fixed weirs have, in opposition to the express provisions of the act of parliament, been erected in improper places, and even worked during illegal times. They have sometimes been re-constructed by the same parties after prosecution and conviction. In one instance of a very valuable salmon fishery, iron spikes were found so placed across the "free pass," or queen's share, as to prevent all upward migration; and in another case an endeavour was made to defeat the object of the statute enforcing that open space, by placing glaring substances within it, and particularly a huge uncouth figure *in the form of a crocodile*, to frighten the fish from going farther.

Irish salmon-fisheries.

Although not a few of the fishing privileges in Ireland have the sanction of a very high antiquity, many of the prescriptive claims to the powers exercised are of a more or less doubtful nature. The prevailing belief in Ireland is, that the law as it now stands (5th and 6th Vict., cap. 106, 1842) is in opposition to Magna Charta, and the common-law right. It has, in fact, been sometimes so declared by the judges, who have laid it down that notwithstanding that act gave permission to parties to erect Scotch weirs where the river was more than three-quarters of a mile wide, yet that neither that law nor any other can or does interfere with the common-law right, which is this, that no man can put up an obstruction, either to navigation, or to the passage of fish, in the king's highway, or in the tide-way. "With regard to the other portion of that clause which says that a person who has maintained a Scotch weir over twenty years, where the river is not three-quarters of a mile wide, shall be entitled to fish that weir, there again the judges have declared that that is illegal, inasmuch as it is a fixed engine, and an obstruction both to navigation and the passage of fish; and although the act of parliament does in a certain degree legalize it, yet it does legalize it against the common law of the land." (Evidence of the Earl of Glengall, *Report of Select Committee* in 1849.) There is no doubt that after the passing of the act of 1842 a great increase of fixed engines followed. The 22d section of that act permits the erection of fixed engines within one mile on either side of the mouth of a river, where the channel of the tideway is more than three-quarters of a mile wide at low water of spring tides, by persons not previously possessed of a "several" or exclusive fishing, either inwards or outwards of the mouth of a river less than half a mile wide. The exact position of what is to be deemed the "mouth" of a river, is to be defined by the commissioners. Their task is neither easy nor enviable.

Lord Glengall stated, in his evidence before the Commons' committee of 1849 (*Report*, p. 150) that great advantage would arise to the revenue of Ireland from the removal of obstructions in the rivers, and the suppression of poaching; and for this reason, that the moment the upper proprietors find that the fish ascend the river in the open season, and that they have a direct interest in protecting the breeding fish, they will protect them, just as they would their sheep or bullocks; but at present they feel little interest in the breeding fish, as those in good condition are "all taken by the Scotch weir owners." His lordship further informs us, that before the introduction of the Scotch weirs the Suir was, without exception, the best salmon river in Ireland. Fine fish, weighing 18 and 20 pounds, frequently ascended as high as 55 miles above Waterford; but soon after the Scotch system commenced very few salmon got up the river except during some heavy

---

supply of water. It is taken from Sir Robert Kane's *Industrial Resources of Ireland*, and was chiefly furnished by W. Mulvany, Esq., Commissioner of Drainage:—

	Total basin, square miles.		Total basin, square miles.

Irish salmon-fisheries.

floods. The Suir River Preservation Society was afterwards instituted, and as it was not only well conducted, but "as many as 27 of the Scotch weirs were prostrated," the fish not only ascended the river again for 55 miles as they used to do thirty years before, "but to our great astonishment we last year captured many fish of 30 and 25 pounds weight, 45 miles from the sea. Now, no man had ever seen a 30 or 25 pound fish for 30 years in those waters before." The case of the Lake of Killarney is also a curious one as regards the effects of fixed engines near the mouths of rivers. In former days the lake was full of salmon, and vast numbers of people resorted to that beautiful region for the sake of angling. It is chiefly the property of Mr Herbert of Mucross, and Lord Kenmare. For many years after the erection of Scotch weirs at the mouth of the river, scarcely any salmon ascended to the lake; but when the act of 1842 was passed, the proprietors of the lake were instructed how to proceed against the parties holding the weirs, and six of them were *prostrated*. One still remains, but, in spite of it, the lake is now remarkably well supplied with salmon.

The Irish salmon-fisheries are regulated chiefly by the act 5th and 6th Vict., cap. 106. It was passed in 1842, for the purpose of consolidating and amending the others then in force, and repeals all former acts relating to the salmon-fisheries of that country. The commissioners of the board of works are thereby constituted commissioners for the execution of the act, and have had conjoined with them two inspecting commissioners of fisheries. They are intrusted with a variety of important duties, and can make bye-laws for the alteration of close time, and its variation in different districts. The main object of the act of 1842 was to induce the capture of the largest quantities of fish, in the best condition, during the open season, consistently with the increase of the breed. It fixed a uniform close time, from the 20th of August to the 12th of February, to come into operation after the 1st of January 1844. It was not attempted to be enforced until after the 20th of August 1844, and was in truth but little attended to for some time afterwards.

In a later act, that of 9th and 10th Vict., cap. 14, which was prepared and submitted to parliament, in order to carry into effect certain regulations regarding close time, a clause was introduced in its passage through the House of Commons, whereby eight counties (viz., Antrim, Tyrone, Donegal, Londonderry, Mayo, Fermanagh, Leitrim, and Sligo) were exempted from the operation of the law.[1] This produced great confusion, and the Irish commissioners have since had applications from almost all those counties for the extension to them, *by bye-law*, of the benefits of the former close time, from which they were excluded by the clause just referred to.[2]

The annexed tabular view (see page 621), for which we are indebted to the kindness of Thomas F. Brady, Esq., one of the inspecting commissioners of the Irish fisheries, exhibits the exact state of the close-times of the various districts up to August 1855. We believe that some of the changes indicated in the table have been made rather with a view to meet the wishes of the individuals interested in the localities, than from a conviction on the part of the commissioners of their absolute expediency. But as the commissioners have the power, under the 35th section of the act, to rescind any order for change of season after three years, they are probably induced to allow persons to have their own way for a time, and not a few are said to have become convinced of their error from practical experience. The laws on the subject of the annual or weekly close seasons in Ireland are now very stringent, and the penalties for their infringement heavy. Assuredly they ought to be strictly enforced, because any wide departure from the legal principle is the more to be regretted in a country where so large a portion of the salmon and trout fishing is, by law, public property.

Irish salmon-fisheries.

For some seasons after the passing of the act of 1842, large captures ensued, and thus the practical operation of the amended law was to produce improvident destruction—nothing in the way of counteracting remedies being used to replenish or keep up the stock. Voluntary contributions having failed in their sufficiency to afford protection and remove obstructions, the act of 11th and 12th Vict., cap. 92, was passed (in 1848), authorizing assessment upon engines used in fishing, in order to create a fund for the purposes of preservation, to be administered by local boards of conservators, elected on a broad basis. This act did not come into operation till 1849, but it is now believed to be producing the desired effect. It also empowers the Irish board of works to divide the "Green Isle" into districts, and the recent arrangements will be seen from the annexed table.

The same variations take place in the Irish rivers as in those of Scotland, and the same somewhat contentious complaints are made by opposing parties against each other. The natives of the more upland streams bewail the unsparing and irresistible captures by sweep nets and fixed engines, while those who rejoice in, because they benefit by, the latter, are shocked at the unprincipled poaching and general want of protection which prevail in places where the spawning beds abound. The select committee on the fisheries of Ireland (1849) conclude their report by desiring "to record, once for all, their decided conviction, that the wholesale and wasteful destruction of the breeding fish and fry has materially injured the inland fisheries, and has excited and kept alive much local discontent, and demands the immediate attention of parliament, in order to the adoption of such alterations in the existing law as may be found expedient." In the minutes of evidence taken by that committee, Mr Ffennell, one of the inspecting commissioners, while referring to the advantages arising from a private protective association, and when asked, "Why did your association cease to exist?" replies, "Many persons found that they were going to expense, and taking a great deal of trouble in protecting the fish for the persons in the tideway, not one of whom would subscribe one farthing." Being asked, "to whom do you allude when you say 'persons in the tideway?'" he answers, "all the persons, the river owners, the cot fishermen, and every class of persons in the tideway; we found that we could get no subscription whatever from them, and that we were doing it all at our own expense, and that others were making the harvest. The large benefit of our protection must be to the tideway people, and it is there that the commercial value of the fish must always exist."

[1] An odd effect of these exceptions was that, for example, during a portion of the season, it was illegal to fish in *one* side of a river and bay in the county of Mayo, while it was legal to fish in the *other* side of the same river and bay in the county of Galway.

[2] The Irish Commissioners are appointed for the execution of the Fishery Acts by the 2d sect. of the 5th and 6th Vict., cap. 106, and the 2d sect. of the 11th and 12th Vict., cap. 92, and are empowered by the 33d section of the former, and 39th section of the latter act, to alter the close seasons in any river or district upon inquiry made and proof presented that such alteration is expedient. The 3d sect. of the 11th and 12th Vict., cap. 92, also directed the Commissioners to divide Ireland into districts, which they have done accordingly. That section, and the 6th sect. of the 13th and 14th Vict., cap. 88, conferred the power on the Commissioners to alter such districts, and to fix other boundaries, and to subdivide them as they saw fit. The districts of Bantry, Westport, and Londonderry have thus been subdivided, and so many alterations have been made in the close times (tending to uniformity) that Sligo, Fermanagh, and Leitrim are now the only excepted counties. In addition to these changes, the Commissioners have been called upon by persons interested in the fisheries of several districts to alter the seasons as fixed by law, and they have accordingly done so in the districts of Killarney, Limerick, Wexford, and Cork. Our tabular view will show these details distinctly.

Table showing the Close Seasons for Salmon and Trout in the different Districts in Ireland, as fixed by Statute Law, or the Order of the Commissioners.

No. and Name of District.	Counties or Parts of Counties comprised within District.	Principal Rivers in District.	Close Seasons for Net Fishing. By Statute Law. Tidal.	Close Seasons for Net Fishing. By Statute Law. Fresh Water.	Close Seasons for Net Fishing. By Order of the Commissioners. Tidal.	Close Seasons for Net Fishing. By Order of the Commissioners. Fresh Water.	Close Season for Rod Fishing, Single Rod and Line. Tidal.	Close Season for Rod Fishing, Single Rod and Line. Fresh Water.
1. Dublin	Dublin, Kildare, Wicklow.	Swords or Meadow Water, Tolka, Liffey, Bray, Vartry, Rathnew.	Sep. 1 to Jan. 31.	Sep. 1 to last day of Feb.	—	—	Sep. 29 to Jan. 31.	Sep. 29 to March 1.
2. Wexford	Wicklow, Carlow, Wexford.	Slaney, Baunow, Blackwater, Potter, Avoca, Courtown or Owenavarra, Sow.	Do.	Do.	Sep. 29 to last day of Feb.*	Sep. 29 to last day of Feb.*	Sep. 29 to March 1.	Sep. 29 to March 1.
3. Waterford	Queen's, King's, Kildare, Kilkenny, Tipperary, Waterford.	Suir, Nore, Barrow, Mahon, Stradbally, Dolligan, Colligan.	Do.	Do.	—	—	Sep. 29 to Jan. 31.	Sep. 29 to March 1.
4. Lismore	Cork.	Blackwater, Bride, Fuinisk.	Do.	Do.	—	—	Sep. 29 to Jan. 31.	Sep. 29 to March 1.
5. Cork	Cork.	Lee, Bandon, Carrigalim, Arrigadeen, Owenabuoy.	Do.	Do.	Electoral Div. B. Sep. 1 to March 1.	Electoral Div. D. Sep. 1 to April 1.	Elect. Div. A. Sep. 29 to Jan. 31. Elect. Div. B. Sep. 1 to Mar. 1.	Elect. Div. C. Sep. 29 to Mar. 1. Elect. Div. D. Sep. 29 to Apr. 1.
6[1]. Skibbereen	Cork.	Owenahinchy, Roury, Ilen, Leamavadarra, Ballydehob.	Do.	Do.	—	—	Sep. 29 to Jan. 31.	Sep. 29 to March 1.
6[2]. Bantry	Cork.	Ouvane or Ballylicky, Four Mile Water, Snave, Glengariffe, Adrigole, Maganigan, Dounemark.	Do.	Do.	—	—	Sep. 29 to Jan. 31.	Sep. 29 to March 1.
6[3]. Kenmare	Cork & a portion of Kerry.	Sneem, Sheen, Roughty, Blackwater, Clonee, Owenshagh, Croanshagh.	Do.	Do.	—	—	Sep. 29 to Jan. 31.	Sep. 29 to March 1.
7. Killarney	Kerry.	Laune, Maine, Carra, Curraun, Juny, Fartagh or Valentia, Carhan, Ownagare, Beagh.	Do.	Do.	July 31 to Jan. 1.	May 31 to Jan. 1.	July 31 to Jan. 1.	Sep. 30 to Jan. 31.
8. Limerick	Limerick, Clare, Westmeath, Longford, King's, Roscommon, and small portion of Leitrim.	Shannon, Cashen, Feale, Geale, Fergus, Maigne, Askeaton, Deel.	Do.	Do.	Aug. 13 to Feb. 11.	Aug. 13 to Feb. 11. Electoral Div. C.B. Aug. 13 to May 1.	Aug. 13 to Feb. 11.	Sep. 15 to Feb. 11.
9. Galway	Galway, and portion of Clare.	Corrib, Furboe, Spiddle, Costelloe, Ballinahinch.	Do.	Do.	—	—	Sep. 29 to Jan. 31.	Sep. 29 to March 1.
10[1]. Ballinakill	Galway, Mayo, and part of Clare.	Clifden, Ass or Errive, Delphi, Renvill.	Aug. 20 to Jan 31.	Do.	Sep. 1 to Jan. 31.	Sep. 1 to last day of Feb.	Sep. 29 to Jan. 31.	Sep. 29 to March 1.
10[2]. Bangor	Mayo.	Newport, Burrishoole, Ballycroy, Munhim, Owenmore, Glenamoy.	Do.	Do.	Sep. 1 to Jan. 31.	Sep. 1 to last day of Feb.	Sep. 29 to Jan. 31.	Sep. 29 to March 1.
11. Ballina	Mayo, and part of Sligo.	May, Owenmore, Easkey, Rathfran.	Do.	Do.	—	—	Aug. 20 to Jan. 31.	Aug. 20 to Jan. 31.
12. Sligo	Sligo.	Sligo or Garogue, Ballisodare, Dromore, Drumcliff.	Do.	Do.	—	—	Aug. 20 to Jan. 31.	Aug. 20 to Jan. 31.
13. Ballyshannon	Donegal, Fermanagh, Cavan, and Monaghan.	Erne, Bundrowes, Eask, Inver, Glen, Brackness, Ballydor.	Part Aug. 20 to Jan. 31. Part Sep. 1 to Jan. 31.	Part Aug. 20 to Jan. 31. Part Sep. 1 to last day of Feb.	—	—	Part Aug. 20 to Jan. 31. Part Sep. 29 to Jan. 31.	Part Aug. 20 to Jan. 30. Part Sep. 29 to March 1.
14. Letterkenny	Donegal.	Leenane, Gweebarra, Rathmelton, Farran, Buncrana, Ardara, Owenoocker, Owenea.	Aug. 20 to Jan. 31.	Aug. 20 to Jan. 31.	Aug. 1 to Dec. 31.	Aug. 20 to last day of Feb.	Aug. 1 to Dec. 31.	Sep. 1 to March 1.
15[1]. Londonderry	Londonderry, Tyrone, & portion of Donegal.	Glen Foyle, Roe, Faughan.	Part Sep. 1 to Jan. 31. Part Aug. 20 to Jan. 31.	Part Sep. 1 to last day of Feb. Part Aug. 20 to Jan. 31.	Sep. 1 to Jan. 31.	Sep. 1 to last day of Feb.	Sep. 29 to Jan. 31.	Sep. 29 to March 1.
15[2]. Coleraine	Londonderry, Tyrone, Armagh, Antrim, Monaghan.	Bann, Maine, Blackwater.	Part Sep. 1 to Jan. 31. Part Aug. 20 to Jan. 31.	Part Sep. 1 to last day of Feb. Part Aug. 20 to Jan. 31.	Sep. 1 to Jan. 31.	Sep. 1 to last day of Feb.	Sep. 29 to Jan. 31.	Sep. 29 to March 1.
16. Ballycastle	Antrim.	Bush, Ballycastle, Cushendum, Cushendal, Glenariff, Glenarm, Favre or Larne.	Aug. 20 to Jan. 31.	Aug. 20 to Jan. 31.	Sep. 1 to Jan. 31.	Sep. 1 to last day of Feb.	Sep. 29 to Jan. 31.	Sep. 29 to March 1.
17. Drogheda	Louth, Meath.	Boyne, Dundrum, Blackwater, Kilkeel, Castlewellan, Annagassen, Nannywater.	Sep. 1 to Jan. 31.	Sep. 1 to last day of Feb.	—	—	Sep. 29 to Jan. 31.	Sep. 29 to March 1.

* But for Fixed Nets 14th September to last day of February.

Irish salmon-fisheries.

The attention of the public, however, has recently been much directed towards Ireland and its capabilities, and an interest in the salmon-fisheries has evidently been on the increase from year to year. We believe the more they are considered the higher will their importance be appreciated as a branch of industrial occupation.

"And although," says Mr Ffennell, "an alleged decrease must be admitted to have occurred, yet some exaggeration prevails on the part of those persons whose interests have been diminished in value by the changes which have recently taken place in the capture of fish, and some miscalculations also arise in consequence of the more rapid and extended flow by which the tide of commerce, through the agency of steam, conveys the produce from local to distant markets. Proprietors of several fisheries sometimes judge the question of supply by the amount of their own capture solely, forgetful of, or misinformed on, the aggregate quantity captured by the many who fish outside, and which is there taken. The consumers in the principal towns, who, before the extension of railroads and steam navigation afforded means of cheap and quick transit to other markets, and before the facility of obtaining ice for its preservation at a reasonable charge existed, obtained salmon at low prices, complain of high prices, advance it as a test also of diminished supply, forgetting or overlooking the fact of the large quantity which is daily transmitted from their immediate vicinity to more remunerating customers in distant places. The grounds of disappointment and miscalculation are evident with regard to these classes, while others, who have been restrained by the enforcement of the law from undue interference with public as well as private rights, pronounce the alleged decrease in the salmon-fisheries of Ireland to be progressive in proportion as legislation has advanced for the purpose of meeting the evils complained of; and although the latter class may find some discontented persons, from selfish motives, ready to join in this too summary mode of disposing of the question, very many must conclude that it tends to mislead rather than induce a useful or disinterested discussion of the subject. Salmon having attained a price in the market as a luxury only available to the wealthy portion of society, and this increased value having stimulated a corresponding energy on behalf of the public to procure it for such profitable disposal, an improvident desire of over-capture has for some years been induced, which we believe to be the main point necessary to guard against and restrain. The ingenuity of man has also increased the efficiency of the means of capture, and the legislature having sanctioned the use of engines, under certain limitations, before restrained, at the same time, however, giving increased powers to protect; whilst the power to take has been injuriously applied, the intended equivalent of better protection has been too much neglected."—*Report*, 1852, p. 237.

Of course, the same nefarious practices prevail among the natives of the sister isle as with ourselves. The habit of "burning the water" is common in many of the wilder districts. The excitement of the sport, in addition to its productive nature, may be viewed as affording some excuse, but none can be offered for that deadly and altogether indefensible act of "poisoning" which is not seldom had recourse to. This is sometimes practised in Scotland by means of lime, a small quantity of which will destroy every fish in a pool. An equally opprobrious procedure is followed, too, in the county of Kerry. There, and elsewhere in Ireland, a species of spurge occurs in woods, and is called *Euphorbia hibernica*. It has a white juice, which may be extracted by pounding in a tub. If some of this liquid is thrown into a river when the water is low, the fish are killed for a considerable distance, and soon show themselves by floating on the surface. They are, unfortunately, not thereby rendered unfit for food; and when the country people hear that a river has been "poisoned," they assemble on its banks to share the spoil. Poaching is also carried on to a great extent, and, according to one authority, this has been greatly increased by the diminution of salmon during the open season.

"I remember," observes Mr J. D. Croker, speaking of the Blackwater, "when the river was so well stocked that the lower classes were universally permitted by the gentry to angle in every place without any obstruction. We found that by so doing we enlisted them, I may say, as bailiffs to protect the breeding fish in the winter, and that we had a sufficient *quid pro quo*. By and by, when their weirs were closed, and their mill barriers were shut up, the salmon decreased in the river in numbers, and the consequence was then, that the gentleman fond of angling prohibited, to a certain degree at first, those men who used before to be permitted to fish; and finally, I may say, they found there were so few salmon that they kept them for themselves, and in many places they were not allowed to fish where they formerly enjoyed the sport; the consequence was, that these fellows, when they could not get them in the summer, turned to poaching in the winter. When there is a flood in the river, and the weirs are open in the winter, they come up in thousands, and the destruction is beyond anything which you can conceive. The landed proprietors, finding that in the whole of the open season they had no fish, take no interest in preserving the spawning fish for the proprietors who have the monopolies at the mouth of the river; and I believe this to be the chief cause of the decline of salmon."—*Report from the Select Committee on Irish Fisheries* (1849), p. 36.

It is difficult to obtain actual data from which to ascertain the money value of the general salmon-fisheries of a country. In regard to those of Ireland, we observe it stated in evidence by Sir Richard De Burgo that he calculated the value of salmon caught by "every engine" (for the year 1847) to be close upon L.300,000. He had ascertained that there were L.18,000 worth caught in the estuary of the Suir, Nore, and Barrow. He put down the Shannon at L.20,000; and so on with the Lee, and other districts, however small. He applied to various parties for information regarding their own vicinity. "I then received from the same parties, as closely as they could give it to me, the number of rods, and every other engine that was used in their estuary, river, or in the entire district; and they fixed what they conceived the productive properties of the weirs, or whatever else the engine might be." It was thus that he made up his data. He regarded the above as a low estimate, and was of opinion that if some changes in the law were effected, and due protection afforded to spawning fish and fry, the Irish salmon-fisheries might be raised to the annual value of not less than L.2,000,000.

The following list, though imperfect, will show, at least approximately, the produce of the principal salmon-fisheries of Ireland, and will also indicate the names of the rivers, &c., where these occur. It was obtained in the year 1844-45, and applies to the quantities and value of that period.

Name of River.	Number of Fish, or money value, as far as could be ascertained.
1. Liffey	From 5000 to 7000 salmon, of an average weight of 7½ lb., was the produce of 1844; the average price was from 8d. to 1s. per lb.
2. Owenavarra	About L.140.
3. Slaney	About L.2000.
4. Barrow, 5. Nore, 6. Suir	About L.17,000 or L.18,000.
7. Blackwater	From L.3500 to L.4000.
8. Lee { Upper, Lower }	About L.1900.
9. Bandon	About L.170.
10. Ilen	About L.90.
11. Snave and Ballylicky.	About L.180.

Irish salmon-fisheries.

Irish salmon-fisheries.

Name of River.	Number of Fish, or money value, as far as could be ascertained.
12. Blackwater	About L.60.
13. Roughty; 14. Curraan; 15. Eenagh; 16. Carra; 17. Laune; 18. Maine	About L.7000.
19. Cashen	About 1500 salmon.
20. Feal	
21. Shannon { Upper... Lower... }	About 6000 salmon and 24,000 peal.
22. Corrib or Galway	4221 salmon; 10 tons average yearly produce.
23. Spiddal	About 400 salmon.
24. Costello	
25. Ballinahinch	5114 salmon, 34,747 lb.; 14,385 lb. trout, average yearly produce.
26. Benoyle Fishery	About 10 tons annually.
27. Delphi	610 salmon, 3847 lb.; 606 trout, 1417 lb., average yearly produce.
28. Errive, or Ass	60 salmon, last year's produce.
29. Killieries	Between L 300 and L.400.
30. Bellclare	L.18 or L 20 a-year.
31. Newport	In 1845 the produce was 8 tons salmon, and 3 tons trout.
32. Burrishoole	
33. Ballycroy	1841, 34 tons salmon; 1843, 21 tons; 1844, 24 tons.
34. Owenmore	About L.50.
35. Munhim	Between 2 and 2½ tons.
36. Glenamoy	23 cwt. was last year's produce.
37. Moy	
38. Easky	6 tons, 13 cwt., 3 qrs., 20 lb. last year.
39. Ballysadare	About 300 salmon yearly.
40. Sligo	7 tons, 7 cwt., 3 qrs., 2 lb. average.
41. Drumcliff	About L.30.
42. Bundrowes	9 tons, 18 cwts., 1 qr., 2 lb.
43. Erne	
44. Inver	1844, 753 lb. salmon, 2185 trout; 1845, 1242 lb. salmon, 1106 lb. trout.
45. Owentorker	
46. Owenea	
47. Clady	
48. Lacagh	1116 salmon, 7712 lb. average.
49. Rathmelton.	Average 9625 lb. salmon.
50. Foyle	About 82,000 salmon.
51. Roe	
52. Bann	51 tons, 1 cwt., 17 lb., average of six years.
53. Bush	10 tons, 6 cwt., 1 qr., 10 lb., average of four years.
54. Glyde and Dee	About L.600.
55. Fane	Between L.20 and L.30.
56. Boyne	

We anticipated the power of obtaining some detailed and accurate information regarding the pecuniary value of the Irish salmon-fisheries from the returns of the assessment laid upon them by the Poor Law Act. That such assessment must, however, be carried on in a very lax and careless manner, is evident from the fact that their total rated value, as laid before the select committee of the House of Commons in 1849, was only L.12,366, and even in that sum were included a few oyster and eel fisheries. It appears that the public fisheries, which comprise the chief portion of the tidal rivers, are not rateable. It must also be borne in mind that the rating is only upon what is fixed or stationary—no floating nets, draught-nets, sweep-nets, or such like, being charged at all. There are even many fixed engines not rated; because those who work them in the tideways do not do so as having any private right, thus gaining the benefit of a private property, but avoiding the poor-rate on the ground that it is public. But whatever may be the cause, there is no doubt of great neglect in the true valuation of the Irish fisheries under the poor law. The stake-nets, or Scotch weirs as they are called, are taxed at a certain sum whatever may be their productive value, and many of them are not rated at all.[1]

In the Report of the Commissioners for 1836, we have the following table, showing the produce of the Foyle fishery for 16 years prior to the introduction of the stake-nets:—

Year.	Number of Fish.	Year.	Number of Fish.
1808	14,837	1816	17,624
1809	14,413	1817	16,644
1810	17,145	1818	17,860
1811	9,601	1819	23,334
1812	19,285	1820	18,930
1813	14,375	1821	11,490
1814	18,434	1822	22,816
1815	20,630	1823	20,384
		Gross produce of 16 years	277,802

This gives an annual average of 17,363. In the same report we have another table, showing the take of the same fishery for 9 years preceding 1836, during which years the stake-nets were in full operation.

In 1827, the number of salmon taken was, in

		Stake-nets,	13,911	
...	...	Draught-nets,	32,090	
				46,001
1828,	...	Stake-nets,	13,070	
...	...	Draught-nets,	37,536	
				50,606
1829,	...	Stake-nets,	9,770	
...	...	Draught-nets,	23,000	
				32,770
1830,	...	Stake-nets,	30,957	
...	...	Draught-nets,	35,096	
				66,053
1831,	...	Stake-nets,	23,267	
...	...	Draught-nets,	39,293	
				62,560
1832,	...	Stake-nets,	31,497	
...	...	Draught-nets,	32,950	
				64,447
1833,	...	Stake-nets,	20,757	
...	...	Draught-nets,	29,580	
				50,337
1834,	...	Stake-nets,	20,575	
...	...	Draught-nets,	33,173	
				53,748
1835,	...	Stake-nets,	22,344	
...	...	Draught-nets,	33,562	
				55,906
Gross produce in nine years—		Stake-nets,	186,148	
		Draught-nets,	296,280	
			Total,	482,428

Annual average, 53,603.

[1] The following is the scale of license duties for each engine, net, instrument, or device used in salmon, trout, pollen, or eel-fisheries in Ireland:—

Single salmon rods	L.1	0	0
Cross lines and rods	2	0	0
Snap nets	1	10	0
Draft nets or seines	3	0	0
Drift nets	3	0	0
Trammel nets or draft nets for pollen	1	10	0
Pole nets	2	0	0
Bag nets	L.5	0	0
Fly nets	5	0	0
Stake nets or stake weirs (Scotch)	15	0	0
Head weir	3	0	0
For every box, crib, cruive, or drum-net in any weir for taking salmon or trout	5	0	0
For every gap, eye, or basket in any weir for taking eels	1	0	0

Other nets or similar engines, not named above, to have the license duties fixed by the Commissioners.

Irish salmon-fisheries.

In a subsequent report (1846), we have the following statement in relation to the six seasons, from 1839 to 1844, both inclusive:—

In 1839, the total number taken in the Foyle fishing was			43,181
In 1840,	...	...	59,305
In 1841,	...	...	52,582
In 1842,[1]	...	...	82,106
In 1843,	...	...	62,348
In 1844,	...	...	49,337

It appears from the preceding tables, that while the annual average of certain seasons prior to the introduction of stake-nets was 17,363 fish, the smallest number taken in any one year afterwards (that of 1839), was 43,181, of which 23,934 were taken by means of draught-nets alone, being 6571 more than the average of those nets in earlier times. It further appears, that while in 1830 the produce of both kinds of nets was 66,560, that of 1842 was 82,106; so that after fifteen years working of the stake-nets, the quantity taken by both means had increased. The report for 1836 is headed—"The product of the Foyle salmon-fisheries has increased very much within these last ten years, in consequence of the introduction of stake-nets, and an improved mode of fishing with draught-nets; also, by establishing a more vigilant and effective system of water-keeping." We doubt not that the productive powers of these fish are so great, that if the fry (parr and smolts) are effectively protected while in the river waters, a great increase of captures may be looked for. The practice of preserving the fish in ice, and the enlarged facilities of transmission by steam-boats, have no doubt increased the value of salmon in Ireland as elsewhere; and Loch Foyle being a fishery of the "Irish Society," that company is believed to have added to its protective staff, and exercised greater activity and vigilance in watching the spawning grounds, thus ensuring an increased take and a larger income.

The following particulars, which further illustrate the value of the Irish fisheries, may be gleaned from the various reports by select committees of the House of Commons (1824–25–27–36). Mr Little, one of the principal lessees of the north-western stations, stated that the fish from each of the rivers Bann, Foyle, and Moy were worth at least from L.5000 to L.6000 per annum, and in some years from L.8000 to L.9000. The sale of salmon caught in them during 1835, amounted in Liverpool to L.9000, in Manchester to L.5000, in the neighbourhood of the rivers themselves to L.1800, besides considerable consignments to Dublin, London, and Glasgow, the total being nearly L.18,000. The annual produce of the Foyle for nine years prior to 1836 was 53,603 salmon, weighing above 140 tons, and worth nearly L.17,000. The quantity of salmon shipped by Mr Little and his partner to Liverpool, from their fisheries on the Bann, Bush, Foyle, Ballina, Ballyshannon, and Port Rush, from 1808 to 1823 (including shipments for the last year to London, Bristol, Glasgow, and Whitehaven), was somewhat over 2134 tons 14 cwt., which, at a shilling per pound, made the sum of L.239,141, 3s. In some seasons the Port-Rush fishery produced 18 tons of salmon, the Bush 15 tons, the Moy, at Ballina, 100 tons, and the Ballyshannon 90 tons. When such is the value of these comparatively small fisheries, which are nothing like those of the Shannon, Kenmare, and Blackwater, it has been inferred that the value of all the fisheries from which the public are now excluded cannot be under L.500,000 a-year.[2] So plentiful were salmon at one time in the Bann, that, according to Mr Finlay, 1400 have been caught at a single haul, and 1000 at the succeeding one.[3]

Irish salmon-fisheries.

Mr Christopher Keays, who had been for twenty-two years connected with the fisheries at Killorglen on the Laune (the Killarney river), used to pay from L.5000 to L.6000 annually for the fish he bought, including the price of the Waterville fish. The prices were, for spring fish 1s. per pound, for summer fish 3½d., and for May fish 6d. He had five or six ice-houses, and did not require to import that material. He sent the fish to England packed in ice, and sometimes pickled. Got the greatest number of good spring fish in April, and of grilse in June. In the year 1834, the greatest number he got from the Carra was in December, and they were in the finest condition. "The nearer the fish to the sea the better. The fish begin to loose their curd as soon as they go up the fresh water." We shall here give the monthly produce in weight for four successive seasons.

Amount of salmon purchased at Killorglen by Messrs Keays & Ronayne for the years mentioned:—

More than L.4000 worth of salmon were taken in the Slaney in 1842; and a Scotchman of the name of Hector, an experienced owner of bag-nets at the mouth of the estuary, stated in evidence that if properly fished and efficiently protected, it might be raised to the value of L.7000 per annum. The river Moy fishery is rated to the poor-law valuation at L.1768, 15s. a-year, although it is believed on good authority to be worth L.4000. The annual expense of protecting the Moy, Bann, and Foyle amounted to L.1500 or L.1600. There were four hundred men employed as keepers, and yet many of the tributary streams were left unwatched. The lessees complained of this expense of protection, which was a tax nearly equal to the rent. However, the amount of sales of salmon from these three rivers amounted during the preceding year to L.17,450. When the native supply of ice failed, the cost of importing that indispensable material from Norway amounted to L.1500 a-year. Prior to the year 1824 employment was given by that fishery to 800 people. In consequence of increased preservation the production rose. The annual average produce of the Foyle, for sixteen years before the introduction of stake-nets, had

[1] The season of 1842 was an excellent one for the salmon-fisheries in general. During that year nearly 110,000 grilse were taken in the lower portions of the Tweed. No season was so successful within our recollection since 1816, in which these same fisheries produced above 120,000 grilse. The year first named was excellent also in the Tay, the Kinfauns fisheries having yielded above 21,000 grilse, or nearly double the average of that time. A productive salmon season may arise from one or other of two causes, or both combined. It may depend on a preceding spawning time having been unusually favourable, or upon the weather during the season of capture having been advantageous for the working of net and coble, and the ascent of fish from the sea.

Irish salmon-fisheries.

been 17,363 salmon, weighing about $43\frac{1}{2}$ tons. The produce for the last nine years (Commissioners' Report for 1846) had been 53,603 salmon, weighing above 140 tons; so that in addition to an increase of about fifty per cent. in the quantity taken by the draught-nets, nearly as large a take as in former years by these alone was made by the then newly introduced stake-nets. Thus the produce of the Foyle alone was raised from an average, prior to 1823, of 43 tons, to a steady return of nearly 200 tons, and in the great year of 1842 to close upon 300 tons. The numerical produce that year was 82,106 salmon. According to the evidence of the agent of the lessees, the entire produce of the river during the first year of his management was 39 tons. He commenced protecting, and three years afterwards the yearly return rose to 100 tons, and the average produce of seven years is now (evidence given in 1845) 140 and odd tons. It is stated in Lord Strafford's *Letters* (1638), that the fishery at Derry (that of the Foyle) produced to the crown in that year 240 tons of salmon, which sold at L.15 a ton, "so as I hope, the charge of getting, salting, and packing the fish, deducted, there will be cleared at least L.1400, while it was never let for above L.1000 before, so as his majesty, you see, will come by no loss the whilst." By modern protection it is again approaching the limit of its ancient produce.

Return of the quantities of raw and manufactured salmon exported from Cork by the establishment of Mr John Christopher Keays. The fisheries embrace about a mile on the Clare shore, from near Money Point to Clonderlaw Bay; and on the south, from a mile on the other side of Tarbet to Foynes, including a range of 12 or 14 miles. There are eleven stake-nets.

1842.—*Exports, extending over a period of ten months.*

During these twenty-one years they always fished in the same manner. The return includes the entire take. They fished in the tideway, but not below Salter Bridge. The greatest run of early fish the lessee ever had was in the month of February 1844. On the opening day of that season (14th of the month), 288 fish were captured, weighing 2311 lb. The weekly close time had been strictly observed in 1843, but those conversant with the locality do not consider that the increase was produced by that observance, but rather by the fact that the Scotch weirs further down were not in fishing order. From 1823 up to the passing of the act of 1842, the close time was not strictly attended to. They used to catch in the month of December the most delicious fish of the year. This seems a parallel case to what has been stated regarding the Ness, and some other northern rivers.

The Moy presents a fair example of the good effects of protection. In 1811 half of the lease was purchased from one of the holders, but the partners were "bad friends," and one of them would not concur in the expense of watching. The quantity of fish taken that year was only 6 tons 4 cwt. This condition of affairs continued until 1815, when the lease falling wholly into the hands of the new proprietors, they immediately appointed water-keepers, and in the following year were rewarded by a take of 42 tons. Since that time, 100 tons have been killed in a single season, and the average has been 60 tons; so that an increase of ten-fold "arose from the protection afforded to the mother fish."—*Evidence*, of 1824. The Newport river affords similar and more recent testimony. After the passing of the act of 1842, Sir Richard O'Donnell, being sole proprietor of this small river in the county of Mayo, took advantage of the provisions of the act, and paid liberally for the protection of the fish. In the course of three years he raised the produce from a ton to eight tons of salmon, and three tons of white trout, for the season ending the third year.—*Evidence* in Fourth Report, 1846.

The produce of the salmon-fisheries of Ireland (as elsewhere) for 1850 was about the least upon record. We find its failure foreseen and predicted by Mr Caulfield, superintendant of the Hon. Mr Plunket's fishing in Killevy Bay, situate in a mountain district. The following letter was addressed by him to the commissioners :—

"I beg to call your attention to a letter written by me on the 4th of March 1848, in which you will find that I predicted that many persons would be disappointed in the take of salmon in 1850. The spawning season ending January 1847 was very bad from the time the salmon began to deposit their spawn. One flood was higher than another, tearing away bridges, the banks of rivers, the spawning fords, and, in some parts, covering those fords with a depth of gravel scarcely credible. Since I came here, I never saw so many floods in the spawning season. I am fully convinced then that the greater portion of the spawn were swept to the lakes and sea, and became the prey of other fish. You will remember that I stated that this would not tell till 1850, for I was convinced, and am now a greater dogmatist in my own opinion than ever, that we would take very little salmon under two and a half years old. For instance, the fry spawned in November 1847 remained in fresh water till May 1850. They remain at sea three or four months before they return to the mouths of the rivers they had forsaken when fry, and then weigh from six to seven and eight pounds. You will see that this would be exactly allowing the fish spawned in December 1847 to be killed in June, July, and August 1850. I said in my letter of 4th March 1848 that the decline of our salmon-fisheries began with the change of our winter seasons from frost and snow to continual rains, causing high floods, and these floods happening invariably in the months of November and December when the fish are spawning. In December 1847,

during the spawning season, stones above twelve tons weight were carried from the top of the spawning fords above fifty yards down the river by the strength of the current. Where then must the small pea of a salmon, dropped in such a current, have gone, even if it had reached the bottom of the pit where the mother fish intended to deposit it? When our salmon-fisheries were productive, the month of December was what we call a hard month, freezing all through. It is a fact well known to all experienced in the nature of salmon, that in the month of December the greater bulk of the fish spawn, and if freezing then, the fish will come into the fords at night and make the ruts in water not above six inches deep. Here the mother fish begins to drop the spawn, and gets them all deposited, as there is no current to carry them away. One salmon will get more pea deposited in low water than sixty in high floods. In 1847, during the spawning season, baskets full of the spawn could be gathered along the shores at Bundurra, where the preceding tide had left them in the sea-weed. Now, as I have ventured to predict for 1850, I will again venture to predict for 1851 and 1852. The spawning season of 1848 was passable. There were some high floods, but not many that I could call destructive. In 1851 there will be a reasonable take, leaving proprietors and lessors of fisheries fully satisfied that the fisheries have all much improved. 1852 will convince every one that the salmon was not devoured by the renowned sea-serpent."—*Report*, 1851, p. 115.

The origin of this deficiency in 1850 has led to some discussion; and those who maintain that it may be traced to the unfavourable conditions of the spawning season of 1847, of course do so in accordance with Mr Shaw's view, which is, that the ova of that year would produce the grilse of 1850. "That the deficiency in the salmon-fisheries of last year," say the commissioners in 1851, "was mainly produced by natural causes in the spawning season of 1847, is admitted by most persons to whose opinion weight can be attached, and is in some degree confirmed by the improvement in the fishery of the present year referred to in the report of the inspecting commissioners." It is wisely added elsewhere, that if the means and times of fishing be strictly limited to those fixed by law—if suitable passes be made for the migration of fish, and the Sunday or weekly close time be enforced on all coast fisheries, as well as in the estuaries and inland waters—and finally, if the capture, possession, or sale of fish, during close-time, be effectually prevented by the authorities, no doubt need be entertained that these fisheries will obtain a great development.

While discussing the Scotch salmon-fisheries we referred to the subject of drainage disparagingly, as if that agricultural process were often of piscatorial disadvantage. It seems to be otherwise in Ireland, where the system of arterial drainage, and the improvement of the navigation, have been of service.

"To some," observes the inspecting commissioner, "it has appeared anomalous that the fisheries should be benefited by works of drainage, but the experience already obtained fully justifies the anticipations which were formed on this subject. In cases where works have been executed at the mouths or tidal parts of rivers, the deepening and confining of the channels through extensive flats to the seas, and the extension of the tidal influences on brackish water inland, have afforded facilities for the salmon and white trout to enter the rivers; whilst the formation of improved migration passes over obstructions, and the regularly deep channels have facilitated the access of the fish to the upper waters and breeding grounds. The floods, too, in rivers that have been thus opened are much more frequent, though small in amount, than in an undrained country; and where, as in Ireland, the river-courses have but very little fall, and there exist numerous lakes and deep reaches of the river at the back of mill and navigation weirs, the migration of the fish is not only facilitated but promoted, whilst the increased discharge of water into the sea conduces to the capture of the fish by leading them to the rivers. These results have been proved practically in the lower Bann at Coleraine, where the fishery has been importantly increased, at the Fane near Dundalk, the Glyde and Dee, county Louth, and the Balleyteige district, county of Wexford, where salmon and trout were almost unknown before the execution of the works, and where, in addition, large quantities of herrings and other fish have for the last two years been taken within the bar or mouth of the estuary. But in the cavernous limestone districts of the counties of Galway and Mayo still more interesting experience has been obtained. In these districts where very large portions of the waters were discharged by cavernous passages, and through interstices in the strata too small to admit the passage of fish, and where in summer no water was discoverable as flowing from very large tracts of country, very important changes have been effected. In the Lough Corrib and Mask district, lakes containing more than 30,000 acres of water, and rivers and their tributaries more than eighty miles in length, have been opened for the first time to the free access of the salmon, by means of long and deep cuts through rocks, which were required for the drainage of the country, and which as they become completed afford constant streams of water even in the summer season. The salmon have already been taken in the upper waters of these districts, and it would be difficult to estimate the benefits which in a few years may naturally be expected to result from this improved means of access and increase of spawning ground to the fisheries of the districts."

The rivers Dee, Glyde, and Fane, in the Drogheda district, are stated by those who fish in them to have been much improved by the drainage operations. The removal of shoals has enabled the fish to ascend, and more fish have been captured both by the net and the rod than for many preceding years, and the salmon have reached a distance in the upper waters before unknown.—*Report*, 1852, p. 240.

The completion of the works under the drainage acts at the fishing weir or *cutts* of Coleraine, by which the original construction has been altered and improved, has afforded to persons fishing in Lough Neagh and the upper waters an increased supply of salmon, which, while it is not more than equitable to the upper proprietors, will ultimately much increase the value of the lower fisheries. The eel fisheries of the Bann are held by an Englishman, and produce a rent of L.1150 per annum. The salmon-fisheries of the Foyle and the Bann were taken in 1851 by a merchant in Londonderry at a rent of L.2400 per annum.

The principal fishery of the Sligo district, in the town of Sligo, was leased in 1851 to some experienced Scotchmen, who worked it with energy, employing during the close season forty water-bailiffs well armed, and who afforded a salutary protection to the breeding fish. The commissioners were informed in the ensuing spring that the capture of large fish returning from the sea (and which otherwise would have been destroyed in the upper waters) had even then repaid the outlay.

The advantage of improving the salmon-fisheries of Ireland is indicated in the following notice regarding the Bangor district. "The supply of fish here has been very good, and the fresh waters, many of which are occupied by anglers who pay for their amusement, have not disappointed the followers of the gentle art, whose visits to the wilds of Erris are of much more importance than may appear to a cursory observer, inasmuch as that several who have been first induced to visit this remote part of the country to seek for amusement, have either themselves become owners of land, or induced others to purchase, and the sale of property has been considerably assisted by this attraction."—*Report*, 1852, p. 241.

Irish salmon-fisheries.

There is no part of Ireland more interesting, in relation to its fisheries, than the Galway district. We there find two great several or exclusive commercial fisheries—one at Ballinahinch, occupied by Mr Robertson, who has been in use to pack and preserve his fish in tin cases, for exportation to foreign countries; and another called the Galway Fishery, which was sometime ago purchased for the sum of L.5000 by Mr Ashworth, an English gentleman of wealth and enterprise. The rivers Costelloe, Gowlaun, Inver, and Spiddal are occupied by noblemen and gentlemen, who spend the greater portion of the summer in the wilds of Connemara, producing even by that temporary residence great benefit to the people employed. The large lakes of Corrib, Mask, and Ballinahinch, are open to the angling tourist, and their being so induces many to dwell for months by the side of those sweet waters. The navigation and drainage operations, under the board of works, tend to develope the natural resources, and consequently increase the commercial and other value of these fisheries, by connecting the Lakes Mask and Corrib, and so enabling the fish to ascend to the former, from which they can command an enlarged field of spawning ground, previously unprofitable. The clearing of rivers tributary to those lakes, and the formation of upward passes wherever natural obstructions are found to occur, will perfect such important works. Much benefit may be anticipated from the exertions of Mr Ashworth and his local agent.

In our observations on the Scotch salmon-fisheries, we alluded to the alleged advantage of economising the modes by which fish are captured. This is a mixed problem in political economy which we shall not here seek to solve. The natural tendency in all things seems to be towards simplification in connection with discovery or improvement in the mechanical arts. The occupation of the copyist and illuminator of MSS. disappeared or diminished on the spread of printing, but probably far more printers are now employed than were ever penmen of any kind in earlier ages. The following is an Irish writer's view of the bad effects of the mechanical improvement or invention in the art of net-fishing, that is, working by means of *fixed* machinery.

"It is not only in enhancing the price of fish to an extravagant amount, and rendering the fisheries utterly insignificant compared with what they might be under other circumstances, that the monopolists inflict the greatest injury on the people at large, but in the mode in which they carry on those fisheries. Were the public right of fishing in these waters allowed to be exercised, every one who could command a rod or a net might go out and fish when and where he liked best, and thus thousands might amuse or employ themselves according to their tastes or necessities; but under the present system things are managed otherwise. In the fishing seasons the salmon go up from the sea towards the fresh-water rivers. Instead of employing a number of men to pursue them in boats, with nets or lines, in their progress along the monopolised coasts, bays, or rivers, the patentees or proprietors fix down weirs at the narrowest points nearest the fresh-water streams, extending generally in bays and rivers from shore to shore, and on the coasts of the sea as far as possible into the tide. These weirs secure all the salmon that attempt to pass them, and at the ebb of the tide three or four men take them out of the nets or chambers, and bring them ashore. Thus a weir and three or four men deprive perhaps ten thousand people of legitimate and profitable employment. Of the actual numbers thus debarred from employment, the reports before us give no return or estimate; nor have we been able, though we have spared no efforts, to obtain any from other sources; but, to enable the reader to form some conjecture on the matter, we shall state the facts which have come under our observation with regard to the only two rivers respecting which we have been fortunate enough to ascertain any particulars of this nature. According to the report of 1836, there is no part of Ireland in which the rights of the public to fish in the sea and tidal rivers seems to be so well understood and generally exercised as in Wexford. Yet the commissioners, who in this instance only condescended to hear any evidence but that of the monopolists, adopting the statements of the fishermen, say—'The present laws appear to be very strict, and passed as if intended to protect the employment of the fishermen from the encroachment of the gentlemen and weir-owners; but it is quite evident that these laws have remained a dead letter for the last century. The gentlemen and managers who should enforce them became weir-owners, and in the receipt of large revenues therefrom, allowed the fishermen, who were thirty years back a comfortable, well-clad, well-housed, people, to dwindle away into wretchedness and poverty,' though the salmon-fishery, if properly and legally managed, would 'give ample and well-paid employment to one thousand five hundred people for six months of the year.'—*Report*, p. 66. The report does not say, but we suppose, that the herring, mackerel, and other fisheries, would employ them during the remaining six months. The Shannon is 214 miles long from its source to its mouth, and navigable throughout all that extent except for a few miles between Limerick and Killaloe, and a few miles more near its source. It passes through several large inland lakes (one 14 miles by 10); is affected by the tide for 64 miles; is 9 miles wide at its mouth; for 40 miles has an average breadth of 3 miles; and for the remaining 24 miles gradually narrows to something less than a quarter of a mile at Limerick. About 2 miles above Limerick the corporation erected a weir across the channel from shore to shore. This weir was so constructed that not a salmon could pass through or over it. Between it and the main sea the corporation would not allow any one to fish, and between it and the source of the Shannon they of course did not allow a salmon to appear; and thus all the fishing in the river was confined to that one spot, and was managed by five men, four to take the fish out of the weir, and the fifth to kill and count them. Had that weir been indicted and abated as a nuisance, and all other illegal weirs and fixtures along the course of the river been removed, and all persons been allowed to exercise their rights of fishing, and in a lawful manner only, there would have been 'ample and well-paid employment' afforded to at least 40,000 persons."—*Dublin Review*, xi., p. 364.

A bill was introduced into the Irish parliament in 1784 for the promotion of the Irish fisheries, and one of its clauses provided that in each weir in the Shannon there should be fixed a sluice or flood-gate, of six feet in width; and that it should be left open from Saturday evening to Monday morning to permit the fish to ascend the river to spawn. This bill was lost, but a few years afterwards another was brought in and passed. It provides that in every weir in every river, and in the deepest part of that river, there should be a passage 21 feet wide, called the "king's gap," left always open. It is said that this statute has been in most cases disregarded by the weir-owners, and the Limerick corporation for a long time set it at defiance, till legal proceedings were taken against them.

Observations on the subject of bag-nets have been made by the Inspecting Commissioners of Fisheries in Ireland:—

"The use of these engines still continues to be a subject of complaint on the part of those whose interests lie inside their sphere of action, and many allegations are made with respect to the injury which they are said to occasion. It is asserted by some that when they intercept the free run of fish in their courses by the shore, seals and porpoises take advantage of the difficulty of escape thus occasioned, and seize them in large quantities during the confusion caused by these impediments; while others maintain, that when

Irish sea-fisheries.

placed near the entrance of rivers they turn the fish to sea, and prevent their approach to the inner water; and while we are disposed to concur in the latter proposition, to a certain extent, during calm weather, and in clear water more particularly, we are not prepared to pronounce a decided opinion one way or the other upon the correctness of the former. We regret, however, to be obliged to state that the owners of bag-nets in too many instances provoke the hostility of rival parties by neglecting to comply with the law in respect to weekly close season, and some more unreasonable than others have gone the length of remonstrating against the enforcement of this salutary regulation; but in every instance of this nature which has come to our knowledge we have recommended the penalties of the law to be inflicted, and have refused to sanction any relaxation of its provisions with respect to removing the leaders of the nets, and have on many occasions called the attention of the coast-guards to the authority with which they are invested for the prevention of such offences."—*Report*, 1852, p. 239.

Having now, with greater amplitude than we intended, discussed the subject of the salmon-fisheries in their natural, legal, and commercial bearings, we shall proceed to the sea-fisheries, properly so called, and may as well commence with a notice of those of Ireland, so as to finish what we have to say of the aquatic resources of that portion of the kingdom.

If the sea-fisheries of Ireland are defective in the way of production, this is certainly in no way owing to any deficiency of natural supply, but rather to the industrial spirit of the people not having been successfully and continuously exercised. Some improvements were at one time manifested; but the "famine years," instead of leading to more active exertion, produced the contrary effect. The employment of the people under the labour rate acts, when the average number relieved by daily labour from Oct. 1846 to June 1847 was 356,000 men (the prodigious host amounting at one period to 700,000 persons) however necessary it may have been deemed at the time, had a deleterious effect. Some scarcity of sea-fish is alleged as regards the eastern waters, but this must be principally in those where the poorer fishermen with insufficient gear are known to congregate; for the English trawlers, who fish the deeper waters, and are better appointed, make no complaints. Mr Bartlett acknowledges a steady profit of 30 per cent. upon his outlay. The Nymph Bank, off Waterford, is famous for both the quantity and quality of its white fish. The same observation applies to the fishery of herrings. These fish are said to be less abundant than formerly off the Irish coasts, but they are nevertheless met with by those boats that stand out into deeper water.

When the establishment which had been formed by government in 1819, for the promotion of the Irish fisheries, was dissolved in 1830, it was found that around the coasts of Ireland there were 64,771 fishermen, and 13,119 fishing-boats. In 1836 there were, according to a carefully revised enumeration made by the officers of the coast-guard, only 54,119 fishermen, and 10,761 boats. "This decrease," observe the commissioners, "of 10,652 in the number of persons occupied in supplying fish for the markets of an increasing population occurring so suddenly, while the consumption of all other domestic supplies has been considerably augmented, and in a period during which the markets of Liverpool and Manchester have largely increased the demand on the industry of Irish fishers, is a lamentable fact, too plainly indicative of much local suffering. It appears, however, that at the appointment of the late fishery board, the total fishing population of Ireland amounted to but 36,000, and that during the short course of its activity the numbers increased to nearly the double. Hence it may be inferred that the subsequent falling off must, in part at least, be a result of some previous excess of stimulation; and that the bounties had indeed drawn more persons to this branch of industry than in the then condition of the country were really enabled to support themselves by its exercise without government aid."

It was found, on inquiry, that the fishermen of Ireland generally occupied small portions of land, and often depended for subsistence on that source more than on the sea, their condition being thus mainly determined by the local circumstances of agriculture. Although great distress was too frequently apparent, it was ascertained that the well-equipped and skilful fisherman was able to support his family, independent of the land, on a scale of comfort superior to that of other labourers. It is now distinctly understood, from the experience of the Scotch fisheries, that where there exists a facility of transport to large markets, the sale of fish in a fresh state is safer, and for the most part more profitable, than after they have been cured. Under the existing conditions of some of the remoter coast districts of Ireland this ready market cannot be yet obtained; and when the almost nominal price which a poor though hard-working fisherman sometimes obtains for the produce of his night's labour is considered, his depression and apparent indolence can scarcely be wondered at. The inspecting commissioners inform us that "fine haddocks are now (April 1849) offered at Belmullet for 6d. per dozen." And Mr Wade, a person of experience, who superintends a fishing establishment in Galway, states (in May 1855) that a crew of four men, after having taken forty large turbot in a single shot of their lines, will sometimes have to row them to market 16 miles through a heavy sea, and sell the whole lot for 25s. Yet, that the general quantity of fish, whether fresh or cured, obtained from Irish fishermen is insufficient to meet the demands of the country, is obvious from the quantity of salt herrings imported from Scotland. Wick herrings are found on sale in the great majority of Irish towns, and even at places near the coast, "almost beside the living shoals." As to other kinds of salted fish, such as the dried kinds, the evidence from Galway shows that the Irish fish are cured in a coarse and careless way, and so cannot yet compete with the Scotch or English in the foreign markets. The great success which has attended the establishment of certain stations by the British Fishery Society, such as that of Pultney-town at Wick, indicates the nature of some remedial measure. When steam navigation or a railway is at hand, fresh fish at remunerating prices may be sent a long way to market; but even irrespective of these facilities, a great deal may be done as between an active and adventurous population on the one hand, and a few liberal curers on the other. According to Mr Loch, the great danger of the British Fishery Society arose from a tendency to over-building, while almost all that is essentially necessary to place the curer or fish merchant in a position for active operations, is a convenient and commodious station for his work, and a weather-tight shed for his salt and barrels. The establishment of curing stations in favourable positions in the N.W. of Ireland has been therefore recommended as likely to lead to advantageous results, though, considering the constitutional difference in the character of the people, the commissioners are cautious in anticipating any immediate sequence of those effects which have attended the labours of the British Fishery Society in Scotland. They are favourable to the granting of loans to fishermen in aid of building and repairing boats, and furnishing nets and other gear, a species of benevolence which must be exercised with caution. Where the distress to be relieved arises from disasters at sea, unavoidable sickness, or temporary depression in trade, its relief may be safe, but such relief must not be suffered to draw additional hands into an occupation already sufficiently

Irish sea-fisheries.

supplied. In Scotland the grants for the repair of boats and aid to fishermen have been recently withdrawn, and the money added to the sums applied to the erection of piers and the improvement of harbours. In the last-named country the curing of fish is kept as a distinct trade from that of their capture, and the necessary advances of money are made to the boatmen by the curers. The Irish commissioners, probably feeling that more was expected from them than was reasonable, have thought it their duty to declare that the result of their most anxious inquiries has been a full persuasion that no means can be proposed for obtaining, by any summary process, so desirable an event as a sudden amelioration of the Irish fisheries. "The progress of a gradual improvement may indeed be assisted and hastened by certain measures, in which the government might beneficially co-operate; but a real and permanent prosperity can only be effected by the hearty endeavours of individuals and bodies locally interested, who, from good motives or trading enterprise, may seize favourable opportunities and apply means for the purpose."

It is obvious from the form of Ireland, her deeply indented creeks and spacious bays, that that great island presents an extraordinary range of coast compared with her actual area. She is therefore surrounded by a proportionally greater and more easily accessible supply of food. The denseness, notwithstanding the recent exodus, of her population, her improved commercial facilities, increasing command of markets, and stronger infusion of the Saxon blood, would seem to hold out a fair prospect of a remunerating trade. From what is known of her natural resources, it might have been imagined that Ireland would not only furnish an ample supply of fish for home consumption, but such a superabundance as would meet and satisfy a foreign demand. But the actual fact is the reverse of this—the quantity captured around her coasts falling far short of the requirements even of her own ill-fed inhabitants. "And during the height of the late terrible famine, when it might have been thought that a people curtailed in the fruits of the land would have availed themselves of those afforded by the sea, one of those anomalous contrasts so frequently occurring in the history of Ireland was presented,—the implements for capture were powerless in the hands of the poor,—the food itself rotted in masses for want of the means to preserve it, and the country obtained its chief supply of an article, the use of which is enjoined by the prevalent creed, from the industry of another people." Hore's *Inquiry*, p. 123. It certainly became the duty of our rulers (and one which was munificently responded to) to enlarge the means of life to a nation undoubtedly afflicted, from whatever cause, by "a desolation wider than any recorded in history, or shadowed forth by tradition." *Report of Committee on Poor Laws* (Ireland). 1849, p. 301.

It was observed that no branch of the industrial resources of Ireland suffered more severely, in the first instance, from the deep distress of the years 1846–7, than the fisheries,—both those of inland waters and the deep sea. It is recorded by the Irish commissioners of public works, that in the autumn of 1846, when the impending famine was certain in all its horrors, and when deaths from starvation had already occurred, supplies of fish, the most abundant which had been known for years, existed on many parts of the coast, and that on portions of the southern and western shores, large quantities of fish were allowed to rot, or were even scattered as "dung upon the earth." This extraordinary state of things is supposed to have resulted partly from a prejudice against the use of fish as a dietary, without potatoes, partly from the utter prostration and distress which the want of food produced (and which compelled the coast population to dispose of their boats, tackle, and all other gear and implements of future earnings, that they might maintain existence), but mainly from the fact, that the fisheries of Ireland, however valuable and important, are not settled or assured on the solid basis of an established trade, nor followed or maintained as a real commercial undertaking for the profit which they would directly yield. Whilst the sea-fisheries were thus injuriously affected by the withdrawal of boats and tackle, left to rot upon the shore, or in pawn-offices, or by the fishermen themselves resorting to the more sure and immediate means presented by the public works, and to soup-kitchens for the bare support of life,—the inland fisheries were materially injured by the increased infringement of the laws passed for their protection and improvement. The poor and suffering people thus appear to have left undone the fishing work to which they ought to have attended, and to have attended to that with which they had no right to intermeddle. "The fact of great numbers of persons dying from want of food (or such profitable employment as would enable them to buy it) along the shores of a sea abounding in fish, and which was calculated to afford remunerative employment in its production, has established beyond all controversy the necessity for permanently developing and relying upon the fisheries in this country as a source of industry and trade, and consequently of food." Sixteenth *Annual Report* of the Commissioners of Public Works.

This total derangement in the social condition of the great mass of the coast population, occasioned by the famine of 1846, rendered it impossible, through the existing registry of boats, to arrive at any calculation even approximating to accuracy regarding the number of men or vessels engaged in the fisheries. Boats lay upon the beaches unemployed and abandoned, not immediately ceasing to exist, but by degrees mouldering to decay, while ownership in many cases was denied, lest this test being applied, might debar the parties concerned from receiving gratuitous relief. The following abstract exhibits the number of vessels, men, and boys upon the register in 1845 before the famine, and the number afterwards ascertained approximately for 1849:—

	Before the famine. 1845.	Since the famine. 1849.	Decrease.
Number of vessels and boats of all classes	19,883	15,247	4,636
Number of men and boys employed	93,073	68,380	24,693

In relation to the preceding, the inspecting commissioners state that they have reason to fear the decrease is underrated. It has since been ascertained that it is greatly so, and that the falling off both in boats and men is much larger than above stated.

The establishment of the government curing stations at Inniscoe, Kyllebegs, Belmullet, Roundstone, Valentia, Castletown, and Baltimore, has been of as much benefit as could, under the circumstances, have been anticipated, and although the commercial winding-up of such undertakings may not exhibit a profitable pecuniary result, yet in an educational point of view, and as examples of an ameliorated system, and a higher standard, much may have been gained. The actual extent of business transacted is, in such cases, of less consequence than the production and exhibition of an improved article, and an opportunity to those who desire training to acquire a better and more thrifty mode of management.[1] Fish being an article that pays no rent,—a

[1] The experiment was tried by making a loan of L.5000 from the Reproductive Loan Society, and considering the nature of the country and its people, that seven stations were formed, buildings, smoking-houses, and others, required for the trade erected, agents, fish-curers, and rents paid, salt, tackle, and other articles imported, and numerous people employed at full wages, and a sum of L.900 returned in a season or two to the Lords of the Treasury, surely a beneficial purpose was obtained.

Several adverse circumstances attended these humane endeavours. The people at Inniscoe were so weak and depressed as to be almost

free gift as it were of nature to its captor,—it might be thought that the occupation of the fisherman would be equal to itself, and require no artificial fostering from without. Yet many nations have made powerful efforts to create or increase their fisheries, and some of them in vain. Sir Charles Morgan assumes that the solution of this seeming paradox lies in the perishable nature of the commodity, and the consequent disproportion between the cost of taking, and that of preserving and conveying it to the distant market. To transport fish in a fresh condition so rapidly enhances its price, that at a small distance from the sea it becomes an article of luxury, and its market is restricted accordingly. Only inferior kinds can be offered for sale at such prices as permit their being used extensively as articles of ordinary food, and these kinds are so low in their nutritive qualities, and so much less tempting to the palate, than what is commonly called animal food, that people who can afford to purchase butcher meat will not consume much fish. Except during occasional large supplies of fresh mackerel and herrings, the artisans of London but rarely purchase fresh fish, and the cured or salted sorts they seem almost entirely to decline. We believe, however, that the abundant supplies of fresh fish, at a diminished price, which are now, by means of railways, poured daily into the great commercial cities of the south, have increased the inclination towards that pleasant and salubrious food.

"To obtain," says Sir Charles Morgan, "an extensive sale for this article, it is for the most part necessary that it should be subjected to the processes of curing, and rendered capable of conveyance to far-distant markets. But the curing of fish, while it implies a considerable degree of art and some outlay of capital, so far decreases the estimation of the commodity in consumption, that salt fish usually finds a still less ready market than fresh, and in thriving communities it is consumed only by the poorest population, and at times when better articles of diet are scarce and inaccessible. The general use of even the best kinds is very much confined to Catholic countries, and depends rather on a dogma of religion than on a principle of political economy.

"Fish, therefore, must be an object of commerce very readily liable to over-production, and sudden fluctuations in the quantity taken greatly increase the difficulty of maintaining a proper ratio between demand and supply. The fish market is constantly varying between extreme points of glut and scarcity; and the necessary consequence must be a low average profit to those engaged in its capture.

"The fisheries, as an object of national importance, depend altogether on a demand for the salted article, and that too in some more extensive market than the immediate neighbourhood of the fisheries ordinarily affords. Before such a market is found and rendered accessible, it is to no purpose that fish abound. They exist in the sea, as good land lies in the back settlements of America. Both are susceptible of supplying the wants of man; but both are useless through their distance from a centre of distribution. Again, the most productive fishing grounds of the British Islands happen to lie principally off remote and ill-inhabited coasts, and before they can become extensively available to the native population, capital and industry must seek them out, and bring to the spot all the materials for curing and for fishing on a large scale. But in a climate tolerably genial, such a mode of investing capital would hardly be adopted, until the demands of agriculture and manufacture were tolerably satisfied.

"Accordingly, it was the Dutch who, having little land to cultivate, and being dependent almost exclusively on commerce for subsistence, were the first to render the fisheries a staple of national industry; and they are still the only nation who have very largely depended on that species of wealth for the source of their prosperity. For England, from its earliest commercial existence, capital has found ample sources of investment without embarking largely in the fisheries. Although its waters abound in fish, the trade for ages was very nearly confined to the supply of the local markets; and it was not until the time of the Stuarts that the fisheries excited public attention; when, owing to the political jealousies then commencing between England and Holland, the desire was formed of depriving the Dutch of their herring trade, and of thus crippling her warlike resources.

"In this anxiety to injure an enemy, the nation did not advert to the different situations of the two countries; but rushing at once into a cumbrous and expensive scheme for becoming *impromptu* fishermen, they entered blindfold upon a series of experiments, from which even now they are not totally disengaged. The eagerness of the nation to jump to the desired conclusion would not brook the naturally slow development of the trade, but strove by monopolies and privileges, by bounties, &c., to force it into a precocious maturity. The result was (as might have been foreseen) reiterated failure; and it was not till the war of the French revolution had utterly annihilated the Dutch commerce, that a real opening was made for the profitable investment of British capital in this branch of industry. To these causes of failure, which circumscribed the growth of the British fisheries, others peculiar to Ireland may be added. Besides the necessity imposed on the latter country of following in the career of the former, two circumstances may have been active in drawing the attention of Ireland to the resources of its waters. 1st. The neglected state of the manufactures, and consequent want of employment; and, 2ndly, the periodical recurrence of local famines. The latter, more especially, could not fail to excite the attention of the public by the dreary contrast it presented between starvation on shore, and an abundant supply of food existing in the neighbouring sea; a supply which wanted only to be taken to become available to the wretched peasantry. Accordingly, the money raised by charitable subscriptions has more than once been spent in equipping the coast population to become fishers; and legislative efforts have been made to attain the same end, in a more permanent way."

The following were the instructions issued to the government agent at each of the established curing stations already named.[1] 1. To afford employment and fair remuneration to the fishermen, by purchasing the fish which they may take, thus ensuring to them, as far as possible, a steady daily market. 2. By a regular market to promote an increased capture of fish, and thus provide an additional quantity of cheap food for the country. 3. To render that food valuable and available to the fullest extent, by adopting such modes of cure as may be required

incapable of exertion; and as soon as the potato planting commenced, the fishermen all abandoned the fishing at the very season when their operations would have been followed by the greatest success.

An unfortunate circumstance happened at Belmullet after the opening of that station, when the fishermen had been for some time delivering large quantities of fish. A body of them residing at a place called Tip plundered a vessel laden with flour,—they were arrested in the act by the coast guards, and thirteen curraghs, with their crews of four men each, were brought into Belmullet. The men were confined in prison for several months, and the curraghs, of course, detained, "which was necessarily a great impediment to the success of the station."!

[1] That a set of cooper's tools could not be found in Ireland suitable to making the vessels required in fish-curing is an evidence of the backward state in which the fisheries remained, considered commercially. A few skilled coopers, with the necessary implements, have been sent from Scotland.

Irish sea-fisheries.

to preserve it; and such also as will suit the demands for its use either near the coasts, or in markets of the interior.

There was reason to expect, according to the commissioners' report for 1845, that the construction of railways in Ireland would impart new life and vigour to the fisheries, especially those on the western coast, where, although the choicest description of fish are found in great abundance, yet the fishermen are indifferent if not opposed, to the adoption of improved modes of capture, chiefly from want of sufficient and remunerative markets for their disposal. "From some parts of the south of Ireland an export to the English markets of superior kinds of 'flat fish,' packed in ice, has already commenced; and from the whole of the north, east, south, and south-west coast, very large quantities of salmon are shipped, having previously afforded extensive employment to great numbers of persons engaged in their capture, preparation, carriage, procuring of ice, and packing, &c. The progress of improvement in the fisheries of Ireland is doubtless materially checked by want of small piers and harbours on the coast; and we are of opinion that every reasonable encouragement and assistance should continue to be afforded, with a view to remedy this palpable evil, in conjunction with an improved organisation of system in the collection of local funds applicable to the same purpose."

Some have advocated the supply of suitable boats, rigging, &c., by means of grants or loans, through the instrumentality of government, seeing that for a great extent round the north-west coast of Ireland, very few first-class fishing-boats, suitable for deep-sea fishing, are to be found. In one district (Report for 1845) containing 52 miles of coast, there was only one such boat registered, while, in another of 174 miles of extent, there was not a single sea-going boat. The most effectual remedies, and those now advocated, and successfully practised in Scotland, are the erection of additional and more commodious piers and harbours, for the encouragement and protection of men and boats, the opening of markets for the disposal of produce, and an increase in the means of communication.

In the commissioners' twentieth annual report (of date August 1852), we are informed that the opening of the railway from Dublin to Galway has given great stimulus to the fresh fish market there, and large supplies of sea-fish and lobsters have been sent to Dublin and the English markets by that route. They look forward to much greater results so soon as certain local prejudices regarding trawling, and the improved modes of capture, gradually yield to the influence of a regular daily market, and remunerating prices. The branch from the Dublin and Cork railway to Kilkenny, and the completion of the line between Waterford and Limerick, Waterford and Kilkenny, with the increasing steam navigation from these ports, have operated in giving a new and increased value to the fisheries of the south and west coasts. It is regretted that the county of Sligo, and the greater portion of Mayo and Donegal, have no immediate prospect of such advantages, although they possess some of the finest fishing banks off their coasts, but require railway communication as the primary means of developing their industrial resources, by placing them more upon an equality with the rest of the kingdom. The gradual junction and completion of the northern Irish railways, and the daily steam communication from the ports to England and Scotland, have already afforded to those quarters the advantages referred to.

The deep-sea fishing of Ireland is carried on chiefly by means of long lines called spilliards, better known as spillets on the western coast. The species taken by that mode are cod, haddock, ling, hake, conger, and dog-fish. Very large haddocks, said to weigh from 15 pounds and upwards, are caught off Clew Bay, on the Innishay banks, but they are in bad condition by the time they reach the markets of Newport and Westport. The ling and cod are also very fine. The spilliard line has generally a length of 210 or 220 fathoms, with hooks fastened to it by snowding lines of nearly two fathoms in length, at a fathom's distance between each snowding. There are thus 200 baited hooks on each spilliard, one spilliard is a man's share, and every boat carries five spilliards, or 1000 hooks. These, after being baited, are arranged in a basket in circular rows, and the line is set by the boat being rowed over the fishing ground, the hooks descending over the side, and dropping into the sea without entanglement, as the line veers out. If the fish are biting freely, the first hooks are lifted immediately after the last are laid, but it is the more frequent practice to let them lie from six to twelve hours in the water. The bait is usually small pieces of fish of about an inch square, and half an inch in thickness. The conger eel is the most successful kind in use upon the western coasts. The mussel is the best bait for haddocks, lug-worms (much in favour with flat-fish), and the inhabitant of the scollop shell, are also had recourse to. In many places there is a scarcity of bait, and consequently a difficulty in obtaining it,—an inconvenience also experienced on the Scottish coasts. These spilliard lines are partially supported by buoys, placed at long intervals, made of dog skins filled with air, and called watchmen by the natives. Mr Brabazon informs us, as an example of what may be achieved in this way, that in the early part of 1847 three boats left Port Rush, and went round to the western coast to try the long line fishing. They returned, after an absence of seven weeks, with a cargo of thirty-six long hundred (of six score) of ling (that is 3600 fish), which they sold for 8d. a piece, independent of a supply of cod, hake, conger, and six barrels of oil to each boat, taken from the cleanings. These people green-salt their own fish. Four men split and gut them, two men wash them in a trough full of pickle, and as soon as they are clean, two men carry them up the beach, and lay them out on rocky or stony places, free from sand. They are afterwards packed up in large square piles upon the beach, being covered with a tarpauling in wet weather, and also at night to keep off the dew as well as rain. The Rush fishermen have eighteen score of hooks to each man's share of line, and they have a buoy at the end of every share. The lines are shot in succession from the boat, according to lots previously drawn from a hat, if they have one. They are shot across the tide, which keeps them clear, for when dropped with the tide the lines are apt to bunch up, and so get foul. They dare not shoot them in stormy weather, as the friction on the buoy line produced by the rolling at the surface would cut them across, and the rubbing against the bottom is also injurious. This fishing is usually practised over rough and rocky ground, or in water too deep for trawling. It occasions great fatigue to the men, who have to go to and from the scene of operations, in small row-boats, every day. To remedy this inconvenience various plans have been suggested, especially the establishment of fishing companies, with large vessels, well supplied, and capable of standing out at sea till a full cargo is obtained.

"A company," says Mr Brabazon, "undertaking the Irish fisheries for profit, at the same time that they gave remunerative wages, and afforded the fishermen of the coast a certain medium price for their fish, whether there was a glut of fish in the market or a scarcity, would be the best way of improving the condition of the people along the west coast, and certainly lessen the effects of famine with which they are so often visited, by the failure of their crops. The company should establish stations along the coast; say they began with three, one at Kyllebegs, one at Newport Pratt, and one at the Shannon mouth, it would be found that when vessels could procure a cargo of cured fish without delay at

Irish sea-fisheries.

the company's stores, it would create an extensive trade with the west of Ireland in fish, corn, coals, and salt. Each station should have a store, curing house, and ice-house attached to it. From the store at Ballyshannon, I would send the fresh fish packed in ice, and also cured fish by water carriage through the Enniskillen lakes, and by the Ulster Canal on to Belfast, supplying all the intermediate towns and interior of the country, giving a great deal of employment to the owners of carrier boats at so much per ton freight, and have it sold by agents at different localities through the interior, who would be paid by a percentage on the sales. Upon the same principle, the fish from the station at the Shannon mouth could be sent up the Shannon per steamer, and on to Dublin, taking advantage of the cheap water carriage afforded by the canal. The company could either have their own boats for carriage, or give that employment to the carrier boats already established on these lines.

"The chief expense to the company would be a fleet of three or more large wherries or schooners of about 150 tons burthen at each station, and a tender of 50 tons. They could attend all the fisheries, herrings, long-lines, sun-fishing, and trawling, at their different seasons. I would prefer wherries to cutters, as they have not the great weight of masts that cutters have, the weight being divided, which would make them work much easier in the heavy rolling seas of the Atlantic, nor have they the great weight of boom of a cutter, which takes up a good deal of room, and requires many hands to work in stormy weather; they are also much easier made snug in a short time in a heavy burst of bad weather, or white squalls, so common on the west coast of Ireland; also from their having a long line of low canvas, when close reefed they can beat into shore in any gale, when a cutter, from her narrow taut trisail, would make a bad hand of it. One fact in favour of the wherry rig is, that there is a wherry in Howth (the Bull) of 40 tons burthen, which on several occasions carried the mail-bags across to Holyhead in the days of the sailing packets, which were fine cutters of 70 tons, but which could not put to sea in such weather. They have a great advantage as trawlers in the act of jibing, which they often go through while shooting their trawl. The expense of each of these vessels would be about L.1000, fully found with trawling gear, long lines and hooks, herring nets, harpoons and lines, and two good whale boats for each vessel, so that they could attend each fishery in its season. These vessels should be manned by a crew consisting of a skipper, mate, or store-keeper, three men and a boy, who should have charge of the vessel and never leave her. I would take crews of the coast fishermen for the whale boats, that is, two crews for each boat out to the fishing ground, and maintain them on board until the vessel had her cargo of fish caught, then return to the station, discharge her cargo into the store, take in fresh provisions and water, and go to sea again. These vessels could run out to the fishing ground with the crews of the whale boats on board, a crew could then man each of the boats, and shoot their lines from them; while the two spare crews on board could also shoot their lines over the vessel's side, when the crews of the whale boats lifted their lines and came on board to take off the fish, and rebait the first lines shot, the spare crews could man the boats and lift the lines that had been shot from the vessel. Thus each boat's crew could make three or four shots of as many sets of spilliard lines as belonged to each crew in the day, as they would not be fatigued with rowing or sailing fifteen or twenty miles to the fishing ground, but leave the vessel's side fresh after their meals. During the time they were fishing, the vessel could beat up to windward and shoot her trawl, which would keep her under such easy way that the boats could make her at any time. If there was a great take of fish, and fine weather, these vessels could tow out four or five of the shore boats with their crews also, sell them what provisions they might require, and buy their fish at so much per cwt., and give it a partial salting on board,—what the North Sea fishermen term green-salting, that is, in case of their being delayed at sea. Then on Saturday evening run into the station, land their cargo, replenish the ship's stores, and run out again to their fishing ground on Monday morning. It is only by fishing with large vessels of this class that the great difficulties presented by the storms of the Atlantic, and the mountain tempests of the Irish coast, can be successfully contended with."[1]

This scheme of a commercial fishing company for the advantageous development, in favour of all concerned, of the marine resources of Ireland, is advocated and explained in a more recent work.[2] Galway is recommended for the headquarters of the company, as combining all the advantages requisite for success. It is situate at the head of a magnificent fishing bay, thirty miles long and seven miles broad, in which almost every sort of fishing may be carried on throughout the year in its respective season. It is likewise in the centre of a district of coast abounding with fish and bait of every kind, with good harbours, and a fishing population of 7297 men, 497 boys, with 1818 boats, while there are extensive salmon and white trout rivers, from which these fish may be obtained on advantageous terms. There is a considerable local demand for both fresh and cured fish, especially for the somewhat coarser kind, which do not so surely pay the expense of distant carriage; there are capacious docks, with storeage and curing houses to any extent desired, at a moderate rent, with cheap markets for provisions, and a railway station within six hours of Dublin, eighteen of Birmingham, and twenty of London. The craft recommended are, vessels from seventy-five to eighty tons, some of them to be fitted with wells for keeping fish, lobsters, and bait alive; also a smaller class of vessels of from twenty-five to thirty tons for the drift-net fishing, and a class of row-boats, from thirty to thirty-five feet long for the bay herring and mackerel fishing, and for working the seine nets. Lastly, a fore-and-aft schooner well-boat, with an auxiliary screw propeller, to be employed in carrying fish from the vessels on the banks, or the stock purchased at the stations along the coast.[3] She would prove a valuable auxiliary in towing the vessels or drift-net boats to the fishing grounds in light weather, and in the capture of sun-fish, which generally show themselves during calms. Commander Symonds concludes his pamphlet by the following *résumé*, p. 55.

1. That the waters of the west coast of Ireland abound with cod, turbot, soles, lobsters, and other fish of the finest quality. 2. That the want of success which has heretofore attended any development of these fisheries, has arisen from

[1] *The Deep Sea and Coast Fisheries of Ireland, with suggestions for the working of a Fishing Company.* By Wallop Brabazon, Esq. Dublin: 1848.

[2] *Observations on the Fisheries of the West Coast of Ireland, having reference more particularly to the operations of the London and West of Ireland Fishing Company.* By Thomas Edward Symonds, Commander, R.N. London: 1855.

[3] "In the construction of the above vessels it will be necessary to effect such a combination of form and rig as will render their adaptation to different modes of fishing both facile and expeditious. They should unite considerable speed with average stowage and good accommodation for the men, and have the least possible amount of gear and rigging, so as to keep down wear and tear. These advantages may be readily combined in fore-and-aft schooners, similar to those the Americans use in the South Sea seal-fishery, which are splendid sea boats; this rig is admirably adapted to the west coast of Ireland, which, in common with all mountainous coasts, is subject to sudden and heavy squalls when the wind is off shore, the sails and spars being lighter and more easily handled than those of a cutter of half the tonnage."—Symonds, p. 12.

Irish sea-fisheries.

the inadequacy of the capital and means employed. 3. That there is in London alone a demand for fish exceeding in quantity anything which could be imagined by those who have no practical experience in the matter. 4. That the regular supply of fish to the principal markets in better condition than has hitherto been accomplished, and at a lower price, must necessarily create a more extended demand. 5. That the application of steam in the manner suggested, and which forms one of the main features of the London and West of Ireland Fishery Company, is an element of the highest importance in an undertaking of this kind, and, combined with the favourable arrangements which will be made with railway companies, will save the loss of time which has heretofore occurred, and consequently the enormous loss occasioned between the quantity of fish caught, and the quantity capable of being delivered at the markets in good condition. 6. That the application of a process for converting the coarse fish, and the refuse at the different curing stations, into manure or fish guano, will itself form a valuable source of revenue, by turning to profitable account that which is now thrown away. 7. That the application of capital on the west coast of Ireland, in a national point of view, must be attended with most beneficial effect on the national industry of the country, and the conversion of the waste fish into manure must also be hailed as a boon to the agricultural interests.

The fishermen of the western shores of Ireland, however uninstructed in many things, are said to understand their own vocation well, at least so far as hook-fishing is concerned. What they chiefly want are more regular markets to induce and reward continuous labour. Their boats are, however, too often "ill-found," being very deficient in sails, rigging, and fishing gear. Mr Brabazon mentions, that scarcely one crew in every ten in Clew Bay have fishing tackle, but believes if they were supplied with the requisite materials at a moderate price, they would bring ashore great store of fish. The distress among the fishermen of the east coast, he thinks, is chiefly caused by the spawn upon the fishing banks being destroyed by trawlers, while on the west coast their poverty arises from the want of markets or demand for fish. "The fishermen often see the west coast crammed with fine fish, when they could take tons of them at a haul, or shot, with a deep seine or drift-net, but when caught they would be useless, as they could neither salt nor sell them. I have been told by an inspecting officer of the coast guard, that he has several times seen herrings on the coast of Donegal sold for 10d. per 1000, which would make two barrels of herrings, worth in Dublin L.2, 10s. Different persons, to whom I have talked about the fisheries on the west coast, expressed a doubt that bait could be found in sufficient quantity to carry on an extensive fishery. I have never felt a doubt upon this point, as any fisherman will tell you, that wherever there is a *fish* there is a *bait*, as the fish are the bait in case a less expensive one cannot be obtained; but there is always a mixture of inferior fish fit for bait in the same shoal with prime fish."

The boats which prosecute the herring-fishery off the western coasts of Ireland are very inadequately provided, especially as regards the smallness of their train of nets. Each train is generally composed of from six to ten parts called slings, and a sling is about 25 fathoms in length. The Galway and west coast nets are 6 score of meshes (about 9 feet) deep, while our Scotch nets are at least 15 score, or 22 feet deep. Thus the Irish nets are so narrow, that large shoals of fish can easily pass beneath them, even in a moderate depth of water, where a Scotch net would stop the passage and *mesh* the fish. The Irish nets are generally attached to what is called the back rope, and the buoys have seldom more line attached to them than suffices to secure them to that rope. Thus the upper edge or line of the net is necessarily always at or close upon the surface, as there are no means of lowering it, however deep below the fish may be. But the St Ives men and our Scotch fishers, besides having deeper nets, can let them sink by lengthening the buoy ropes, which are fastened at intervals to the back rope, or that called the spring-back, which runs along the whole length of the train, and is strong and thick from its fastening at the boat to about the centre of the train, and lighter from that centre to the farther end. The buoy ropes are several fathoms in length, so that the nets can be depressed from, or raised towards the surface, according as the shoal of fish is high or low.

That the herring-fishery might be made of great value to Ireland is evident from the fact, that her people frequently import above 100,000 barrels of that fish from Scotland. It is alleged that a great falling off has taken place in the herring-fishery of Ireland for ten or twelve years (prior to 1850). Formerly abundant supplies were frequently obtained upon the west and south coasts, purchasers from Scotland and elsewhere attended, and a trade existed upon a large scale, of great importance to the country. It is not improbable that the fish are still upon the coast, although they may not now embay in the same places as formerly. Changes of this kind have been noted as occurring off the western isles of Scotland, especially about St Roag and other stations on the outer shores of the Long Island, in the bays of which herrings, now rare, once abounded. But there is no doubt, that a fair fishing harvest is still reaped from year to year, by others than the natives, off several portions of the Irish coast. A herring-fishery is uniformly prosecuted off the east coast of Ireland, whither a fleet of between 200 and 300 vessels, chiefly Cornish, annually repairs, and for several weeks is continuously and profitably occupied in the capture of these prized fish, for the supply of the Dublin and Liverpool markets. The commissioners (in their Report for 1851) remark, that the only really important herring-fishery which came under their observation in a concentrated form, was most abundant. "Our *Cornish neighbours*, this year, have visited Howth and Kingstown in increased numbers, and with unusual success. They have had an excellent season, a fair take, and good prices." These results seem all that fishermen can reasonably look for here below.

Many of these fish, after coming into the hands of Scotch or English curers, are shipped to Dublin and other Irish ports, and sold there at from 26s. to 30s. per barrel. It is clear that if cured upon the spot, they might be disposed of at an equal profit to the producer, and at a great reduction to the consumer.

In regard to the natural abundance of Irish fish, we may here quote from a report made in December 1853, by Mr Howard, a gentleman who has been fishing the North Sea and coast of Norway in welled vessels during these last thirty years, for the supply of the London markets with live fish and lobsters.

"Having proceeded all round the southern coast from Cork to Breahaven, and from my own inspection, and from what I heard from persons of all classes, I have no hesitation in saying, both as regards quantity and quality, the banks off the coast and the Irish shores are richer in fish of all descriptions than those of any country I have ever seen. I spent a day and night at Kinsale—the only place in the south of Ireland where the fishings are carried on to any extent. There are, I think, about forty hookers, the largest only thirty tons. These being only half-decked could not with safety, I conceive, live in a heavy sea; and as not one of them has a well, the fish are killed as soon as captured, and daily brought on shore; and I am further convinced from the inspection of all the fishing gear, that not half the quantity are taken that might be, if the hookers were equipped in an efficient manner. I saw the fish on the morning of the 29th, when landing from the vessels; the cod, haddock, and ling, were very prime,—the haddock, I

Irish sea-fisheries.

am convinced, the finest in the world. I proceeded along the coast to Crookhaven, Bantry, and Breahaven; at every place we found the fact corroborated as to the abundance of fish; but, except a few small boats in Glandore, Baltimore, and Breahaven, there were none to be heard of, as the fishing has nearly ceased from 1847, in consequence of famine, emigration, and no market for the fish, if taken. On returning from Breahaven to Bantry, we came by boat, and literally rowed across that fine bay through a *bank of herrings;* and I feel confident that with nets, such as those used in Scotland, the Isle of Man, or on the Cornish coast, 40,000 barrels might have been taken that night; in fact, the whole coast was swarming with them, and if properly fished, would rival Scotland in her annual take."

The following relates to the produce of the Galway coast. "The Claddagh fishermen have been blessed by Providence with an abundant harvest, in their line, this week. On Wednesday night the boats were actually laden to repletion with herrings. They had scarcely reached the roadstead, going out to lay their nets, when the shoal met them, swimming against the sides of the boats, and under the clear and beautiful moonlight, illuminating the bright waters as though it was a sea of silver on which they floated. Next morning the cargoes were sold, but not at a price equivalent to their value: 17s. per 1000 was the highest figure, and from that down to 14s.

"The herrings were remarkably fine, some of them being nearly of the size of bream or mullet. The quantity of hake, cod, and other fish taken, was unusually large; and if proper sources for the sale of it were available, the fishermen would be well rewarded for the risk and labour they undergo. Very fine hake or cod fish hawked about would be bought for a penny or twopence a-piece."—*Saunder's News Letter*, 6th November 1854.

The western coast of Ireland has, moreover, like Yarmouth, and our own Firth of Forth, the advantage of a regular *winter herring fishery,* which, if assiduously prosecuted, and with the aid of a screw-steamer, in addition to the railways, might be made very profitable, during a season which admits of a lengthened journey, with little diminution of freshness. The fish are of great size, and when in full season fourteen of them are said to weigh a stone. They make their appearance in December, and generally remain for about ten weeks. They may be often purchased, in any quantity, at from 10s. to 15s. per long thousand, while in a great city market they would probably realize in retail from 6s. to 8s. a hundred.

The *cod* and *ling* fishery of Ireland may be prosecuted during ten months of the year, being divisible into the early or in-shore fishing, and the late or distant fishing. From the month of November until the middle of March the cod fish are in prime condition. In May 1853, Captain May of the coast guard at Clifden, county of Mayo, stated that a person of the name of Butler of that place was absent for three days in a small hooker of five tons, with four men, and returned with forty dozen of fine ling. In December 1854, a row-boat, with eight men belonging to Cleggan, in Mayo, took fifty dozen in nine days, besides a quantity of other fish. It has been inferred that if these quantities are not unfrequently taken in a desultory manner by ill-equipped vessels, a much larger capture would reward those who pursued the fishing in a more systematic and efficient manner.

There are great quantities of *turbot* on the west coast of Ireland. They often cut up these fine fish *for bait* for their long lines. Boys will wade into the water with small spillet lines, and with these they will take from fifteen to twenty *chicken*, or young turbot, at a cast. *Haddocks* abound, and if kept alive in welled boats, so as to reach the London market undeteriorated, would fetch a high price. In the west, according to Commander Symonds, they are of great size, and when fresh and in fine order, are even superior to the celebrated Dublin Bay haddocks. The *soles* are said to be equal to those of Torbay, and may be taken in large quantities at Dingle, and many other places, as well as in the deep sea. *Hake* fishing begins in June and ends in November in Galway Bay, and during that time from 500 to 1000 are usually taken in a haul of five or six hours in the trawl-net. *Dory, brill, holibut,* are abundant. Large *mackerel* are driven into Arran (thirty miles off) by the sun-fish in spring, but a smaller kind swarm in Galway Bay in June. *Sprat* fishing is followed chiefly for the sake of the oil, and the fish themselves are bought at a cheap rate by the poor people after the oil has been expressed. The quantity is almost unlimited. From August to Christmas last (1854), they may be said to have existed in a solid mass both within and outside the Galway docks, and on several nights they rose to the surface in such numbers that the people took them up in hampers, which they filled to the brim at a single dip. A person totally unacquainted with trade was induced to expend L.250 in the purchase of sprats, from which *four thousand gallons* of oil were made, worth about two shillings per gallon, or L.400. "After expressing the oil," says Symonds, "nearly 300 tons were sold for food, the proceeds of which covered all expenses." The selling price, in the fresh state, is from six to ten shillings per ton. *Lobsters* are very plentiful along the west and north-west coasts of Ireland. Large welled boats are sent from London and other English ports, and purchase them for from four to six shillings a dozen. *Ten thousand* per week may be obtained at that rate from many stations, and the average wholesale price at Billingsgate is one shilling each, or L.50 per thousand. The returns of the Midland and Great Western Railway of Ireland show that 101 tons 6 cwt. of lobsters were carried from Galway by that line, in addition to those transported by sea to London.

Another occupation, formerly much practised in Scotland, but now almost peculiar to Ireland, is that of sun-fishing. The sun-fish is the *Squalus maximus*, or basking shark. If the weather is bright and warm towards the end of April these gigantic creatures are sure to show themselves, and are visible at a great distance to a practised eye, in consequence of the dorsal fin projecting several feet out of the water, while its owner lies upon the surface basking in the sun. At this period of unwary indolence they are easily approached by a boat, in the bow of which a strong-armed man stands steady with harpoon in hand. The barbed weapon is attached to a line of 200 fathoms coiled up in circles on the fore-sheets, and another man is near with a hatchet ready to cut the line should it chance to get entangled with anything in running out. When the fish is first struck he makes a tremendous rush of a hundred fathoms, or it may be more, descending, as the fishermen allege, to the bottom, where he rubs and rolls himself to get quit of the harpoon. He is generally allowed to take his own way for about an hour before his captors begin to haul upon the line. In doing so they carefully coil up the slack in readiness for another run, just as the salmon-fisher keeps his reel in order, with this difference, that the worst mishap will only graze the skin of the angler's finger, whereas in the case of the *Squalus* a man may be drowned, or lose an arm or leg, by the rapid motion of the rope. Sometimes, when the fish is powerful, as well as sulky, eight or nine hours will elapse before he comes to the surface, having this great advantage over a whale, that he can breathe under water. He is struck again as soon as an opportunity offers, with one or more harpoons, and is finally hauled to the vessel, alongside of which they stretch him fore and aft with a jowl rope around his head, and the bite of a hawser round his tail. His own bite is not to be trusted, and to destroy the enormous power of his caudal extremity, two deep cuts are inflicted with a hatchet on each side the tail. They then cut flesh holes in his body on both sides, through which they reeve strong

Irish sea-fisheries.

Scotch sea-fisheries.

ropes, and by hauling these taut on the side of the fish next the vessel, and slacking away on the opposite one, they contrive to cant him over on his back. They then split him down in front, take out his liver, and allow his huge carcase to go adrift. This fish, which is of great thickness, sometimes measures thirty-six feet in length. There is no blubber between the skin and the flesh as among whales, but the oil from the liver is as fine as spermaceti, and a single fish will yield a couple of tons worth L.50. They are frequent on what is called Sun-fish Bank, about 100 miles west of Clew Bay. The fishermen there reckon it a day's sail out of sight of land. They are also met with in large numbers off Tory Island, and along the north-west coast of Donegal, where the Skerries men have sometimes found them so abundant that they dared not venture out to lift their cod lines in case of accidents to their boats. Though of a sluggish nature they must be harpooned with caution, as a blow of their tails would stave a boat to pieces, or throw the wounded men into the water. The chief defect in the Irish mode of attacking the sun-fish is, that the fishermen are unacquainted with the use of the lance, a deep thrust from which, instead of a second harpoon, when the creature rises, would accelerate its final capture.

We shall now consider the important subject of the sea-fisheries of Scotland. Of these the most valuable is that of herrings. The Caithness herring-fishery is, for the time it continues, the most abundant in Britain, and Wick may be regarded as its most productive centre. Like the salmon-fishing, that for herrings is more or less a lottery. The average of the Wick fishing may be stated at about 100 crans[1] per boat, though some boats may land in all from 300 to 400 crans, while many may have far less than even the first named number. In addition to the improvement in the modes both of capture and cure, three more extrinsic things have tended greatly to the advantage of the fisheries in recent times. 1st (and this chiefly as relates to salmon), the invention of the use of ice; 2d, the introduction of steam-navigation; 3d, the formation of railways. In illustration of the vast advantage of the last, it may be mentioned that between *four and five thousand tons* of fresh herrings are now sometimes sent in a single season of a few weeks from the town of Dunbar alone, into the interior of the country. What a vast benefit to the great commercial and other cities of the south to have so cheap a supply of such salubrious food![2]

We shall not here enter into the natural history of the herring further than to say, that all that is stated by Pennant and others since his time, regarding the migrations of that fish from the northern regions, and its breaking up in vast bodies on both sides of Great Britain and Ireland, is without the slightest foundation in fact. The herring is a native fish which breeds along our shores, and never altogether leaves them, although it becomes invisible for a time, especially after the spawning period, by sinking, for security, into the deeper sea. The truth is, that at one station or other we may be said to carry on the herring-fishing all the year round. It commences in May off the eastern side of the Lewis or Long Island, and continues into mid-summer. It then spreads along both the western and eastern shores of Scotland, attaining its maximum off the Caithness coast in August. It continues in Loch Fyne and other western sea-lochs almost into the winter season. It commences in autumn off the Yarmouth district, and continues during a portion of the winter. It recommences in December in the Firth of Forth (unexhausted by the summer slaughter), and is carried on as a winter fishery. Finally, it prevails at Ballintrae, and other places off the Ayrshire coast, in spring, by which time, however, the fish are spawning, and in bad condition. We have then only a few blank weeks from the end of March to the middle of May, when herrings begin to show themselves again, as we have said, off the Lewis, at first in rather poor condition, but improving rapidly there and elsewhere as the season advances. The young are found, and too often captured, in our firths and bays of the size of sprats, a sufficient proof, had we no other, that the notion of the parent fish retiring to breed among the arctic regions is a fable.

There is no article of diet more palatable and salubrious than fresh herrings in first-rate condition. In their natural state these fish may be divided into three classes, viz., maties, full fish, and spent fish. Maties are those in which the roes and milts are distinctly but not largely developed, and this is the state in which they are in the highest order as food. Although they do not then exhibit so bulky an appearance as that of the full fish, they are in reality much fatter, for the bulk of the latter is deceptively produced by the great enlargement of the roe and milt; and this does not take place without a corresponding diminution of the body of the fish. The full fish, however, are those which are most sought after in a mercantile point of view, especially for the Irish market, because of their larger size. They are also much more abundant than the others, or at least are captured in much greater quantities, as they are then congregated in larger shoals, and also, being nearer their spawning time, make closer approaches to the shore. The great north-eastern herring-fishery of Scotland is mostly made up of full fish. It commences about the middle of July, and by the beginning of August is often general from the Tyne to Shetland. The earlier Dutch fishery contains more maties, and is carried on at a greater distance from the coast. It is of importance to encourage an early fishing among ourselves, for the sake of somewhat cooler weather, which admits of more careful and deliberate salting. August, which is, however, the chief herring month, is not seldom sultry. We shall now describe first the mode of capture, and then that of cure.

Our principal herring-fishery has, almost from time immemorial, been carried on by *drift-nets*. There is no *close time* as regards these fish, nor any legal regulations, further than that the act 48th Geo. III., cap. 110, sec. 12, declares that the meshes of these nets must not be less than one inch from knot to knot, while a more recent act (14th and 15th Vict., cap. 26, sect. 6) makes the use of the *trawl-net* in the capture of herrings illegal.

A train of herring drift-nets consists of several lengths

---

1 A cran contains 45 gallons of ungutted herrings. It is the measure by which the captors deliver their fish to the curers, or other purchasers. A barrel contains 37½ gallons of gutted herrings, and is the measure in which the salted fish are sent to market. It ought to be capable of containing 32 gallons English wine measure.

2 The number of boats fishing from, or visiting Dunbar (though belonging to other stations) in 1853, was about 350. The quantity of herrings landed at Dunbar in 1853 was 43,000 crans. The value of herrings landed at Dunbar that season was L.34,500. The value of boats and gear employed was L.43,000.

"The above," observes Mr Sutherland, the fishery officer at Eyemouth, from whom we have the information, "are for both harbours (of Dunbar), and but for the existence of Victoria Harbour (that so largely aided by the board of fisheries), probably not more than one-third of the business could be carried on satisfactorily, particularly now that there is such exertion used to get fish put quickly into packages for despatch to market, every available space on the quays and about the harbours being taken up in this way."—MS., 29th Sept. 1854.

It is evident that the combination of a railway station, with increased harbour accommodation, has rendered Dunbar a highly eligible point for the inland transit of fresh herrings. Mr Sutherland adds that the price is generally higher there than at any other station on the east coast, and that this is an additional inducement for fishermen to frequent the port. We may here note that Dunbar is included under the *Eyemouth* district in the board of fishery returns.

of nets united together in a line, and kept suspended in the water by means of buoys floating on the top. The different lengths of the nets so united are, in fishermen's language, measured by barrels, each length being about the quantity of net a barrel would hold. A barrel of nets is generally 90 yards in length. The depth of the net is from 20 to 24 feet, and when new, it costs from L.4 to L.5. A whole train consists, according to the wealth of the fishermen, of from 7 to 25 barrels of nets. It measures from 600 to 2000 yards in length, and its value is from L.25 to above L.100. A strong rope runs along the back of the train, which is called the "back rope," and to this the buoys are attached by short ropes for floating the net in the water. In the narrow waters of Loch Fyne, about Tarbert and its neighbourhood, where the Loch is some four miles wide, the average length of train runs from 8 to 15 barrels, or from 650 to 1350 yards. Further down, between Arran and the Argyllshire coast, in the Sound of Kilbrennan and towards Campbeltown, the longer trains of 1500 or 2000 yards are used, and in the same way on all parts of the coasts, long trains are preferred wherever there is sufficient space for them.[1]

Owing to the great bulk of a train of nets, a boat of large size is required, and accordingly, the regular full-sized drift-net boat is one of a superior description, the best and largest class costing from L.60 to L.100, with a crew of from four to six men, though an intermediate kind, costing less, with a single lug sail, and from two to three men, is sometimes used. In Loch Fyne and about the Clyde, the greater part of the drift-net boats are sloop-rigged, with three sails, requiring some degree of management. These boats often make voyages of considerable length, such as to the Isle of Man and the Island of Lewis, whereby the crews become acquainted with the use of the compass, are inured to the sea, and gain the rudiments of seamanship—making this class of boat a valuable nursery for seamen.

The nets having been put on board, the boats sail to those parts of the loch, or adjoining sound, or sea, where it is expected fish will be found. As almost all the fishermen take the same signs as a guide for finding fish, the boats thus gather together in fleets in particular spots, and so long as fish are found there, or are hoped for, the boats do not remove, but continue fishing in the same place.

The process of setting a drift-net is as follows: as soon as a boat reaches the fishing ground the first net of the train is put out over the stern, and the boat is gently sailed or rowed, the men in the stern carefully tending the nets as they pass out, till the whole train is in the water. The boat is then made fast to the train by a rope of about 20 fathoms, called the "swing rope," and both boat and train drift together with the wind or tide. The further end of the train, according to the situation and the nature of the ground, is either left floating, or fixed by a rope called the "tailing rope," to an anchor or stone, and sometimes is made fast to the shore. Putting the net out of the boat is technically called "shooting the net;" and drift-net boats, to give room to each other, and prevent fouling and collisions from unequal drifting, usually shoot so as to allow a clear space of about 60 yards between the train of each boat after the whole have shot. The nets are always shot at or soon after sunset, and the fishing goes on through the night.

It requires some time to shoot a train of nets, but it takes still longer, and is a work of more labour, to haul it in. The drift-net boats therefore are particularly loath to shift their ground often, by which so much time and strength are expended. Still, however, to prevent too long lingering on unfavourable ground, an arrangement or privilege is admitted among fishermen of lifting out of the water parts of each other's nets to examine, and see whether fish are in them or not. This is technically called "preeing," and when no fish are found, the news spreads, and frequently becomes the signal for the boats to haul in their nets, and move away. This "preeing" is viewed with some jealousy. The immense length of the trains, and the distance of the owners from almost every part except just the last net to which the boat they are lying in is fixed, make them fear plunder or injury of their nets under a false pretence. For the same reason, the moving about of small boats among trains of nets is much disliked and objected to, and drift-net boats seldom or ever take any small boat with them. A small boat, besides being rarely wanted, and therefore rather an incumbrance, is regarded by fishermen as giving most mischievous opportunities for pilfering from nets, and they set their faces against it. The fish are caught by *meshing*, that is, by pushing their heads and gills through the interstices of the net, from which they have no power to withdraw them.

In former years, in Loch Fyne and its neighbourhood, at the early part of the season, it was common for drift-net fishermen to take off from their trains, perhaps two or three barrels of nets, and securing one end to the shore, carry the other end out into the loch, and make it also fast there by an anchor or stake, thus forming a set net. This net was technically called a "trammel net," and was often very successful in taking herrings of large size, and fine quality, the widest meshed nets being generally selected for setting as trammels. But the system of drift-net fishing, as above described, is the one almost universally practised on our eastern coast, and is also the usual one elsewhere.

The net distinguished by the herring fishers of Scotland as the *trawl net*, is improperly so called, the real name being "seine net." It consists of a net varying in length from 140 to 170 yards, and from 9 to 14 yards deep. Its value is about L.4, 10s. At each end is a short rope called the "bridle," kept stretched by a wooden spar called the "beam," to which is attached a rope varying from 100 to 200 fathoms in length, called the "drag rope." There are no buoys to the net, but it is kept upright in the water by means of pieces of cork, set about two feet apart. The whole apparatus is light and portable, and easily managed compared with the drift-net. The boats used with it are small, depending chiefly on oars, making no very long voyages, and commonly costing from L.10 to L.20, with crews of four or five men each, more men in proportion to the size of the boat being required for the work of hauling the trawl.

The trawl-net is used in different ways, according as it is to be worked from the shore, or from boats. For using from the shore, it is carried by the trawl boat to a place that appears favourable. The drag rope at one end of the net is handed to a party of men stationed on the shore, who hold it there while the boat rows off, the crew in her laying out the net in a semicircle, and when the net is all out, bringing the drag rope at the other end in with the boat to the land. A full and wide sweep is thus made with the net stretched to the full length of itself and the drag ropes, and a very considerable area of water is embraced by it. It resembles the net-and-coble salmon-fishing, formerly described, only on a much more gigantic scale.

[1] The above statement chiefly refers to, as it was derived from, our western shore. We believe that the designation of "a barrel of nets" originated from the practice which at one period prevailed of carrying the nets *in barrels*, from many places on the Firth of Clyde into the interior lochs, or other fishing-ground, with a view to the saving of stowage in the boats. But we have just been informed that the general custom, both in the west and east, now is for these portions of net to be made 50 yards long, and 15 score of meshes deep, with a back rope of 34 yards in length, and a gable line of about 11 yards; so that each single net now contains at least 374 square yards, and is about 33 feet in depth; of course the *drift* varies in length in accordance with the number of pieces which may be combined.

Scotch sea-fisheries.

On the boat reaching the land, the net is hauled in by the drag ropes, the parties at each rope coming nearer and nearer together to complete the circle. The net thus brings in with it fish of every description, herrings and all others, great or small, whatever may chance to exist within the circle. The object with the trawl-net is not to wait till the fish mesh themselves by entanglement, as with the drift-net, but to shift ground and make as many hauls as possible during the night, sweeping off the whole of the fish in succession at each spot visited.

When fish are not found inshore, the trawls are used in the middle of a loch or estuary, sometimes by means of two boats, sometimes with only one. When two boats are used, one remains fixed; the other rows away from it in a circle, till it comes round again to the first boat. The net is then hauled by the joint crews, the bottom being gathered in with the sides, so as to form a sack in the water. When one boat only is used, the tail end of the net is made fast to a buoy, the boat then rows away, swiftly passing out the net in a circle till it comes round again to the buoy, when the net is immediately hauled in after the same fashion as with the two boats.

This explanation is sufficient to show that trawl or seine net fishing does not require the capital, skill, or seamanship, of drift-net fishing, but that from its nature, and from the capture by single hauls of masses of fish, it gains immense and sudden prizes; while from the rapidity with which this net can be set and hauled again, as well as moved from place to place, a few trawling boats, in narrow waters and convenient situations, may, though only manned with landsmen and not fishermen, carry away many entire shoals of fish, having gone over in rapid succession all the best water. The use of the trawl or circle net, and the dragging a drift-net through the water, in the manner of trawling, for the purpose of taking herrings, are both prohibited by the 6th clause of the act 14th and 15th Victoria, cap. 26.

The drift-net and the trawl-net fishermen are greatly opposed to each other. The drift-net men are by much the most numerous, and wherever the trawl-net is used, whether it be on the west or east coast of Scotland, the same objections are stated against it, though in greater or less degree, according to locality. The drift-net men say (especially as regards Loch Fine, and other narrow waters), that trawling disturbs and disperses the shoal of fish as it enters from the sea, and scares it away. They call this "breaking the eye of fish," and they say that when the eye or centre of the shoal of herrings is broken in its progress up a loch, the body of fish are scattered and lost,—that they do not reunite in a shoal and continue to swim together after the manner of herrings, but are split up into separate fragments, which, thus detached from the main body, seek back to deep water or the open sea for safety. They say that the herring is a timid and easily frightened fish, and therefore, for the good of the fishing, that its capture should be effected without disturbance of the water, and by the quiet process of letting the fish mesh itself. Those thus caught remain in the net to all appearance swimming, and no shock is given to the shoal. Whereas trawl-nets are brought with violence against the main body, forcibly driving it back, with much disturbance in the lower parts of the water.

They further affirm that the operation of the trawl-net in catching large masses of fish of all sorts and sizes, and jumbling them up together, bruises and injures many, which being unsaleable, are left dead or dying in the water, thus destroying the fishing grounds. That the small fry of the fish are caught indiscriminately along with the full-sized parents, to the injury of the brood. That herring spawn is destroyed. That no trammel-nets can be set, because trawlers take possession of the bays, and the trawls would tear down any other nets placed there. That drift-nets in the same way are driven out of the bays and best places into the middle of lochs, and other unfavourable situations, because the trawl-net must inevitably foul the drift-net and destroy it, if it is used near it. That trawling-skiffs often come among the trains of drift-nets, where the crews trawl by making fast their drag ropes to the back ropes of the drift-nets, thus intercepting and carrying off the very fish that are about to be captured by the latter. That in moving about among the trains, these crews are frequently guilty of lifting the drift-nets, and stealing the fish. That from malice they often stab the drift-net buoys, and thus sink both nets and fish, which are thereby totally lost. That trawlers, in general, are not genuine fishermen (though of course there are individual exceptions), but interlopers, consisting of tradesmen, small farmers, farm servants, and other landsmen, who may have sufficient skill to manage a boat in fine weather, but who do not follow sea-fishing as a profession, although they may venture upon a kind of gambling speculation, with the chance of earning a twelvemonth's income by a few weeks' work. That they take from drift-net men the large class of herrings which were formerly caught by trammels, and which would be so caught again if trammels could be set. That the extravagant gains of great trawling hauls are thus monopolized by a few, and those not regular fishermen, while the same quantity of fish divided among men with trammels and drift-nets, would support and enrich the families of many real fishermen. That trawling can never be a general mode of fishing for herrings, as it is capable of being carried on only in certain localities, and under certain conditional circumstances, and thus the returns of such a system must always be confined to a few persons who are enabled by it to fill the markets suddenly with fish, from the enormous hauls they meet with. These, however, which are often very much the result of accident, deprive the established fisherman of his fair livelihood, by rendering his fish unsaleable except at prices which entail on him a positive loss. That in Loch Fine there has been a falling off in the quantity of fish since trawls were adopted, now not much more than a dozen years ago.

The trawl-net fishermen, on the other hand, deny all these allegations. They state that they are able to take larger and finer herrings than were ever known till the trawl was introduced. That this large herring is a slow swimming fish, which will mesh but seldom, and can only be caught with certainty by being forcibly pent up in a net. That herrings being a timid fish, will not mesh during the early summer nights, because there is too much light, and they see the drift-nets. To catch them at that time of year, therefore, they say they must be encircled by a trawl-net. That they also catch mackerel, and other sorts of fish, with the trawl-net, when fishing for herrings. That a small capital is made to produce a comfortable livelihood. That the produce of the sea is free to all, and as marine fish call no man master, they may be taken at any season, by whoever is able, and in whatever manner can be devised.

The trawlers also deny that the fishing has suffered from their operations, or that they interfere with drift-nets, or any other kind. On the contrary, they affirm that by working with their trawl-nets along shore, they often drive the herrings into the middle of the lochs, to be captured by the drift-nets laid out there, and from which they would otherwise escape.

While the statements of the two parties are thus opposite and conflicting, there is one point which admits of no doubt, viz., that trawling any kind of herring-net practically supersedes the provision of the act 48th Geo. III., cap. 110, sec. 12th, requiring the mesh to be one inch from knot to knot; for the act of drawing the net through the water in a circular form, immediately narrows the mesh below the inch-square, even though it should be in itself somewhat more than an inch from knot to knot. It is from this effect, and from the packing up of the net with a solid accumula-

Scotch sea-fisheries.

tion of fish, that under-sized herrings and fry are frequently taken and destroyed by the trawl-net. If trawl-net fishing for herrings could be admitted without detriment to the herring-fisheries, as is stated by its advocates, it seems to be unreasonable to maintain any legislative provision, such as that just cited, or to prohibit drift-net fishers from using any size of mesh they please.

The inch-mesh is universal over the coasts of Great Britain, and, we believe, is observed in Ireland. It forms an article in the fishery convention with France, and fishermen of that country are required to adhere to it as strictly as our own. Whatever may have been its origin, the meaning of the regulation is obvious, viz., that full and sizeable herrings should alone be caught, and the young allowed to grow. The medium mesh of an inch accomplishes both these objects. How far they are important, or could be continued were all restriction upon the size of mesh removed, is matter of opinion and conjecture; but a mass of netting in the sea, with meshes drawn close and thick, certainly seems calculated to debar the natural progress and circulation of the fish among the different boats, must undoubtedly capture the young fry, and would probably, from its increased visibility of cordage, be apt to frighten away the heavy shoals of mature fish. The existing regulation for the size of mesh is popular, and seems to be approved of by fishermen of all classes.

Trawling for herrings is practised on the west coast of Scotland, chiefly in Loch Fine, the Kyles of Bute, the Firth of Clyde, especially on parts of the Ayrshire coast, and in Loch Ryan. It is also occasionally resorted to in some of the other Lochs. The most active and determined trawlers on the west coast are those of Tarbert, a fishing village halfway up Loch Fine. On the east coast of Scotland, it is chiefly practised in the Firth of Forth, and occasionally, but slightly, in the Firth of Tay, Beauly Firth, and Firth of Cromarty. The act for its suppression is frequently enforced.

There is, undoubtedly, some disadvantage in establishing a uniform standard of mesh, or one general law for herring-fishing, that admits of no exceptions; for there may be cases, either in respect of the time of year, or of a breed of herrings of smallish size, where a power of relaxation and adaptation might be found beneficial. There is reason to believe, that in certain lochs of the Highlands, and in other parts, herrings occur below the average dimensions, although quite fit for food, and that for these, nets with meshes less than an inch from knot to knot, might be used with advantage.

When a train of drift-nets has remained in the water for a sufficient length of time to allow the herrings *to mesh*, the nets are raised, and the fish carefully shaken out of each successive portion as it is taken on board. This is a much better plan than one too frequently followed, of allowing them to remain among the meshes till the whole mass is taken to the shore. By the former practice, the fish are much less liable to be bruised or broken, and so do not so soon become soft or tainted. An additional advantage is that the nets are all the sooner ready to be spread out or hung up to dry. If not intended to be consumed in the fresh state, the sooner salt is applied to herrings the better, as it secures the adhesion of the scales, so important to the after appearance of the fish. For this purpose salt should be sprinkled over them, as they are emptied in successive portions from the cran measure into the great receiving or gutting trough. All herrings should if possible, be gutted, cured, and packed on the day they are caught.

All along the inner harbour, and in almost every street and quay, of the town of Wick, as well as within many large inclosed yards and covered buildings, there are numerous square wooden boxes as big as ordinary-sized rooms, the containing sides, however, being only two or three feet high. Into these huge troughs the herrings are carried from the boats as soon as possible after they arrive. There they are all tumbled in helter-skelter, in a long-continued stream of fish, until the boats are emptied or the troughs are filled. Then come troops of sturdy females of various ages and complexions, each armed with knife in hand, who range themselves around the fishy chambers,—the process of gutting immediately commences, and is carried on with such ceaseless and untiring activity, that the unaccustomed eye can scarcely follow the quickness of their manipulations. One woman will eviscerate about two dozen of herrings in a minute; and when nearly 2000 of them are working at that rate, with but brief intermission from early morning till the close of day, the amount of disembowelment may be more easily imagined than described. This important process is effected in the following manner:—The practitioner takes a herring in her left hand, its back lying in her palm, and inserts the point of her knife into the near side of the neck, bearing well down upon the backbone, and making the weapon protrude a little through the other side. She then gives the knife a turn, and pulling it outwards and upwards, with an opposing pressure of the thumb, she draws forth in the first place the gills, stomach, and intestinal canal, and tosses them into an adjoining barrel. She then inserts the knife a second time, and by a peculiar twitch removes what is called the crown gut, or cæcal appendages, and liver. There are thus two actions performed, each of which seems to occupy about a second of time. This is the ordinary Scotch, and we prepresume English, practice. The Dutch method is somewhat different. They leave in the crown gut, and so with them a single pull suffices to remove whatever is to be taken away. This latter mode is partially followed in this country, as being best adapted for the continental market, where it is believed that the crown gut has a powerful influence in improving the flavour of the fish, and where the appearance of the herring is held to be injured if it is removed.

These fair gutters usually work together in little companies of two or three, so that while one is filling a measure with her gutted fish, another carries them off to be *roused*, as it is called, that is, cast into other vats or barrels, then sprinkled with salt, then more herrings and more salt, and next a brawny arm plunged among them far above the elbow, thus mingling them together, and so on till the space is filled. They may lie a longer or shorter time in this state, according to the supply of labour at command, and the immediate necessities of gutting and rousing; but the next usual step in the routine is for a third hand to remove those herrings from the second vats or vessels, and re-salt and pack them carefully, every successive row crossing at right angles that which precedes it. Herrings intended for the foreign market are usually arranged with their backs downwards, while those for the Irish market are preferred when packed flat, or more upon their sides. Each row gets a fresh sprinkling of salt until the barrel is filled. The head of the cask is then laid loosely on, the contents being allowed to settle down, or *pine*, as it is called, for a time; which they soon do so considerably as to admit of each cask receiving another row or two, with additional salt, before being closed by the cooper. The barrels should then be headed up, tightened in the hoops, laid upon their sides, and placed under cover, so as to be shaded from the sun's rays, which are injurious to the fish. They should also be rolled half over every second or third day, until they are bung-packed; which process, if the after intention is to receive the official brand of the board of fisheries, must not be sooner performed than after the lapse of ten free days from the date of capture. "When the pickle has been sufficiently poured off, a handful of salt, if required, should be thrown around the inside of the barrels, and the herrings should be pressed close to the inside of the casks, and additional fish,

Scotch sea-fisheries.

of the same description and date of cure, should be packed in until the barrel is properly filled; after which it should be flagged, headed, blown, and tightened, and the curing marks scratched upon the sides. The barrel may then have its pickle poured in, and be finally bunged up."[1]

An injurious practice prevails among our people, of allowing the gutters and packers to stand "idle in the market-place" until a large quantity of herrings is poured into the curing vats. Every hour lost between the capture of the fish and their being salted down into the barrel produces injury. The gloss of their marine freshness passes away as the dew of the morning, and it is the preservation of this natural splendour, so to say, from the cure commencing on board ship almost the minute they are taken from the water which causes Dutch herrings to be so highly prized. The British curer should bear this in mind, and remember that while he is in possession of great local conveniences from curing on shore, these may be counterbalanced by some disadvantages which it requires care to obviate. The Dutch herrings escape all exposure to the sun. They pass at once from the sea to the salting tub. But the British fish are frequently for hours beneath a burning sun, while the boats are delayed, by calms, or are beating up to their desired haven against adverse wind and tide. The curers too often add to this delay, by waiting till such an ample supply has been accumulated as will enable all the gutters and packers to set to work simultaneously. The general adoption of the plan of placing sheds or covers of some kind over the curing tubs, would be very advisable. In many places the curing under cover is totally disregarded, although it is obvious that the reputation of British herrings can never be perfectly kept up while improvements so easy to accomplish are neglected. Our Banff herrings began to rank high at an early period, in consequence of their careful cure; and even now, when no doubt many other places are equal, it is the custom of several of the Caithness curers to brand the word "Banff" upon their barrels, although they have no connection with that locality. The cause which we have seen assigned for the excellence of the Banff herrings is, that they are usually caught in small or moderate quantities, so that more pains can be bestowed upon their preparation. On the Caithness coast they are often got in overpowering numbers, so that some of them may be too hastily cured. Of course, the presence and inspection of the fishery officer checks any bad effect from this, so far at least as concerns the guarantee afforded by the application of the crown brand.

We understand that the commissioners of the Board of Fisheries, with a view to test the progress that has been made in the cure of British herrings, instituted, some seasons back, in Edinburgh, a trial of different sorts, compared with some of the finest Dutch samples. The conjoined kinds were submitted to the taste of competent judges, and were privately marked by distinguishing cyphers unknown to those who had to give their opinion. There was no other clue to the quality than what the skill of the judges could supply. The result was highly satisfactory: for by a unanimous decision, two classes of British herrings—viz., Maties and Crown Full Brand—were declared to be superior to Dutch of the finest quality, which had been imported expressly for this competition. Of course, we must not build too much on this, as a few selected and super-excellent samples may not necessarily indicate, or at least prove, the superiority of the entire cure considered in relation to some hundred thousand barrels. That superiority, from causes already mentioned, probably still abides with the Dutch. The experiment was renewed during an after year, and was conducted in the same public manner, and with similar arrangements to prevent the judges from having any clue to the kind of herring set before them. The result of this other trial was different, although it testifies to the freedom from favouritism of those concerned. The Dutch were decided to be the best, though only in a slight degree; and a more searching trial on the succeeding day proved that the prize, determined with difficulty, had been justly awarded. To an ordinary purchaser, it is probable that no difference would have been perceptible, and the British barrels from which the samples had been taken would no doubt have passed for Dutch, as they often do in the Rhenish provinces. But in every particular these Dutch herrings showed a delicacy of treatment evidently the result of long experience, and the nicest tact. In both trials, however, it was evident how prodigious an advance had been made within a few years in the British mode of cure, when it was able to stand successfully, under the keenest criticism, so close a comparison with that of the Dutch.

Scotch sea-fisheries.

The lively interest taken by the Dutch government in the furtherance of their fisheries, is shown by the fact of their placing superintending men-of-war to aid their fleet of fishing vessels while engaged off the coasts of Scotland and the Shetland Islands. They also order a government steamer of great power and large dimensions (the "Cerberus" was heavily armed, with a crew of 100 men), to attend upon the boats, and receive on board the early catch of fish, so that these may be carried off with all expedition, to secure the highest price in the continental markets. The importance of the Dutch fishery was perceived by the nation at an early period, and their inroads upon our own resources were bemoaned by many writers. "It maketh much," says Sir John Burroughs, in his *Sovereignty of the British Seas*, "to the ignominy and shame of our English nation, that God and nature offering to us so great a treasure, even at our own doors, we do, notwithstanding, neglect the benefit thereof, and by paying money to strangers for fish of our own seas, impoverish ourselves to make them rich." When the population of the States General was estimated in 1669, it was found that, out of a total of 2,400,000 persons, 450,000 were either fishermen or connected with the building and equipment of ships and boats belonging to the fisheries. So the pensionary De Witt scarcely exaggerated when he stated that every fifth man in Holland earned his subsistence by the sea, that the country derived her main support from it, and that the herring-fishery ought to be regarded as the right arm of the republic. In the height of her prosperity and power, it is said that not less than 3000 boats of various kinds were employed off her own coasts, besides 800 vessels, of from 60 to 150 tons burden, occupied on the British seas in the capture chiefly of cod and ling. She had, moreover, between the mouth of the Thames and Buchan-Ness, a fleet of 1600 busses engaged in the herring-fishery, and employing so many minor vessels in the carrying of salt and cured fish, that the total number of shipping amounted to 6400, calculated to give employment to 112,000 mariners and fishermen. The Dutch themselves admitted that the wealth and strength of the United Provinces were derived from their sea-fisheries, the importance of which was emphatically indicated by an expression in common use among them, that "the foundation of Amsterdam was laid on herring bones." Of course there was this essential difference between the Dutch and ourselves, that they grew no grain, were scarce of cattle, and possessed few manufactures, and so depended largely on the produce of the sea, to enable them to effect the required exchanges with other countries.

[1] *Directions for taking and curing Herrings, and for the curing of Cod, Ling, Tusk, and Hake.* By Sir Thomas Dick Lauder, Bart. Edinburgh, 1846.

Scotch sea-fisheries.

We shall now endeavour to illustrate by tables the extent and value of our herring fishery.

Abstract of the Total Quantity of White Herrings Cured, Branded, and Exported, in so far as the same have been brought under the cognizance of the Officers of the Fishery, *from the* 1*st of June* 1809, *when the system hitherto in force for the Encouragement and Improvement of the British Herring Fishery took place, to the* 31*st of December* 1854; *distinguishing each Year as under, and the Countries to which they have been Exported. The Periods are calculated as ending* 5*th April each year up to* 1845, *and from* 1845 *they are calculated as ending* 5*th January. After* 1850 *the Table includes Scotland and the Isle of Man only.*

N.B.—In the Six Years ending 5th April 1815, the Bounty on Herrings Cured Gutted was 2s. per Barrel, while there was a Bounty at the same time of 2s. 8d. per Barrel, payable by the Excise on the Exportation of Herrings, whether Cured Gutted or Ungutted, but which ceased on the 1st June 1815; in the Eleven Years ending 5th April 1826, the Bounty on Herrings Cured Gutted was 4s. per Barrel; in the Four succeeding Years, the Bounty was reduced 1s. per Barrel each Year till the 5th of April 1830, when it ceased altogether, and has not since been renewed.

It will be seen from the preceding abstract that the quantities exported, whether to Ireland or elsewhere, vary greatly. The recent falling off in Ireland followed the famine, and the failure in the potato crop. Salt herrings cannot be eaten alone, and the common Irish have little or no bread. The exports to "places out of Europe" were chiefly to the West Indies, but the changed condition of what was formerly the slave population of those islands has caused a great alteration in their diet. They do not now voluntarily purchase to any great extent what they were formerly *supplied with* in their state of bondage. It will be observed, however, that the general exports to the European markets are on the whole greatly on the increase, and no doubt, under an alteration of import duties, admit of an enormous enlargement.

Our next table exhibits in local detail the fishing of 1854, of which season the totals are given at the close of the preceding abstract.

An Account of the Total Number of Barrels of White Herrings which have been Salted or Cured on Board of Vessels fitted out for the Fishery, or Cured by Fish-Curers on Shore, in Scotland and the Isle of Man, in the year ended 31*st December* 1854; *distinguishing the Districts where Landed or Cured.*

Leith	6,695½	Wick	126,625¼
Eyemouth	25,353	Lybster	41,550
Greenock	8,456	Helmsdale	31,785
Glasgow	12,410	Cromarty	14,783
Rothesay	2,399½	Findhorn	31,566
Inverary	20,632½	Banff	46,995¼
Loch Carron and Skye	2,056	Fraserburgh	44,215
Loch Shildag	658	Peterhead	66,691
Loch Broom	1,328	Anstruther	77,646½
Stornoway	31,515	Isle of Man	13,797¾
Shetland Isles	9,009		
Orkney Isles	20,394½	Total	636,562
In addition to the above, there was taken and sold or otherwise consumed in Scotland and the Isle of Man, the following amount of barrels or crans, not cured, but disposed of fresh, viz.			103,789
Thus making a grand total for 1854 of			740,351

We owe to Mr Alexander Wellmann, a Prussian merchant, some valuable statistical information regarding the conditions of the herring market at Stettin, to which port a large proportion of our Scotch herrings are exported. The following is a note of the quantities of the Stettin importations for a period of twenty-seven years:—

Years.	Barrels.	Years.	Barrels.
1824	15,468	1838	40,209
1825	18,160	1839	49,456
1826	7,695	1840	73,949
1827	15,082	1841	50,732
1828	13,478	1842	62,135
1829	14,449	1843	143,659
1830	33,866	1844	105,097
1831	13,077	1845	81,189
1832	31,837	1846	104,372
1833	31,711	1847	112,260
1834	19,060	1848	103,402
1835	26,875	1849	147,103
1836	28,227	1850	116,538
1837	36,309		

Mr Wellmann records his opinion as follows regarding the advantage of the brand:—"I take this opportunity of stating, that the official brand of Scotch *crown* and *full* branded herrings obtains the greatest confidence, not only in our market, but also in the interior of Germany, where the meaning of that brand is understood, and my firm belief, and also that of other people engaged in this branch of business, is, that it would be injurious to the trade should the brand cease to exist, for Scotch herrings are only sold in small quantities in this market and the neighbourhood; they are chiefly sent great distances, of from 100 to 800

[1] For year ending 5th January.

[2] For year ending 31st December.

Scotch sea-fisheries.

miles English, into the interior of Germany and Poland, either by orders or offers, without the assistance of commission merchants, for the great expense of forwarding them does not permit any commission to a third party. The great distance likewise prevents dealers from inspecting the herrings on the spot here, who therefore make their purchases solely on their trust in the official brand, knowing that the fish must be selected well, and properly cured; that the barrels be of the legal size; and that they require to be well and tightly made before the brand can be affixed.

"These herrings are generally forwarded by crafts which are often six to eight weeks on their passage, and it frequently happens that a great fall in the market takes place during that time, and, should the official brand be removed, dealers in the interior might easily take advantage of such falls, for it would not be difficult to find complaints, such, for instance, that the fish were not properly selected or well cured, that the fish had too much or too little salt, or that the barrels were of a smaller size (for no one can then say of what size the barrels require to be), and, as most herrings are sold on credit, they would consequently be often stored at the risk and the expense of the shipper, and perhaps in markets where that person who purchased them is the only dealer.

"Part of the present business consists of consignments by the curer in Scotland, who receives an advance when the herrings are shipped; and my opinion is, that this advance will cease to be given as soon as the official brand is removed, as our merchants here are then unable to judge what proceeds they will receive out of them when sent to the interior, and consequently the Scotch curer must feel it seriously whenever this brand is taken away, as he would not be able to embark so much capital, and from him it must show its influence upon the fishermen, and those people connected with the fishing."[1]

We may here observe, that although a large quantity of Norwegian herrings are exported, they are not cured under the superintendence of the government, and as therefore no certain reliance can be placed on their quality, they are scarcely ever sent into the interior of continental countries, but, so far at least as Prussia is concerned, are chiefly consumed at Stettin and the neighbouring provinces, from whence dealers are able to proceed for a detailed inspection; and hence Norwegian fish are in general more difficult to be sold than Scotch. We understand that in some places in Norway local boards have of late been formed, and already herrings shipped from these ports both find quicker sales, and are sent further into the interior. The sale of Norwegian herrings, however, greatly depends upon the prices of Scotch fish, for when the latter are low the former are more difficult to be disposed of, and the Prussians prefer our fish to those of the Norwegian cure, because they are of superior quality, better preserved, and the barrels contain a greater number. Dutch herrings must still be regarded as belonging to "high art" in their style of cure, but the difference in price is great, and so the Scotch kind abroad still find a readier sale. But the improved cure, and increased cheapness, of our fish, continue to operate in our favour, as the following, from the preceding report, will suffice to show:—

In 1834,	barrels	of Dutch herrings received at Stettin,			4,546
...	...	of Norwegian	do.	...	53,981
...	...	of Scotch	do.	...	19,960
In 1850,	...	of Dutch	do.	...	568
...	...	of Norwegian	do.	...	12,507
...	...	of Scotch	do.	...	116,538[2]

In 1849 our exportation to Stettin amounted to 147,103 barrels. That year had produced the most extraordinary take of herrings ever recorded in Scotland, and so gave the power, while Prussia afforded the opportunity, of an ex-

[1] Letter to George Traill, Esq., M.P., in *Report on British Fisheries* for 1850.

[2] We may here note the duties charged abroad on herrings. In the confederated states of Germany (the *Zollverein*), the present duty is one dollar per barrel, equal to about 3s. sterling. *Austria* charges 2 gulden 30 kreutzers per cwt., making about 15s. sterling per barrel, a prohibitory duty nearly equal to what is often the prime cost. *Russia* (we know not her present views regarding the Baltic trade) used to make a difference in her tariff between Scotch and Norwegian herrings, the former paying an import duty of 1 ruble 30 cops silver per barrel, equal to about 4s. 6d. sterling, the Norwegian being charged only 35 cops silver, being about 1s. 3d. sterling per barrel. The duty in *Poland* was formerly lower on Scotch herrings, but has been raised to that of Russia since the 1st of January 1851, and we have lost, in the meantime, a good market as concerns that "nationality." In *France* the duty is from 37s. to 40s. per barrel, more than double the actual price, and so of course it is entirely prohibitory. In *Naples* it is still nearly as high as it formerly was in Belgium (from 12s. to 15s. per barrel), but we know not its precise amount at the present time. From *Spain* and *Portugal* we understand that our herrings are excluded, we presume by reason of the excessive duty. None are ever sent there. The Spaniards, however, consume the finest of our cured cod and ling, on which the duty is as follows:—*Direct from the place of cure,*—In Spanish vessels, L.6, 10s. per ton; in British vessels, L.8, 13s. per ton. *Indirect, or from a port not at the fishing-ground,*—In Spanish vessels, L.10 per ton; in British vessels, L.12 per ton.

The following are the duties on British fish in *Belgium*, according to the convention, signed at London, March 22, 1852:—

	Francs.	Cents.
Herrings—pickled or drysalted, per barrel of 150 kilogramme, gross weight,	13	...
Others, per thousand,	8	...
Lobsters—destined for the national beds, per 100 francs value,	6	...
Others, per 100 francs value,	12	...
Oysters—destined for the national beds, per 100 francs value,	1	...
Others, per 100 francs value,	12	...
Cod—pickled or drysalted, per barrel of 150 to 160 kilogramme, gross weight,	22	50
Stockfish—per 100 kilogramme,	1	...

The above conditions were to come into operation on the 10th of April 1852. They are a modification and reduction of the former tariff, but certain of the duties are still so high as to be in fact prohibitory. The weight of 150 kilogramme is about equal to that of a Scotch barrel of herrings, and the imposed duty is 13 francs, or about 11s. sterling. Under such a tax on importation the trade will never open. The smoked or red herrings are more leniently dealt with, a duty of 8 francs, or 6s. 8d., on the thousand, being one farthing on every three herrings. This, it is thought, may admit of an increased consumption, and produce a profit to our people. Flanders is noted for its industrial and concentrated population, and has now the advantage of a net-work of railways. Within a circumference of half a day's journey we have the following large cities:—Brussels, 140,000 inhabitants; Ghent, 100,000; Liège, 80,000; Louvain, 55,000; Antwerp, 90,000; Bruges, 60,000; Mons, 30,000; Namur, 30,000; Malines, 50,000;—to say nothing of several others of less note. An established taste for herrings, of whatever kind or colour, among such hordes of hungry people, would assuredly be of great advantage both to them and us.

We may add that the *transit duties*, that is, the tax imposed on transmission into countries not pertaining to the place of original importation, have an influential bearing on prices and profits. Prussia has recently reduced her transit duties on herrings from 1s. 6d. to 4½d. per barrel. Those imported by Russia used to be charged 10 silver groschen, equal to about 1s. sterling per barrel, on the Oder as well as Vistula, while on the river Elbe it is only 2½. Holland charges about 3s. sterling per barrel for the transit of herrings on the Rhine. Denmark levies a duty of 3d. sterling per barrel on all herrings that pass through the Sound. Hanover charges one halfpenny per barrel for such as pass the Elbe at Stade.

Scotch sea-fisheries.

cessive exportation. The capture during the season of 1849 was as follows:—

	Barrels.
Total quantity cured,	770,698
Total quantity disposed of fresh,	381,281
Grand Total,	1,151,979

Of the former, 149,505 barrels were cured at Wick alone. Of the latter the following large quantities were taken and sold fresh at the stations of the Firth of Forth, viz.:—

	Barrels.
Anstruther,	24,243
Eyemouth,	34,243
Leith and Burntisland,	20,000
	78,486

Yarmouth[1] produced during that same season 113,574 barrels of fresh herrings, the London station 26,224, and Liverpool and the Isle of Man 27,600. The grand total for 1849 includes the English stations, which yielded 209,362 barrels, leaving for Scotland and the Isle of Man 942,617 barrels. The season of 1853 was also very productive, the returns for that year, exclusive of the English stations, giving a total of 908,800 barrels.

The value and importance of this great fishery as a seafaring occupation and marine nursery are too obvious to require mention. The following abstract is exclusive of the English stations, and also of between four and five thousand men engaged in the *export* fishing trade.

Scotch sea-fisheries.

Total	32,649	2,404	42,954	3,499	72,414	L.225,830	L.303,666	L.57,924	L.587,420[3]

[1] The Yarmouth herring-fishery is chiefly an autumnal and early winter one, but it seems that a summer season is also enjoyed there. We are informed by Mr John Miller, the intelligent inspector-general of the fisheries, that "some of the Scotch boats returned, after an absence at the Yarmouth herring-fishery, with L.300. These boats have now (2d August 1855) begun business again off Dunbar."

[2] The above numbers are exclusive of the southern fishing stations. When these were included the total amount was much larger. Thus, in 1846 the report, as made up for the preceding season, gives the total number of persons employed as 99,065, besides 1530 curers, and nearly 5000 men engaged in the export trade. The great season of 1849 gave occupation to 98,326 persons, besides 1619 curers, and 6101 men engaged in the export trade. It ought also to be borne in mind, while estimating the importance of our fisheries as a field of industrial occupation, that these high figures are altogether irrespective of the numerous individuals employed in our salmon-fisheries, and in those for turbot, flat-fish, mackerel, and many other kinds.

[3] The returns of the board of fisheries now give estimates only for Scotland and the Isle of Man. When London, North Sunderland, and Whitby were included, the value of the materials employed was of course much greater. Thus, for the season ending in the winter of 1846, the boats were estimated at L.702,206; the nets at L.481,262; the lines at L.92,371;—making a total of L.1,275,839.

Scotch sea-fisheries.

We shall now say a few words regarding *red herrings.* It is believed that the taste for these, when the smoking process is carefully performed, is on the increase, and might be turned to the advantage of Scotland. Our north-eastern stations, say from Peterhead to Caithness inclusive, have great facilities in the way of cure as well as capture, and it ought to be understood that the super-excellence of a red herring depends both on its original state and its subsequent mode of treatment. Smoked herrings are made from salted ones. They are converted pickles, so to say, and have not always been in the best condition when committed to the brine. But if allowed to lie there for any considerable length of time, they must be steeped in fresh water to remove a portion of the salt previous to smoking, and it is by this intervening process that the quality is deteriorated. There is a certain period during which herrings may be removed at once from the pickle to the smoking-house, and there is a longer time after which they must be steeped. Yarmouth bloaters are among the best of things, but our southern neighbours labour under this great disadvantage, that their fishing is chiefly a winter one, when herrings are seldom in prime condition, while along our north-eastern shores they are caught in the months of July and August, when these fish are in perfection. The cure may be good, but the southerns have not the same articles to begin with. To use Mr Thomson's illustration, a Holstein or Yorkshire ham may have every attribute of excellence in the cure, but as the animal has not lived in the woods of Westphalia, so its flesh has not the sweetness and flavour imparted by the acorn.

A larger outlay of capital is called for to carry on a manufactory of smoked herrings than simply to cure with salt and pack into barrels. It takes a house of considerable size to hang what may make up 300 barrels at one time. The herrings must hang on the smoking-spits for three weeks, and as the prime of the fishing lasts only about six weeks, the house can be filled only twice, if a lengthened lie in pickle and the steeping process are to be avoided. To do the thing in perfection, the produce of a considerable number of boats would be required at once, because if a fortnight from the commencement of the fishing were allowed to elapse in the filling of the smoking-house, the curer would have no opportunity of filling it a second time, at least with freshly pickled and unsteeped fish. A change is said to have taken place in the taste for red herrings. They were formerly preferred of a silvery brightness instead of a golden yellow, and to produce the former state only a few hours' smoking was required. Of course these did not keep, and were sorely distressed by sultry weather. But the taste is now tending rather towards a complete cure, that is, a three weeks' careful and continuous smoking, after which a herring of originally sound constitution will keep almost as long as an Egyptian mummy, and be much better eating in the end.

Along our eastern shores the smoking of herrings is carried on extensively in Aberdeen, Montrose, Dundee, Burntisland, and Leith, and in the west chiefly in Glasgow. But these localities are not stations for the herring-fishery itself, and so many of our curers have smoking establishments at Peterhead, Fraserburgh, and Wick, where they can obtain a full and immediate supply of fresh fish.

The supply of the home market with red herrings and bloaters was formerly engrossed by the Scotch and Yarmouth curers, but it is yearly becoming more extended, and shared by a greater number. Transit by steam is so rapid from the Hebrides, Shetland, Orkney, and other distant places, to railway harbours, and thence by railways into England, that smoking-houses for preparing bloaters are now in use in Liverpool, Manchester, and Birmingham. At distant fishing stations the herrings for bloaters are slightly mixed with salt in dry barrels or boxes, from which the pickle is allowed to escape to prevent over saltness; they are speedily forwarded to the smoking premises, where they are washed (but not soaked), and smoked for 24 to 36 hours, and then despatched as bloaters per rail for London, or the other great English markets, in barrels, half barrels, or in small boxes each containing 100 herrings. Many of the fishing stations are now regularly frequented by English buyers, who daily purchase and forward herrings to England, fresh or slightly sprinkled with salt, according to the season. When the supply of fresh fish is large, or greater at market than the demand, the surplus is often purchased at a reduced price by resident English dealers, smoked for 24 or 36 hours, and again presented at market in small neat baskets as prime Yarmouth bloaters. This gives the English adventurer an advantage over his distant competitors, which he is not slow to avail himself of, and he frequently sells a part of his own fish at an unremunerating figure, and purchases by agents the fish sent to market on consignment at a lower price than he paid for his own at the curing station.

Another class of red herrings are salted for thirty-six or forty-eight hours at the curing station. They are then washed, but not soaked, and smoked for twenty-one or twenty-eight days. These keep well, and have much of the rich flavour of Westphalian ham. Herrings made into reds for exportation, or those smoked in winter for home use, having been salted and cured in pickle, are soaked from thirty to thirty-six hours, according to quality, and then smoked for periods varying from three to four weeks. The soaking of the fish greatly injures their flavour.

Pilchard-fishery.

Having closed our account of the greatest of our fresh and salt water fisheries, those for salmon and herring, we shall now proceed to notice the capture of other species, of great though unequal value.

One of the most important of our southern fisheries (of which we have as yet said nothing) is that for *pilchards* (*Clupæa pilchardus*), a species nearly related to the herring. This fishery is pursued chiefly off the coast of Cornwall. The fish show themselves while swimming past the Scilly Islands in the month of July, and are there caught with a drift-net. They then advance inland in August, during which month the principal or "in-shore" fishing begins. They visit various parts of the coast until October or November, and then disappear till the ensuing summer. They are occasionally caught off the south-western part of Devonshire, and also near the most southern portion of Ireland, but northwards of these two points they are seldom seen off any other district of the British shores.

"The first sight," says an eye-witness, "from the cliffs, of a shoal of pilchards advancing towards the land, is not a little interesting. They produce on the sea the appearance of the shadow of a dark cloud. This shadow comes on, and on, till you can see the fish leaping and playing on the surface by hundreds at a time, all huddled close together, and all approaching so near to the shore, that they can be always caught in some fifty or sixty feet of water. Indeed, on certain occasions, when the shoals are of considerable magnitude, the fish behind have been known to force the fish before literally up to the beach, so that they could be taken in buckets, or even in the hand, with the greatest ease. With the discovery of the first shoal, the active duties of the 'look-out' on the cliffs begin. Each fishing-village places one or more of these men on the watch all round the coast. They are called 'huers,' a word said to be derived from the old French verb *huer*, to call out, to give an alarm. On the vigilance and skill of the 'huer' much depends. He is therefore not only paid his guinea a-week while he is on the watch, but receives besides a perquisite in the shape of a percentage on the produce of

Pilchard-fishery.

all the fish taken under his auspices. He is placed at his post, where he can command an uninterrupted view of the sea, some days before the pilchards are expected to appear; and, at the same time, boats, nets, and men, are all ready for action at a moment's notice.

"The principal boat used is at least fifteen tons in burden, and carries a large net called the 'seine,' which measures 190 fathoms in length, and costs L.170, sometimes more. It is simply one long strip, from 11 to 13 fathoms in breadth, composed of very small meshes, and furnished all along its length with lead at one side and corks at the other. The men who cast this net are called the 'shooters,' and receive 11s. 6d. a week; and a perquisite of one basket of fish each out of every haul. As soon as the 'huer' discerns the first appearance of a shoal, he waves his bush. The signal is conveyed to the beach immediately by men and boys watching near him. The 'seine' boat (accompanied by another small boat to assist in casting the net) is rowed out where he can see it. Then there is a pause, a hush of great expectation on all sides. Meanwhile, the devoted pilchards press on—a compact mass of thousands on thousands of fish swimming to meet their doom. All eyes are fixed on the 'huer;' he stands watchful and still until the shoal is thoroughly embayed in water which he knows to be within the depth of the 'seine' net. Then, as the fish begin to pause in their progress, and gradually crowd closer and closer together, he gives the signal; the boats come up, and the 'seine' net is cast, or, in the technical phrase, 'shot' overboard.

"The grand object is now to inclose the entire shoal. The leads sink one end of the net perpendicularly to the ground, the corks buoy up the other to the surface of the water. When it has been taken all round the fish, the two extremities are made fast, and the shoal is then imprisoned within an oblong barrier of network, surrounding it on all sides. The great art is to let as few of the pilchards escape as possible while this process is being completed. Whenever the 'huer' observes from above that they are startled, and are separating at any particular point, to that point he waves his bush; thither the boat is steered, and there the net is 'shot' at once. In whatever direction the fish attempt to get out to sea again, they are thus immediately met and thwarted with extraordinary readiness and skill. This labour completed, the silence of intense expectation that has hitherto prevailed among the spectators on the cliff is broken. There is a great shout of joy on all sides—the shoal is secured!

"The 'seine' is now regarded as a great reservoir of fish. It may remain in the water a week or more. To secure it against being moved from its position in case a gale should come on, it is warped by two or three ropes to points of land in the cliff, and is, at the same time, contracted in circuit, by its opposite ends being brought together and fastened tight over a length of several feet. While these operations are in course of performance, another boat, another set of men, and another net (different in form from the 'seine'), are approaching the scene of action. This new net is called the 'tuck;' it is smaller than the 'seine,' inside which it is now to be let down for the purpose of bringing the fish closely collected to the surface. The men who manage this net are called 'regular seiners.' They receive ten shillings a-week, and the same perquisite as the 'shooters.' Their boat is first of all rowed inside the seine net, and laid close to the seine boat, which remains stationary outside, and to the bows of which one rope at one end of the 'tuck-net' is fastened. The 'tuck' boat then slowly makes the inner circuit of the 'seine,' the smaller net being dropped overboard as she goes, and attached at intervals to the larger. To prevent the fish from getting between the two nets during this operation, they are frightened into the middle of the inclosure by beating the water at proper places with oars, and heavy stones fastened to ropes. When the 'tuck' net has at length travelled round the whole circle of the 'seine,' and is securely fastened to the 'seine' boat at the end, as it was at the beginning, everything is ready for the great event of the day—the hauling of the fish to the surface.

"Now the scene on shore and sea rises to a prodigious pitch of excitement. The merchants, to whom the boats and nets belong, and by whom the men are employed, join the 'huer' on the cliff; all their friends follow them; boys shout, dogs bark madly; every little boat in the place puts off crammed with idle spectators; old men and women hobble down to the beach to wait for the news. The noise, the bustle, the agitation, increases every moment. Soon the shrill cheering of the boys is joined by the deep voices of the 'seiners.' There they stand, six or eight stalwart, sunburnt fellows, ranged in a row in the 'seine' boat, hauling with all their might at the 'tuck' net, and roaring the regular nautical 'Yo-heave-ho!' in chorus! Higher and higher rises the net; louder and louder shout the boys and the idlers. The merchant forgets his dignity, and joins them; the 'huer,' so calm and collected hitherto, loses his self-possession and waves his cap triumphantly. . . . The water boils and eddies; the 'tuck' net rises to the surface, and one teeming, convulsed mass of shining, glancing, silvery scales, one compact crowd of thousands of fish, each one of which is madly endeavouring to escape, appears in an instant. The noise before was as nothing compared with the noise now. Boats as large as barges are pulled up in hot haste all round the net; baskets are produced by dozens: the fish are dipped up in them, and shot out, like coals out of a sack, into the boats. Ere long the men are up to their ankles in pilchards; they jump upon the rowing benches, and work on, until the boats are filled with fish as full as they can hold, and the gunwales are within two or three inches of the water. Even yet the shoal is not exhausted; the 'tuck' net must be let down again and left ready for a fresh haul, while the boats are slowly propelled to the shore, where we must join them without delay.

"As soon as the fish are brought to land, one set of men, bearing capacious wooden shovels, jump in among them, and another set bring large hand-barrows close to the side of the boat, into which the pilchards are thrown with amazing rapidity. This operation proceeds without ceasing for a moment. As soon as one barrow is ready to be carried to the salting-house, another is waiting to be filled. When this labour is performed by night, which is often the case, the scene becomes doubly picturesque. The men with the shovels, standing up to their knees in pilchards, working energetically; the crowd stretching down from the salting-house across the beach, and hemming in the boat all round; the uninterrupted succession of men hurrying backwards and forwards with their barrows through a narrow way, kept clear for them in the throng; the glare of the lanterns giving light to the workmen, and throwing red flashes on the fish as they fly incessantly from the shovels over the side of the boat, all combine together to produce such a series of striking contrasts, such a moving picture of bustle and animation as no attentive spectator can ever forget."[1]

The fish are then carried to the curing-house, on the floor of which they are laid, with alternate layers of salt. There they remain "in bulk" for five or six weeks, during which time a quantity of oil, salt, and water, drips from them into wells perforated in the centre of the stone floor on which they lie. When taken out of "bulk," they are washed clean in salt water, and packed in hogsheads, which are shipped to Penzance, and other places, for exportation.

[1] *Rambles beyond Railways, or Notes in Cornwall taken a-foot.* By W. Wilkie Collins. P. 148.

Mackerel-fishery.

The trade is chiefly to the shores of the Mediterranean—Italy and Spain being the great foreign markets. The home consumption is next to nothing. Of course the value varies, but the average wholesale price may be stated at about 50s. per hogshead. The general export is about 22,000 hogsheads. The quantity sometimes taken is almost incredible. As many as 2200 hogsheads have been secured in a single seine, and Borlase mentions even 3000 as the result of a single capture. The number of pilchards to a hogshead was formerly 3500, it afterwards fell to 3000, and has since been reduced to about 2500, although they are not individually counted. According to Mr Yarrell, an instance has been known of 10,000 hogsheads being taken ashore at one spot in a single day, thus providing the enormous multitude of twenty millions of living creatures drawn almost at once from the briny deep for the sustenance of man.[1]

We know not the present value or importance of the pilchard-fishery, but so far back as 1827, when the bounty began to be withdrawn, the conditions were as follows:—number of seines employed, 186; not employed, 130; total number of seines, 316; number of drift boats, 368; men employed on board drift-boats, 1600; number of men employed on seines at sea, 2672; number of persons on shore to whom the fishery affords direct employment, 6350; total number of persons employed in the fishery, 10,521; cost of seines, boats, &c., used in the fishery, L.209,840; cost of drift-boats and nets, L.61,400; cost of cellars for curing, and other establishments on shore for carrying on the fishery, L.169,175; total capital invested directly in the pilchard-fishery, L.441,215. The outfit of a seine amounts to about L.800. A string of drift-nets will cost about L.6; the net and the boat from L.100 to L.150; but these are used throughout the year for the other purposes of fishing.[2]

Although white bait, sprats, shads, and others, belonging to the herring family (*Clupeidæ*), should here be mentioned as of some importance in our fisheries, we must pass them over without any detailed notice, in consequence of our want of space.

The mackerel (*Scomber scomber*), though long regarded as a migratory fish, may be taken, like the herring, on some part of our coast, during every month throughout the year. Those got in the months of May and June are considered to be in higher condition than such as are brought to table either in autumn or early spring. Of all fishes, they deteriorate the most rapidly after death, and so, to be eaten in perfection, they ought to be consumed as soon as caught. Mackerel were first allowed to be cried through the streets of London on a Sunday in the year 1698, and the practice has continued ever since. It seems the habit of this fish to present itself ever and anon in the most extraordinary quantities, and the greater the pity that it should so speedily lose its natural flavour. "Mackerel," says Mr Yarrel, "were so plentiful at Dover in 1808, that they were sold at sixty for a shilling. At Brighton, in June of the same year, the shoal of mackerel was so great, that one of the boats had the meshes of her nets so completely occupied by them, that it was impossible to drag them in; the fish and nets, therefore, in the end sunk together, the fishermen thereby sustaining a loss of nearly L.60, exclusive of what the cargo, could it have been got into the boat, would have produced. The success of the fishing in 1821 was beyond all precedent. The value of the catch of sixteen boats from Lowestoffe, on the 30th June, amounted to L.5252; and it is supposed that there was no less an amount than L.14,000 altogether realized by the owners and men concerned in the fishing of the Suffolk coast.[3] In March 1833, on a Sunday, four Hastings boats brought on shore 10,800 mackerel, and the next day two boats brought 7000 fish. Early in the month of February 1834, one boat's crew from Hastings cleared L.100 by the fish caught in one night."[4] This was an earlier appearance than usual. During the last-named year a large quantity of fine mackerel were shown in the London markets in the second week of February. They were cried through the streets of the metropolis, three for a shilling, in the middle of March, and had then been plentiful for a month.

The usual mode of fishing for mackerel is by a drift-net 120 feet long and 20 feet deep. It is corked at the top, but has no leads below. It is made of fine twine, the size of the mesh being about two inches and a half, or rather more. From twelve to eighteen of these nets are attached to each other lengthways, by being tied along a thick rope called the drift-rope. When arranged for setting, a large buoy attached to the end of the drift-rope is cast into the sea, the vessel is put before the wind, and, as she makes way, the rope with the nets attached is passed over the stern, till the whole is run out. The drift-rope is then shifted from the stern to the bow of the vessel, after which she rides as if at anchor, while, at the sametime, the conjoined nets, sometimes a mile and a half long, are thereby kept strained, or in a straight line. When a large shoal, or *schul*, as it is called in Cornwall—

> "In sculls that oft
> Bank the mid sea,"

says Milton—shows itself, the congregation is encompassed by a small meshed seine-net, after the pilchard mode already mentioned, and are lifted on board the boats in flaskets. Sometimes the whole mass is hauled bodily ashore upon the beach. As mackerel will bite at almost any bait, quantities are likewise killed by hook and line. A slice cut from the side of one of themselves, near the tail, is a successful lure for its quondam companions, and even a slip of red leather or scarlet cloth, will slay its hundreds. The boat is kept in progress under sail, and a fresh breeze is advantageous.

Cod-fishery.

We shall now devote a few columns to the consideration of the cod-fishery. Although it might be supposed that, amid the exhaustless resources of the almost illimitable sea, the production of the finny tribes would not be greatly influenced by the actions of the human race, there seems to be no doubt that constant fishing tells upon these tribes to a certain extent, just as it is known to do more largely on those of narrower waters. By the statements of fishermen in general, it appears that the boats are almost everywhere obliged to go farther from the land than formerly before they find fish; and it is hence assumed, either that these have changed their ground, or that the places near the shore have been to a certain extent exhausted by over-work.[5] Of this there is no doubt, that much longer voyages are now undertaken in connection with the cod-fisheries than of old. Expeditions of smacks and other vessels to Davis' Straits to fish for cod, have been set agoing of late years, with various success. English smacks have made trips to Iceland, landing their fish, as they brought them home, at Stornoway in Lewis. Some were kept alive in wells of the smacks, but the greater part were salted. From

---

[1] Pennant, while referring to the great capture of pilchards recorded by Borlase, has committed the extraordinary mistake of reckoning 35,000 fish to a hogshead, instead of 3500.

[2] Yarrell's *British Fishes*, vol. ii., p. 105.

[3] Messrs C. and J. Paget, in their *Natural History of Yarmouth and its Neighbourhood*, state that, in 1823, 142 lasts of mackerel were taken there. A last is 10,000. This makes 1,422,000 individuals.

[4] *British Fishes*, vol. i., p. 126.

[5] Sometimes local changes of a contrary kind occur. Thus, Mr Yarrell (writing about 1837) informs us that formerly the Gravesend and Barking fishermen captured no cod nearer than the Orkneys or the Dogger Bank, but that "for the last two or three years the supply for the London market has been obtained by going no farther than the Lincolnshire and Norfolk coasts, and even between that and London, where previously very few fish could be obtained."—*British Fishes*, vol. ii., p. 147.

Cod-fishery.

two smacks alone 27,000 cod-fish were landed. This cod-fishing off the Icelandic shores has long drawn the attention of the French, and has been actively and successfully prosecuted by them. There seems no reason why the British should not be at least equally adventurous in the same quarter. Vessels sailed from Shetland for the Faroe Isles in 1851, and one of these returned with as much cod and ling as when dried weighed thirty tons. Our cod and ling fisheries may be said to be of a much more stationary character than that for herrings. Though the value may be sometimes suddenly affected by the occasionally great success of the far northern captures just referred to, the annual yield of our own coasts seems very uniform.

It has been bountifully ordained, that while fish of the herring family usually most abound in summer and autumn, those of the *Gadidæ*, including cod, haddock, whiting, and several others, all more or less remarkable for the excellence of their flesh, are in best condition during the colder season of the year. The common cod (*Morrhua vulgaris*) is of the highest intrinsic value, and is providentially spread over a great expanse of the European seas, from Iceland almost to Gibraltar. It does not enter the Mediterranean, but all along the eastern shores of North America and its islands, from the 40th to the 66th degree, the supply is countless and inexhaustible. It is fortunately a fish of great voracity, and so is easily taken with a variety of baits. The usual mode of capture is by long deep-sea lines, with hooks fastened at regular distances along their whole length by shorter cords called snoods. The latter are six feet long, and are placed about twelve feet apart. Of course variations occur in the practice of particular places. Buoys and small anchors are fixed to each end of the line, which is shot across the run of the tide. An improvement was suggested many years ago by Mr Cobb, who was sent to Shetland by the commissioners of the fisheries. He attached a small piece of cork within about a foot of the hook. This suspended the bait, and prevented its lying concealed from the fishes' view by the inequalities of the ground, and also kept it more clear from the attacks of crabs and star-fish. A deal of hand-line fishing is also practised for cod, haddock, and and other white fish. Each fisherman has two lines armed with a pair of hooks, kept apart by a piece of wire or whalebone, and *leaded* so as to keep the bait near the ground. Cod inhabit deep water, and are usually fished for in from 25 to 40 or 50 fathom. Many cargoes are kept alive in welled-smacks, and are carried from great distances to the vicinity of the metropolitan markets. We once took occasion to visit one of those vessels at Stromness in Orkney. She was sloop-rigged—a capital sea-boat—went extremely fast—and measured 62 tons, old register. The skipper said he thought he would have no chance with a good yacht in light winds, but that in heavy weather he would keep a fair place with anything. The well was immediately abaft the mast, boarded off from the rest of the vessel, and communicating with, and receiving its water directly from, the sea beneath, by means of numerous perforations in the bottom of about two inches in diameter. Its length backwards from the mast seemed about ten or twelve feet, and its breadth nearly that of the sloop itself. The well was capable of holding about fifty score of live cod, and there were about ten score in it at the period of our examination. They seemed rather softened and subdued by their captivity, and came ever and anon with a lazy heave to the surface, showing their great flat heads, dim unexpressive eyes, and gaping mouths. Though heavy and stupid in their aspect, they seemed to have their senses about them, and speedily seized upon and swallowed such portions of shell-fish as we dropped into their watery chamber. To produce perpetual change in the waters of the well, these vessels are usually either anchored in a tideway, or one of the sails is kept partially set, so as to produce a constant heaving motion, and a consequent circulation of the briny flood. The fish are often confined in this way for a fortnight or three weeks, and if they show any symptoms of sickliness, the usual medical routine is reversed in their case,—they are killed first and cured afterwards. These sloops venture with their cargoes no farther up the Thames than Gravesend, beyond which the influence of the intermingling fresh water would prove destructive. From that point they are conveyed to market in boats with closed wells filled with sea-water. During all this lengthened period of confinement they seldom give them any food, although those we saw seemed well inclined to eat, from the rapid voracity with which they gobbled up our limpets.

Cod-fishery.

Although the deep-sea and hand-line fishing are thus of importance in affording to the fish-eating public a salubrious supply in firm and fresh condition, it is the quantity of cured cod and other allied kinds which constitutes their chief mercantile importance.

Abstract of the Total Quantity of Cod, Ling, or Hake, Cured and Exported, in so far as the same have been brought under the cognizance of the Officers of the Fishery, *from the* 10*th October* 1820, *when the system hitherto in force for the encouragement and improvement of the Cod and Ling Fishery took place, to the* 31st *December* 1854, *distinguishing each Year as under. From* 1822 *to* 1844 *inclusive, the periods are calculated as from* 10*th October to* 5*th April. They then run from* 5*th April to* 5*th January, up to* 1852 *inclusive. From* 5*th January* 1851 *and onwards, the quantities noted are for Scotland and the Isle of Man only.*

N.B.—The books of the Board of Fisheries do not exhibit the total quantity of cod, ling, or hake *cured* till the year commencing 5th April 1825. The bounty, from the commencement of this Abstract to the 5th of April 1830, was 4s. per cwt. for fish cured dried, and 2s. 6d. per barrel for fish cured in pickle, taken by the crews of vessels or boats *not* on the tonnage bounty; while the bounty for vessels licensed for the cod and ling fishery, or the *tonnage* bounty, was 50s. per ton, for tonnage and cargo to the 5th of July 1826; 45s. from thence to the 5th of July 1827; 40s. to the 5th of July 1828; and 35s. to the 5th of April 1830, when the bounties ceased altogether, and have not since been renewed.

Stornoway, and the Orkney and Shetland Islands, are the principal stations for these fish. Thus, of the 109,684 cwt. taken at the twenty-one stations of which our cod districts consist, 73,707 cwt. belonged to the three localities just named. The quantity of individual fish of the cod and ling kind killed in 1854 was 3,523,269, of which 1,385,699 were from the Shetland Islands. The great exports of dried fish

[1] For the year ended 5th January.

[2] For the year ended 31st December, and so also for the two subsequent years.

Cod-fishery.

are also from these islands. Thus, there were last year exported to Ireland 7855 cwt., and to continental Europe 5630 cwt., making 13,485 cwt. out of 19,557, the entire quantity exported. Besides these weights of cured fish, there was 58,042 cwt. disposed of fresh, making a grand total of 167,726 cwt., cured or fresh, and 6166 barrels preserved in pickle.

The following is the mode of curing dried cod, &c., practised in our northern isles. The fish are generally gutted before they are brought ashore. As soon as they are landed, the *splitter* with a large knife cuts them open from head to tail, and extracts the upper half of the back-bone. He then hands them over to the *washer*, who, with a brush and sea-water, cleanses them of every particle of blood. When all the fish have been in this way split and washed, they are allowed to drain, and then come into the hands of the *salter*, who places a stratum of salt at the bottom of a large wooden vat, and over it a stratum of fish, and so on alternately till the vat is filled. Above all are laid heavy stones to keep the fish beneath the pickle. After the lapse of some days they are taken out, well washed, and brushed from shoulder to tail, and put up in small heaps, called *clamps*, to drain. They are then spread upon the shingly beach slantingly, with the back undermost, exposed to the action of the sun and air; and after being thus alternately clamped and exposed singly, they are built into larger stacks, called steeples, which, for the sake of equal pressure, are themselves occasionally taken down and rebuilt, by which means the fish that were uppermost at one time, are undermost at another. As soon as this drying, or pining, as it is technically called, is completed (as indicated by a white efflorescence appearing on the surface, named the bloom), the fish are transported to a dry cellar lined with wood, and piled up closely, if not speedily shipped off to market.[1] We may add, that the Yorkshire curers, who are thought the best in the world, dry their fish on wooden flakes, raised on posts three feet high, of such length as may be requisite, and about four feet wide. There is a platform of cross bars at the top, placed six inches asunder, on which the fish are laid. The great advantage of this method is, that it preserves the fish perfectly clean, while, owing to the current of air passing underneath, the process of drying goes on as rapidly below as above. It also prevents the fish being sunburnt, blistered, or scalded, when first laid out, as not unfrequently happens if they are suddenly placed upon a stony beach in a hot day. When nothing but the beach is available, great care should be taken not to lay the fish out, for the first time, when the stones are too warm. Fish prepared for the Spanish market (where they are in great demand) ought to be rather lightly salted, of a pure greenish colour and transparent aspect, and very hard dried.

As the greatest cod-fishery in the world is carried on over the banks of Newfoundland, we shall here give a sketch of the *modus operandi*, as from a recent eye witness. The fish are all caught with hooks, and, as usual, from the bottom. Each fisherman has a strong line of from 60 to 70 fathoms in length, to which is attached a lead of a cylindrical shape, weighing about five pounds. From this proceeds the "pennant," which is a cord about twice the size of the line, and three feet in length. To the lower end of the pennant, and attached to it by a small copper swivel, is the "craft," which is a stout cord about 2½ feet in length, having three strips of whalebone laid around it at the middle, where it is attached to the swivel of the pennant. The whole is then serried or wound round with tarred twine. On each end of the craft is a smaller swivel, into which the gauging of the hooks is attached. The whalebone serves to keep the hooks about a foot apart, so there is little danger of their becoming entangled with each other.

Other sea-fisheries.

The men arrange themselves on the windward side of the deck, throw over their leads, and unreel their lines, till the lead rests on the bottom. It is then drawn up, so that the hook will touch the bottom with the down pitch of the vessel. They lean over the bulwarks, patiently awaiting a bite, which is known by a slight jerk on the line. They then give a sudden pull, in order to hook the fish, stand back, and haul in the long line, hand over hand, until the fish comes up to the surface, when he is taken on deck, unhooked, and thrown into a square box, which each man has fastened by his side, called a "kid." The hooks are then baited and hove over again, and the fisherman, while the line is running, picks up the fish caught and cuts out his tongue.

Towards night the fish are counted out from the kids, each one separately, and thrown into a large kid near the main hatch, called the "dressing kid." They are counted aloud as they are thrown along, and each man is required to keep his own account, and report to the skipper at night, who keeps a separate account for each man on the log-book. The dressing-gang, consisting of a "throater," a "header," a "splitter," and a "salter," now commence dressing down. After passing through the hands of the first three, they assume somewhat the shape seen in market. They are then passed down between decks to the salter, who puts them up in kenches or layers, laying the first tier on the bottom of the hold, and building up with alternate layers of salt and fish till the kench reaches the desired height. The decks are then washed down, sails taken in, and the vessel anchored for the night.[2]

The haddock (*Morrhua æglefinus*) now deserves a brief notice. This fish is of great value, from its excellence and frequency combined. It may be traced everywhere along the coasts of Great Britain and Ireland, the largest and finest being taken in Dublin Bay, and off the Nymph Bank. The haddock is extremely abundant on our eastern English shores from Yarmouth to the Tyne, and occurs plentifully on the same side of Scotland. This fish does not exist either in the Baltic or Mediterranean. It swims in great shoals, and not unfrequently shifts its stations, probably from the necessity of a change consequent on the consumption of food. The mode of capture is with long lines and hand-lines; and where the trawl-net is in use for other fish, the haddock, which, like the majority of the bearded fishes, feeds near the ground, is frequently taken by the trawl.

In the north-east of Scotland many people prepare these fish, not only for their own use, but also for sales, to a very large amount, at their own firesides, by appropriating a space in their chimneys, where the heat and smoke are applied without in any way interfering with the other domestic arrangements; and in those districts where wood is not to be had, peat or turf is used, and answers every purpose.

The fish, when freed from the head and intestines, is split, washed, and thoroughly cleaned from all impurities. It is then put in salt from one hour to five, and smoked and dried from six hours to twelve, the degrees of salting and smoking being modified according to the size and thickness of the fish, and the length of time it may be required to preserve it for consumption. At Findon in Aberdeenshire, from whence the "Finnans" derive their name, the fishermen use nothing but turf in the smoking process. Three hundred fish can be prepared at an ordinary-sized domestic fireside at one time. The split fish are hung from timber rods, which are passed across their upper or widest

[1] See Hibbert's *Shetland Islands*, p. 519, and Wilson's *Voyage round Scotland*, vol. ii., p. 331.
[2] See Hunt's *Merchants' Magazine* for March 1855.

Other sea-fisheries.

part, so as to keep them extended; these rods are then placed across the space from the wall to the chimney-piece at either side of the hearth, and small quantities of damp turf being lighted beneath, the smoke performs its office by ascending the chimney. For a near market, where the fish are likely to be consumed in about four or five days, half an hour in salt or pickle, and four to six hours' smoking will be sufficient. To supply the markets not only of Aberdeen, but even of the great southern cities, great quantities of this description of fish are now prepared and sent off from many other northern villages besides Findon. The degree of cure is regulated by the time which must elapse before the article can be used, an additional half-hour or more in salt, and two or more hours longer smoking, being given if required. Attention is paid to the state of the weather, the distance from markets, and the taste of the consumers.

The commerce in this description of fish has greatly increased in Scotland, many having embarked in it on a large scale by erecting extensive curing-houses, and purchasing haddocks from numerous captors, who confine themselves almost solely to this department of fishing. The whole process, when performed upon the smaller scale, and by the country people, takes only a few hours; so that fish caught in the evening may be in a market many miles distant on the morning of the following day. The real Finnans are generally small, and of a pleasant pale yellow colour; but larger fish are cured at the great commercial stations, and in a way intended to admit of their being sent a longer distance, and keeping for a longer time.

The whiting (*Merlangus vulgaris*) is regarded by many competent judges as the most delicate fish of this family. It occurs around our coasts, and advances pretty far northwards from the Orkneys to Cape Clear. Large examples are caught upon the Dogger Bank,[1] as well as on the coast of Cornwall, and the southern and other shores of Ireland. The whiting is fished for with lines; and although taken almost all the year through, it is most abundant in mid-winter, by which time it makes its approaches to the spawning places, at no great distance from the shore, and may then be taken in larger quantities than usual, within from half a mile to three miles from shore.

The coal-fish (*Merlangus carbonarius*) is a larger and coarser species, which is spread far northwards, being well known off Spitzbergen and in Davis' Straits. It enters the Baltic Sea, and is very abundant in Scotland and among our western and northern isles, where the fry, fished for from the rocks, often afford good sustenance to the poorer classes. It rejoices in many names, being in its different stages and districts known as silloch, podley, cuddy, sethe, coal-fish, and gray-lord. It attains to a weight of from fifteen to thirty pounds, and is often salted, and cured dry—bringing, however, a lower price than its congeners.

The hake (*Merlucius vulgaris*) is another of the coarser kind, caught like the preceding by hook and line. It is less abundant in Scotland than along some of the southern shores of England. Portsmouth is largely supplied from the Devonshire coast. Mr Couch describes it as roving about the Cornish shores in a somewhat irregular way, and as being extremely voracious in its habits. It is often inclosed in the circle of the seine-net, along with the pilchards, and being sometimes left undisturbed for several days it gluts itself to its heart's content. Seventeen of these fish have been taken from the interior of a hake of ordinary size. It occurs around Ireland, and is so abundant in the Bay of Galway as to have given the name to that district, as marked in some ancient maps, of the *Bay of Hakes*. In the salted state it is exported to Spain, although itself common on the northern shore of the Mediterranean, where it affords considerable traffic, being packed up in aromatic plants, and transmitted to the towns of the interior.

The ling (*Lotus mola*) is a much finer fish. Large quantities are taken by hook and line from Cornwall and the Scilly Isles to Shetland. It is excellent when cured, is much used for home consumption, and is pretty largely exported to Spain.

The tusk (*Brosmius vulgaris*) is another highly-esteemed species. It is one of the best in the cured state, swelling out well when boiled, and separating into thick firm flakes. It is a northern fish, frequent in the Orkneys, and abundant in Shetland. According to Faber (to whom we owe so much information regarding northern species), it seems to possess less power of resisting the violence of the sea than the majority of fishes, as it is sometimes dashed ashore dead in incredible numbers on the coasts of the Faroe Islands and the south of Iceland. He adds that, "Jan Olsen" says, that the fresh fish is badly tasted, but when dried is the best of food. We have not the pleasure of being acquainted with Jan Olsen, but the former portion of his opinion is most erroneous, and must be corrected. Fresh tusk is one of the very best of all fishes, either in or out of the sea, and it is worth any man's while to make a voyage to the Shetland Isles (in themselves so interesting), for no other purpose than to eat it. Jan is really very wrong.

A few words must suffice for flat-fish. Of these we have in this country at least sixteen different kinds, the majority in good request as food. Plaice, flounders, dabs, &c., may pass without any special notice. The largest of all the flat-fish, or *Pleuronectidæ*, is the holibut (*Hippoglossus vulgaris*), a species which sometimes weighs from 300 to 500 pounds. It is a northern fish well known in Greenland, not unfrequent in the Scotch markets, but rarer as we proceed southwards.

Of smaller size, but far more delicate flavour, is the true turbot (*Rhombus maximus*), the finest of the flat fishes. Its localities are much more southern than those of the preceding. It is caught both by the long line system already described, and by trawling. The English markets are largely supplied from the various sand-banks which lie between our eastern coasts and Holland. The Dutch turbot fishery begins about the end of March, a few leagues to the south of Scheveling. The fish proceed northwards as the season advances, and in April and May are found in great shoals upon the banks called the Broad Forties. Early in June they surround the island of Heligoland, where the fishery continues to the middle of August, and then terminates for the year. At the beginning of the season the trawl-net is chiefly used, but on the occurrence of warm weather the fish retire to deeper water, and to banks of rougher ground, where the long line becomes indispensable. Although a considerable quantity of turbot is taken on various parts of our own coasts, a preference is said to be given in the London markets to those caught by the Dutch. According to a calculation made some years ago (in the preceding edition of this Encyclopædia), that nation was supposed to draw not less than L.80,000 a-year for the supply of our metropolitan market alone; while the Danes (to whom the outer shores of Scandinavia formerly pertained)

[1] As bearing upon the general character and condition of this famous bank, we make the following extract from an amusing and instructive article on the "London Commissariat," in the *Quarterly Review*. "No better proof that its stores are failing could be given than the fact that, although the ground, counting the Long Bank and the north-west flat in its vicinity, covers 11,800 square miles, and that in fine weather it is fished by the London companies with from fifteen to twenty dozen of long lines, extending to ten or twelve miles, and containing from 9000 to 12,000 hooks, it is yet not at all common to receive even as many as four score fish of a night, a poverty which can be better appreciated when we learn that 600 fish for 800 hooks is the catch for deep-sea fishing about Kinsale." No. CXC., p. 280, September 1854.

Other sea-fisheries.

Other sea-fisheries.

charged us from L.12,000 to L.14,000 a-year for sauce, made from one million of lobsters exported from the rocky shores of Norway. Mr Yarrell informs us that about one-fourth of the whole supply of London turbot is furnished by the Dutch. There is good trawling, as well as long-line fishing for this highly-prized species, over two extensive sand-banks called the Varne and the Bridge—the one about seven, and the other about twelve miles from Dover, towards the French coast. Trawling for turbot is also extensively practised along the coast of Devonshire, from which supplies are sent to Bath and Exeter, as well as London.

The sole (*Solea vulgaris*), though a much smaller, is a highly esteemed species. It inhabits sandy shores around the coasts of both Britain and Ireland. Those of our south and west districts are of larger size and finer quality than such as occur off the north and east stations. Soles seldom take a bait, but are caught in enormous quantities by means of the beam-trawl. The principal grounds lie along the south coast from Sussex to Devonshire. Two very productive stations are Brixham and Torbay.

Although skate, eels, and several other fishes of some value, remain unnamed, we must here close a treatise which has extended to a greater length than was foreseen at its commencement. The importance of the general subject, and the multiplicity of its departments, must plead our excuse. We shall conclude with a brief extract, and one more tabular view.

"Next to the herring-fishery," says the writer already referred to, "the sea-harvest of most importance to the poor of London is that of sprats, which come in about Lord Mayor's day, and it is a popular belief that the first dish is always sent to the chief magistrate of the city. The plaice season succeeds that of sprats, with the interval of mackerel, which continues until the end of May, when Scotland and Ireland pass their salmon into the market. But where do all the lobsters come from? The lovers of this most delicious of the crustacean tribe will probably be astonished to learn, that they are mainly brought from Norway, France, and the Channel Islands. Orkney and Shetland do, it is true, contribute a few to the metropolitan market; but full two-thirds are reluctantly, and with much pinching and twisting, dragged out of the thousand rock-bound inlets which indent the Norwegian coast. The fighting, twisting, blue-black masses are taken as soon as purchased to what are termed 'the boiling-houses,' of which there are four, situated in Duck and Love Lanes, close to the market, and here, for a trifling sum per score, they change their dark for scarlet uniforms. They are all plunged into the boiling cauldron, basket and all, and in twenty minutes they are done. Crabs are cooked in the same establishments, but their nervous systems are so acute, that they dash off their claws in convulsive agony, if placed alive in hot water. To prevent this mutilation, which would spoil their sale, they are first killed by the insertion of a needle through their head. The lobster trade is mostly in the hands of one salesman, Mr Saunders, of Thames Street, who often has upwards of 15,000 consigned to him of a morning, and who causes no less than L.15,000 a-year to flow into the fishy palms of Norwegians for this single article of commerce."[1]

The following table of the total supply of fish to the London market, is from Mr Mayhew's work on *London Labour and the London Poor.*

Description of Fish.	No. of Fish.	Weight of Fish. lb.
Wet Fish.		
Salmon and salmon-trout (29,000 boxes, 14 fish per box)	406,000	3,480,000
Live cod (averaging 10 lb. each)	400,000	4,000,000
Soles (averaging ¼ lb. each)	97,520,000	26,880,000
Whiting (averaging 6 oz. each)	17,920,000	6,720,000
Haddock (averaging 2 lb. each)	2,470,000	5,040,000
Plaice (averaging 1 lb. each)	33,600,000	33,600,000
Mackerel (averaging 1 lb. each)	23,520,000	23,520,000
Fresh herrings (250,000 barrels, 700 fish per barrel)	175,000,000	42,000,000
Ditto in bulk	1,050,000,000[2]	252,000,000
Sprats	...	4,000,000
Eels from Holland (principally), England and Ireland (6 fish per lb)	9,797,760	1,505,280 127,680
Flounders (7200 quarterns, 36 fish per qtn.	259,200	43,200
Dabs (7500 quarterns, 36 fish per qtn.)	270,000	48,750
Dry Fish.		
Barrelled cod (15,000, 40 fish per barrel)	750,000	4,200,000
Dried salt cod (5 lb. each)	1,600,000	8,000,000
Smoked haddock (65,000 barrels, 300 fish per barrel)	19,500,000	10,920,000
Bloaters (265,000 baskets, 150 fish per basket)	147,000,000	10,600,000
Red herrings (100,000 barrels, 500 fish per barrel)	50,000,000	14,000,000
Dried sprats (9600 large bundles, 30 fish per bundle)[3]	288,000	96,000
Shell Fish.		
Oysters	495,896,000	...
Lobsters (averaging 1 lb. each)	1,200,000	1,200,000
Crabs (averaging 1 lb. each)	600,000	600,000
Shrimps (324 to a pint)	498,428,648	...
Whelks (227 to half bushel)	4,943,200	...
Mussels (1000 to half bushel)	50,400,000	...
Cockles (2000 to half bushel)	67,392,000	...
Periwinkles (4000 to half bushel)	304,000,000	...

(J. W.)

[1] *Quarterly Review* for September 1854, p. 280.

[2] We feel somewhat doubtful in regard to this enormous aggregate. It will be seen from our preceding exposition of the herring-fishery, that the entire recorded take for the whole of Britain (including the fish consumed fresh, cured in salt, and smoked as *reds*), amounted in 1849 to 1,151,979 barrels. This, allowing 800 to a barrel, would give *nine hundred million* of individual herrings, with above *twenty-one million* over. Now the quantities in the above table (including both barrels and bulk) would seem to show that the London market alone, and supplied chiefly from Yarmouth, receives an annual stock of fresh herrings amounting to *twelve hundred million* of individuals, with *twenty-five million* over. We have applied to the Board of Fisheries for the English returns for 1849, of herrings disposed of fresh, and find as follows:

	Barrels.		Barrels.
Bristol	3,500	North Sunderland	21,400
Isle of Man	10,000	Whitby	29,123
Liverpool	17,600	Yarmouth	113,574
St Ives	1,800		
Whitehaven	12,790	Making a total for the south country of	236,011
London	26,224		

This, at the rate of 800 to a barrel, gives only *one hundred and eighty-nine millions* of individuals, with above *two hundred thousand* over. Of these a considerable number (probably the majority of such as were caught upon the western coasts) would be consumed elsewhere than in London. We know not how much of the Yarmouth herrings "in bulk" may have been transported rapidly, and without record, but upon the whole we apprehend some exaggeration or mis-statement in the matter.

We desire in this place to express our obligations to the Hon. B. F. Primrose, secretary to the Board of Fisheries, and his assistants in office, for the readiness with which he and they have at all times aided us in our researches.

[3] We may note as follows (from the *Return of the quantity of fish sold at Billingsgate in* 1850) regarding certain species omitted from the above:—Turbot (from 2 to 16 lb. each) 2500 tons, or 800,000 fish. Brill and Mullet (3 lb. each) 1500 tons, or 1,220,000 fish.

Pearl Fishery. See Mollusca, § *Pearls;* and Pearl.

Whale Fishery. See *Balæna*, index to Mammalia.

FISHGUARD, a seaport-town of South Wales, county of Pembroke, 14 miles N. of Haverfordwest. It is called by the natives *Abergwaen*, from its situation at the mouth of the little river Gwaen, over which there is a good stone bridge. The town is small and ill-built, and in the older part of it the street is so ill constructed as to be extremely inconvenient for the passing of carriages. The harbour is capacious, and at all times easy of access, being unobstructed by shoals or bars, and sheltered by the bold promontories of Dinas Head and Penainglas. The bay extends from E. to W. about 3 miles, and from N. to S. more than a mile and a half. Its general depth is from 30 to 70 feet, and ships of the largest size may anchor in all parts of it with perfect security. The trade, however, is unimportant. About 2½ miles S. of the town a French force of 1400 men, under General Tate, landed on 22d February 1797, and next day surrendered to a few militia and volunteers not half their own number. Fishguard unites with Haverfordwest and Narberth in returning a member to parliament. Pop. (1851) 1757.

FISHING. See Angling, and Fisheries.

FISSIROSTRES. See index to Ornithology.

FISTULA was used by the Romans to denote any small pipe, a reed, &c.; and more particularly the shepherd's or Pan's pipe, which was a combination of reeds gradually decreasing in length and calibre, corresponding to the syrinx of the Greeks.

Fistula, in *Surgery*, a deep, narrow, and callous ulcer, arising generally from abscesses. It differs from a *sinus* in being callous, which the latter is not.

FITCH, a chick-pea, a vetch. See Agriculture, vol. ii., p. 328–9.

FITCHY, in *Heraldry* (from the French *fiché*, fixed), a term applied to a cross when the lower branch ends in a sharp point. The origin of this device is supposed to be, that the primitive Christians were accustomed to carry about crosses with them, and when they stopped at any place on a journey they fixed these portable crosses in the ground for the purposes of devotion.

FITZ, the old French word for *fils*, a son, and which, as a prefix to proper names, corresponds to the Celtic *Mac*, to the Hebrew *Ben*, and its Aramaic synonym *Bar*.

FITZHERBERT, Sir Anthony, a distinguished lawyer in the reign of Henry VIII., was born at Norbury in Derbyshire, but in what year is not known. He was educated at Oxford, passed rapidly through the lower grades of the legal profession, and in 1523 was made a puisne judge of the court of common pleas, an office which he held till his death in 1538.

Fitzherbert's works are—The Grand Abridgment collected by that most reverend judge Mr Anthony Fitzherbert, lately conferred with his own manuscript corrected by himself, together with the references of the cases to the book, by which they may be easily found, printed in folio by Pynson in 1514, by Wynken de Worde in 1516, and again in 1577; The Office and Authority of Justices of Peace, 1538, but often reprinted, the last edition being dated 1617; The Office of Sheriffs, Bailiffs of Liberties, Escheators, Constables, Coroners, and others, 1538; Of the Diversity of Courts, 1529; The New *Natura Brevium*, 1534, to which, in the last edition, published in 1794, 2 vols. 8vo, is added a commentary supposed to have been written by Chief-Justice Hale, with notes, references, and an enlarged index; Of the Surveying of Lands, 1539; The Book of Husbandry, 1534, reprinted several times in the reigns of Mary and Elizabeth. Of these works, five, in the order in which they are here enumerated, were, with the exception of part of the second, originally written in French.

FITZJAMES, James. See Berwick, Duke of.

FITZSTEPHEN, William, author of the earliest extant description of London, was of Norman extraction, but born in the English metropolis during the first half of the twelfth century. He became a monk of Canterbury, and filled various offices in the household of Thomas à Becket. When that prelate was murdered, Fitzstephen alone of his numerous clerks and attendants did not fly, but was an eyewitness of the whole transaction. His Description of London originally formed part of another work, entitled *The Life and Passion of Archbishop Becket.* Stow, in his *Survey of London*, has appended a translation of Fitzstephen's work; but the best edition of it is that of Dr Pegge, London, 1772. Fitzstephen in his work shows a considerable acquaintance with the best Latin authors, and even a certain knowledge of the Greek classics. He is believed to have died in 1190.

FIUME (Illyrian *Réka*, German *St Veit am Flaum*), a seaport-town of the Austrian dominions, formerly capital of the Hungarian district of Littorale, now of the palatinate of Fiume in Croatia. It is situated on the gulf of Quarnero, at the mouth of the Fiumara in the Adriatic, 38 miles S.E. of Trieste. It consists of an old and a new town, the former standing on a hill, and consisting of steep and narrow streets, with old and mean houses; the latter extending along the shore, and having wide, clean, and well-paved streets, and many handsome edifices. In the old town is a fine Roman arch, but so hemmed in by hovels as to be difficult of access. The church of St Veit is an elegant building, not unlike that of St Maria della Salute at Venice. The casino is a handsome edifice, containing coffee and ball rooms and a theatre. On an adjacent height stands the old castle of Tersat. Fiume has manufactures of linens, coarse woollens, leather, paper, sugar, rosoglio, wax, and earthenware. It has been a free port since 1722. Being the immediate outlet by sea for the produce of Hungary, it was early looked upon as a place of importance; and the emperor Charles VI. constructed a magnificent road, called *Carolina*, about 75 miles in length, between it and Carlstadt in Croatia, where the inland navigation, by means of the Culpa and the Save, terminates. In 1809 the *Luisen Strasse*, also leading from Fiume to Carlstadt, was opened, and is now the principal means of communication between those two places. Carlstadt communicates with the coast at Zeng by means of a third road, constructed by the emperor Joseph II., and hence called *Josephina.* Fiume, however, is not a place of extensive trade, being naturally much inferior to Trieste. The harbour is accessible only to vessels of small burden, large vessels being obliged to anchor about three miles from the shore. The chief exports are wheat, wine, tobacco, timber, rags, and hemp. Pop. 11,000.

FIXED AIR, carbonic acid gas. See Chemistry, vol. vi., p. 471, &c.

FIXITY, or Fixedness, in *Chemistry*, the opposite of volatility; or that property by which bodies resist dissipation by heat.

FIXMILLNER, Placidus, a learned German astronomer, was born at Achleuthen, near Linz in Austria, in 1721. In 1737 he entered the Benedictine monastery at Kremsmünster, where a few years later he was appointed professor of ecclesiastical law, an office which he held for forty years. His fame, however, rests chiefly on his astronomical learning. The abbot had caused an observatory to be erected in the monastery, and Fixmillner was appointed chief astronomer. When he first entered upon the duties of this appointment his acquaintance with astronomy was very defective; but by severe study and unremitting application he not only overcame the deficiencies of his early training, but even earned a very respectable place in the second rank of astronomical observers. The value of his observations on the planet Mercury was publicly acknowledged by Lalande. Fixmillner was also one of the first to determine the orbit of the planet Uranus. His principal astronomical works are his *Meridianus Speculæ Astronomicæ Cremifanensis*, 1766; *Decennium Astronomicum*,

1776. He likewise contributed a large number of papers to many of the scientific journals of his own and other countries. He died in 1791.

FLACCUS, Caius Valerius, a Roman poet, of whose personal history little is known. He was contemporary with Martial, who addressed one of his epigrams to him, in which he urges him to exchange literary for legal pursuits as more likely to lead to fortune. He seems to have been a native of Padua, though, from the names *Setinus Balbus* found appended to some MS. copies of his works, some writers have attempted to show that he was born at Setia in Latium. The time of his death is equally uncertain. From the somewhat vague sentence of Quinctilian "Multum in Valerio Flacco nuper amisimus," it may be inferred that he died about the year 88 A.D., while still a youth. Flaccus' only known work, the *Argonautica*, is rather imitated than translated from the Greek of Apollonius. Though it abounds in episodes and digressions, sometimes wearisome and amid which the action of the plot is altogether lost sight of, it nevertheless contains many passages of fine description and poetical sentiment; and it has been remarked that those parts of the work are best in which he disregards his original model and works out scenes and incidents of his own invention. His diction is pure, though strange words sometimes occur, and ordinary words are sometimes found with unusual meanings. The sense is likewise occasionally obscured by the useless display of erudition in which Flaccus delighted, by the frequency of remote allusion, and the employment of far-fetched and unnatural similes. Altogether, Flaccus is an author much more admired than read. He appears to have been wholly unknown to the scholars of the middle ages. His works were first brought to light by Poggio Bracciolini, who discovered a MS. copy of part of the work in 1416 in the monastery of St Gall. Of the numerous editions which have appeared since that date, the best is that of Peter Burman, Leyden, 1724. The *Argonautica* has been translated into English by Nicholas Whyte, 1565, under the title, "The story of Jason, how he gotte the golden fleece, and how he did begyle Media;" out of Laten into Englische; into Italian by Pindemonte, Verona, 1776; into German by Wunderlich, Erfurt, 1805; and into French by De Lamalle, Paris, 1811.

FLAG, an ensign or colours; a cloth on which are usually displayed certain devices, and attached to a staff. In the army, it signifies a small banner by which one regiment is distinguished from another; in the marine, a certain banner by which an admiral is distinguished from the other ships of his squadron, or by which the ships of one nation are distinguished from those of another.

In the British navy flags are either red, white, or blue, and are displayed from the top of the main-mast, fore-mast, or mizen-mast, according to the rank of the admiral. When the flag is displayed from the staff on the main-mast, the officer distinguished thereby is known to be an admiral; when from the fore-mast, a vice-admiral; and when from the mizen-mast, a rear-admiral.

The first flag in Great Britain is the royal standard, which is only displayed when the king or queen is on board the vessel; the second is that of the anchor of hope, which characterizes the lord high admiral, or lords commissioners of the admiralty; and the third is the union flag, in which the crosses of St George and St Andrew are blended together. This last is appropriated to the admiral of the fleet, who is the first naval officer under the lord high admiral.

The next flag after the union is that of the white squadron, at the main-mast head; and the last, which characterizes an admiral, is the blue, also at the main-mast head. For a vice-admiral, the first flag is red, the second white, and the third the blue, at the flag-staff on the fore-mast. The same order is observed with regard to rear-admirals, whose flags are displayed at the mizen-top-gallant-mast head. The lowest flag in our navy is accordingly the blue on the mizen-mast.

To lower or strike the Flag, in the navy, is to pull it down upon the cap, or to take it in, as a token of the respect due from all ships or fleets to those which are undeniably their superiors. To lower or strike the flag in an engagement is a sign of submission or surrender.

The method of leading a ship in triumph is to attach the flags to the shrouds, or the gallery in the hind part of the ship, letting them hang down towards the water, and to tow the vessels by the stern. Livy relates that this was the mode in which the Romans used the ships of Carthage.

To Heave out the Flag, is to display or put abroad the flag.

To Hang out the White Flag, is to ask quarter: or, when a vessel has arrived on a coast, it shows that it has no hostile intention, but comes to trade, or the like. The red flag is a sign of defiance and battle.

Flag Officers are those who command the several squadrons of a fleet; such as the admirals, vice-admirals, and rear-admirals. The flag-officers in our pay are the admiral, vice-admiral, and rear-admiral, of the white, red, and blue. See Navy, and Signals.

FLAGELLANTS, a sect of religious fanatics, one of the leading doctrines of whose creed was that by mortifying the flesh in every conceivable manner they propitiated the wrath and gained the favour of the Deity. The first recorded instances of self-flagellation are isolated cases which happened about the beginning of the fifth century of the Christian era. From this date the practice began to spread till the middle of the eleventh century, when, by the precepts and example of cardinal Peter Damian, it came to be regarded by many religious persons as a sort of duty. The custom was very warmly opposed by the more liberal minds among the clergy, but it continued to spread in despite of all opposition; and soon after the middle of the thirteenth century, the devotees of the system, no longer content to mortify themselves in private, began to do so in public, under the idea that they thus humiliated themselves more completely in the sight of God. Societies were now formed by which the doctrine of flagellation was promulgated throughout Europe; and the excesses into which they were frequently hurried by the ardour of their enthusiasm excited the astonishment even of their contemporaries. The originator and promoter of these fraternities was a monk of Perugia, Rainer by name. "About this time," says the monk of Padua in his chronicles of the year 1260, "when all Italy was filled with vice, the Perugians suddenly entered upon a course never before thought of, after them the Romans, and at length all Italy. The fear of Christ exerted upon the people so strong an influence, that men of noble and ignoble birth, old and young, traversed the streets of the city naked, yet without shame. Each carried a scourge in his hand with which he drew forth blood from his tortured body amid sighs and tears, singing at the same time penitential psalms, and entreating the compassion of the Deity. Both by day and night, and even in the coldest winters, by hundreds and thousands they wandered through cities and churches, streets and villages, with burning wax candles. Music was then silent, and the song of love echoed no more; nothing was heard but atoning lamentation. The most unfeeling could not refrain from tears; discordant parties were reconciled; usurers and robbers hastened to restore their unlawful gains; criminals before unsuspected came and confessed their crimes."

From Italy the Flagellants crossed into Germany, and visited Bavaria, Bohemia, Poland, and Alsatia, making many proselytes on the way. The princes and higher clergy, however, were little pleased with the fanatics, whose popularity lay chiefly with the lower orders. The public exposure of the person which this sect practised as a matter of duty offended good manners; their travelling in large

numbers afforded opportunities for every sort of tumult and sedition; and their extortion of alms was a severe tax upon the peaceful citizens. From the Continent they passed over into England, where they astonished the burghers of London and other cities by the severity of their discipline; but they were finally obliged to retire from Britain without having made a single convert. The purity of the early Flagellants was not long maintained by their successors; and at length, as immorality began to spread in many of the countries which they visited, they gradually fell into disfavour even with the people. At length their order was openly attacked by the celebrated Gerson; Pope Clement VII. thundered anathemas against them from the Vatican; and the officers of the Inquisition persecuted them with such severity that the sect at last disappeared altogether. An attempt made in Thuringia in 1414 by Conrad Schmidt to revive the order was suppressed by the trial and execution of that leader, and the more prominent among his followers.

FLAGEOLET, a wind-instrument of music, made of hard wood, and blown by a mouth-piece. Some flageolets are very small, and have a shrill piercing sound. Flageolets are of different sizes, and tuned to different keys, *e.g.* C, D, E flat, F, and G. There are also double-flageolets, capable of playing two parts, in which two flageolets are joined together, and sounded by the same mouth-piece.

FLAIL, an instrument for threshing corn, consisting of the hand-staff, or piece held in the thresher's hand; the swiple, or that part which strikes the corn; the caplins, strong leathern thongs which unite the hand-staff and swiple; and the middle-band, a leathern thong or fish-skin that ties the caplins together.

FLAMBEAU, a kind of torch made of thick wicks, covered with wax, and used in the streets at night, at illuminations, and in processions. Flambeaux usually consist of four wicks or branches, about an inch in thickness, and three feet long, made of coarse half-twisted hempen yarn; and these, being suspended by one end, are coated with white or yellow wax, which is poured over them from a ladle until the requisite thickness be obtained.

FLAMBOROUGH HEAD, a cape or promontory on the eastern coast of Yorkshire, five miles east of Burlington, and 215 from London. This was the *Fleamburg* of the Saxons; having, it is supposed, been so called from the lights made on it to direct the landing of Ina, who, in 547, joined his countrymen in these parts with a large reinforcement from Germany, and founded the kingdom of Northumberland. In the time of Edward the Confessor, Flamborough was one of the manors of Harold, earl of the West Saxons, afterwards king of England; but on his death the conqueror gave it to Hugh Lupus, who bestowed it on the monastery of Whitby. Remains of a Danish tower and fosse are still to be seen. The cliffs rise perpendicularly from 300 to 450 feet in height, and are composed of a rock of the chalk formation, containing numerous extensive caverns, and frequented by immense numbers of sea-fowl and wild pigeons. Many of the rocks are insulated, and of a pyramidal figure, soaring up to a vast height. The bases of most are solid, but in some instances they are pierced through and arched. In 1806 a lighthouse was erected here, having a revolving light 214 feet above the sea. N. Lat. 54. 7., E. Long. 0. 5. Flamborough is a small fishing village, with an ancient parish church, which contains a curious monumental inscription to the memory of Sir Marmaduke Constable.

FLAME. See Heat; Chemistry; Damps; Pyrotechny; Fire.

FLAMINGO. See index to Ornithology.

FLAMEN, in *Roman Antiquity*, the name of any priest consecrated to the service of some particular deity. Of the flamens the highest in point of rank were the Flamen Dialis, Flamen Martialis, and Flamen Quirinalis, who were always selected from among the patricians. When the number of flamens was raised from three to fifteen, those already mentioned were entitled *majores*, in contradistinction to the other twelve, who were called *minores*, and were chosen from the plebs. The flamens were held to be elected for life, but they might be compelled to resign office for neglect of duty, or on the occurrence of some ill-omened event during the performance of its functions. The official dress of the flamens was the *apex* or cap, surmounted with a piece of pointed olive-wood, round the base of which a lock of wool was twisted; the læna or mantle; and a laurel wreath.

The most honourable of all these priests was the Flamen Dialis, who, in virtue of his office, was entitled to a lictor, to a seat in the senate, to the toga prætexta, and to a curule chair. If a person in fetters took refuge in his house he was immediately loosed from his bonds; and if a criminal on his way to the scene of his punishment met him and threw himself at his feet he was respited for that day. To counterbalance these privileges, numerous restrictions were laid upon the Flamen Dialis. He was not allowed to leave the city for a single night; to ride or even touch a horse, a restriction which incapacitated him for the consulship; to swear an oath; to wear a ring, &c. The wife of the Dialis (who was not allowed to re-marry in the event of her death) was called Flaminica, and was obliged to assist her husband at the sacrifices and other religious duties which he performed. Some of the municipal towns in Italy had flamens as well as Rome. When it became customary to deify the emperors, flamens were appointed in all the provincial towns to superintend their worship.

FLAMINIA VIA, an ancient Roman road, constructed by C. Flaminius during his censorship, 220 B.C. Proceeding from Rome through Etruria in a direct line to Narnia, now *Narni*, in Umbria, it there divided into two branches, the one stretching eastwards through Terni and Spoleto to Foligno, where it met the other, which passed through Careoli and Bevagna. It then continued its course to Nuceria, where it again branched off in two directions, the one passing through the district of Picenum to Ancona, and along the coast of the Adriatic to Fanum Fortunæ (Fano), where it met the other, which followed the more direct line of Intercisa or Furlo, and Forum Sempronii or Fossombrone. The Via Flaminia terminated at Ariminum. (Bergier, *Hist. des Grands Chemins.*)

FLAMINIUS, C., a general of the Roman republic. The most memorable event in his history is the terrible defeat which he sustained from Hannibal at the Thrasymene Lake, B.C. 217, in which he was slain, along with the greatest part of his army. See Roman History.

Flaminius, *T. Quintius* (B.C. 230–174), an illustrious general of the Roman republic. He distinguished himself chiefly in the wars between Rome and Greece, in the course of which he gained the celebrated victory of Cynoscephalæ over the Macedonians, B.C. 197. For the details of his various campaigns in Greece, see Roman History.

FLAMSTEED, John, one of the most laborious and distinguished of British practical astronomers, and the first who obtained the appointment to the Royal Observatory, was born at Denby, near Derby, Aug. 9, 1646. He received the elements of his education at the free school of that town, where his father carried on the business of a maltster. When fourteen years of age, imprudent bathing brought on a severe rheumatism, from the effects of which his limbs never entirely recovered. This induced him, when nineteen, to visit Ireland, for the purpose of consulting a notorious quack, who professed to cure all diseases by his *touch;* but, as might have been anticipated, he soon returned no better than he went.

Even at a very early age Flamsteed showed a decided inclination for mathematical and astronomical researches. The books which seem to have awakened his mind to such

studies were Sacrobosco's treatise *De Sphæra*, which he partially translated into English, and Street's *Astronomia Carolina;* but a present afterwards made to him of Kepler's *Tabulæ Rudolphinæ*, and Riccioli's *Almagestum Novum*, with a few other tracts on astronomy, confirmed his taste for that science; and he soon began to exhibit much ingenuity in the construction of astronomical instruments.

The state of his health, and perhaps also his father's circumstances, probably prevented his proceeding to the university with some of his schoolfellows. He remained at Derby for several years, eagerly engaged in practical astronomy; and there, about 1667, gave a practical demonstration of the true principles of the equation of time; and he appears decidedly to have been the first astronomer who brought into common use the method of simultaneously observing the right ascension of the sun and stars, a mode by which the true place of any star is determinable by means of meridional altitudes and transits.

His first astronomical communication to the Royal Society was made in 1669, under an assumed anagram, which was soon detected by Oldenburg, the secretary. In the same year, in his own name, he communicated to the president, Lord Brouncker, his calculation of the solar eclipse, that had been omitted in the Ephemerides, with some other astronomical observations. This paper was submitted to a committee of the Royal Society, and obtained for its author the applause of the astronomical world.

In the following year he was invited by his father to London, and introduced to the great philosophers of the capital. He had now opportunities of seeing the best astronomical instruments then known, far surpassing those he had been accustomed to make with his own hands; and he was well received by his warm friend and admirer Sir Jonas Moore, who furnished him with several delicate instruments, among which was Townley's micrometer. In returning to Derby he visited Cambridge, and entered himself of Jesus College, where he became acquainted with Barrow and Newton, with whom he long kept up a close correspondence.

In 1672 he sedulously applied to the study of dioptrics, with the view of improving his astronomical apparatus, and continued most assiduously his celestial observations, which from time to time afforded communications to the Royal Society.

In 1673 he composed his treatise on *The True and Apparent Places of the Planets when at their Greatest and Least Distance from our Earth;* a work of which Newton availed himself in the first edition of *The Principia.* In the same year Flamsteed obtained the degree of master of arts at Cambridge.

In 1674 Flamsteed published his Ephemeris, and drew up a table of the tides, which Sir Jonas Moore presented to Charles II. and his brother the Duke of York. Flamsteed had also constructed two barometers, then uncommon instruments; which, through the same friendly hand, were presented to the royal brothers and graciously received.

Flamsteed had decided on entering the church; and, although Moore had urged his settling in another vocation in London, he persevered in his determination, and was admitted into holy orders in 1675; but he never obtained any higher preferment than the small living of Burslow in Surrey, to which he was presented by Lord Keeper North in 1684, the year in which he lost his father.

Sir Jonas had determined on establishing Flamsteed in his own private observatory at Chelsea, when the enormous errors of the astronomical tables then in use were brought under the notice of King Charles II., who determined to found an observatory. Through the good offices of Moore, Flamsteed was appointed the first "astronomical observator;" and he immediately began his celestial observations at the queen's house at Greenwich until the observatory should be finished, which it was in 1676. It was named *Flamsteed House;* and from this era Mr Baily dates the commencement of modern astronomy.

The salary was only L.100 a-year, and that not always punctually paid. Here the indefatigable Flamsteed collected the enormous mass of materials from which he furnished the first trustworthy catalogue of the fixed stars; and it was on his observations chiefly that Newton laid the foundation of his *Lunar Theory.* Yet Flamsteed was ill supported by the government. His instruments, chiefly procured at his own expense, from his scanty salary and the emoluments of his living, were very imperfect; and his requests for assistance were unheeded. The government promised much, but did nothing; though a very small portion of what was squandered during this reign on mistresses and panderers to the low pleasures of the court would have completely furnished the best observatory in Europe, and enabled this acute and indefatigable man to have still farther extended the sphere of astronomical science and the honour of his country.

His *Doctrine of the Sphere* appeared in the mathematical treatise of his friend Moore, in 1681.

Much light has been thrown on the private history of Flamsteed, and the unjust treatment he alleged he had received at the hands of some of the brightest names in the galaxy of British science, by F. Baily's discovery in 1832 of a vast mass of Flamsteed's papers and correspondence, which was published in 1835 at the expense of the admiralty. The correspondence gives Flamsteed's own version of the disputes between him and some of the most eminent philosophers of the day; and it would be unjust from such *ex parte* statements to derogate from the fair fame of a Newton or a Halley on the accusations of a man acknowledged to have been of a very irritable temper, and indignant at what he conceived to be gross injustice to himself. The defence of Sir Isaac Newton from his accusations has been partly undertaken by Dr Whewell; and the public have at length received the most complete and satisfactory vindication of this illustrious philosopher in the *Memoirs of the Life, Writings, and Discoveries of Sir Isaac Newton*, by Sir David Brewster.

Flamsteed had very freely communicated his astronomical discoveries to Cassini, who had ever treated him with equal candour; and it is not denied that he had furnished Newton with every lunar observation he had made before the publication of the first edition of the *Principia*, which appeared in 1685. Flamsteed's unwillingness or refusal to contribute his observations to Sir Isaac, after their quarrel, arose from his considering himself unjustly treated by Newton and his colleagues of a committee appointed by government to examine and report on the papers of the royal astronomer. This committee consisted of Sir Isaac Newton, Sir Christopher Wren, Dr Gregory, Dr Arbuthnot, and Mr Roberts. They had, it seems, broken a seal, at the command of the sovereign, which Flamsteed had put on his imperfect catalogue of stars, on delivering it to the committee. Of this he bitterly complains. Though the report of the committee was in favour of printing Flamsteed's papers, what seems chiefly to have irritated him was, that the superintendence of printing them was not given to persons of his appointment, but confided by the committee to Dr Halley.

Flamsteed demanded back his papers, which was refused, as they were considered public property; and he commenced a law-suit for their recovery, the result of which Mr Baily could not learn; but the correspondence of Flamsteed states, that after he had spent L.200 in this suit, they were delivered up to him by Newton.

The zealous Flamsteed had expended on instruments and in completing his catalogue of stars, not only his salary, but L.2000 more, and he determined to print it. The husband of Queen Anne, on learning this, offered to print it at his own expense, and paid for the first edition; but Prince George dying in 1708, Flamsteed lost the aid of this liberal patron. During great part of the reign of Queen Anne, the astronomer royal was not on good terms with the

government, which he ascribed to the influence of Newton and Halley. On the death of the Queen in 1714, and of Newton's court patron, the Earl of Halifax, in the following year, Flamsteed asked and obtained from the treasury possession of the remaining 300 copies of Halley's publication of the first and second volumes of the *Historia Cœlestis;* a large portion of which he immediately committed to the flames, preserving only about 97 sheets of each volume, which was printed as he wished, and which he afterwards introduced into the first volume of this great work.

From 1715 to 1719 Flamsteed was earnestly employed in publishing this noble work, which he did not live to see completely printed. After his death the publication was continued by his widow, aided by Mr Crosthwaite, the observatory assistant, and Mr Abraham Sharp, a steady friend of the author. It was completed in three folio volumes in 1723. His valuable *Atlas Cœlestis* did not appear till 1753.

Of these works it is sufficient to say, that considering the period, and the then comparatively imperfect state of astronomical instruments, they are highly honourable to the author and his country, and mark an important era in the history of practical astronomy.

The first volume of the *Historia Cœlestis* contains his observations at Derby and Greenwich on the fixed stars, planets, Jupiter's satellites, comets, and spots on the sun's disk; the second contains the transits of stars and planets over the meridian, together with their places determined by such observations; the third volume contains an account of the methods and instruments used by Tycho Brahe and himself; catalogues of the fixed stars by Ptolemy, Ulugh Beigh, Tycho, the Landgrave of Hesse, and Hevelius, together with his own British catalogue of the true places of 2884 stars.

Flamsteed, though of a feeble constitution, and worn down by incessant labour, lived to his seventy-third year, when he was rather suddenly carried off by strangury on 31st December 1719. (T.S.T.)

FLANCH, or FLANGE, a projecting rim or rib on anything which serves to unite it with something else; as exemplified in the flat rims by which cast-iron pipes are frequently connected.

FLANDERS, formerly an extensive country of Europe, now forming the provinces of East and West Flanders in Belgium, part of the province of Zeeland in Holland, and the department du Nord in France. See HOLLAND, BELGIUM, FRANCE, &c.

FLANNAN ISLANDS, a group of small islands, seven in number, 12 miles N.W. of the Island of Lewis. They are wild, rocky, and uninhabited; but afford excellent pasture for sheep. From existing remains of sacred edifices, they appear to have been formerly the residence of the Culdees or some other religious order.

FLANNEL, a woollen stuff, composed of a woof and warp, and woven after the manner of baize.

Dr Black assigns as a reason why flannel and other substances of the same kind keep the body warm, that they compose a rare and spongy mass, the fibres of which touch each other so lightly that the heat moves slowly through the interstices, which being filled only with air, and that too in a stagnant state, give little assistance in conducting the heat. From the experiments of Count Rumford, it appears that there is no relation between the power which the substances usually worn as clothing have of absorbing moisture, and that of keeping the body warm. Having provided a quantity of several of these substances (as mentioned below), he exposed them, spread out upon clean china plates for the space of twenty-four hours to the warm and dry air of a room which had been heated by a German stove for several months, and during the preceding six hours he had raised the thermometer to 85° of Fahrenheit; after which he weighed equal quantities of the different substances with a very accurate balance. They were then spread out upon a china plate, and removed into a very large uninhabited room upon the second floor, where they were exposed forty-eight hours upon a table placed in the middle of the room, the air of which was at 45° of Fahrenheit. At the end of this time they were weighed, and then removed into a damp cellar, where they were placed on a table in the middle of the vault, the air of which was at the temperature of 45°, and, by the hygrometer, seemed to be fully saturated with moisture. In this situation they were suffered to remain three days and three nights, the vault being all the while hung round with wet linen cloths, to render the air as completely damp as possible. At the end of three days they were weighed, and the weights at the different times were found as in the following table:—

	Weight after being dried in the hot room.	Weight after coming out of the cold room.	Weight after remaining 72 hours in the vault.
Sheep's wool	Parts 1000	1084	1163
Beaver's fur		1072	1125
The fur of a Russian hare		1065	1115
Eider down		1067	1112
Silk ... Raw single thread		1057	1107
Silk ... Ravellings of white taffety		1054	1103
Linen.. Fine Lint		1046	1102
Linen.. Ravellings of fine linen		1044	1082
Cotton wool		1043	1089
Ravellings of silver lace		1000	1000

In regard to these experiments Count Rumford observes —that though linen, from the apparent ease with which it receives dampness from the atmosphere, seems to have a much greater attraction for water than any other, yet it would appear, from what is related above, that those bodies which receive water in its unelastic form with the greatest ease, or are most easily wet, are not those which in all cases attract the humidity of the atmosphere with the greatest avidity. "Perhaps," says he, "the apparent dampness of linen to the touch arises more from the ease with which that substance parts with the water it contains than from the quantity of water it actually holds; in the same manner as a body appears hot to the touch in consequence of its parting freely with its heat; while another body which is really at the same temperature, but which withholds its heat with great obstinacy, affects the sense of feeling much less strongly. It is well known that woollen cloths, such as flannels, &c., worn next the skin, greatly promote insensible perspiration. May not this arise principally from the strong attraction which subsists between wool and the watery vapour which is continually issuing from the human body? That it does not depend entirely on the warmth of that covering, is clear; for the same degree of warmth produced by wearing more clothing of a different kind does not produce the same effect. The perspiration of the human body being absorbed by a covering of flannel, it is immediately distributed through the whole thickness of that substance, and by that means exposed, by a very large surface, to be carried off by the atmosphere; and the loss of this watery vapour which the flannel sustains on the one side by evaporation, being immediately restored from the other, in consequence of the strong attraction between the flannel and this vapour, the pores of the skin are disencumbered, and they are continually surrounded by a dry and salubrious atmosphere."—(*Philosophical Transactions,* No. 483.)

FLAT, in *Music.* See MUSIC.

FLAVEL, JOHN, an English nonconformist divine of great learning and ability, was born at Broomsgrove in Worcestershire in 1627. He was the eldest son of Mr Richard Flavel, described in contemporary records as "a

painful and eminent minister." By this parent he was educated with the utmost care, first at home and afterwards at the grammar-schools of Broomsgrove and Haslar. Finally, he was entered of University College, Oxford, where he greatly distinguished himself in all the academical pursuits of the place. Soon after taking orders in 1650, he obtained a curacy at Deptford, and ingratiated himself so completely with the people by the earnest fervour of his eloquence in the pulpit, and the faithful discharge of his other ministerial duties, that on the death of the vicar he was unanimously appointed to succeed him. From Deptford he removed to Dartmouth, to which he had been tempted as affording a wider sphere of usefulness, though in a pecuniary point of view he suffered considerably by the change. In 1662 the Act of Uniformity was passed, and Flavel, refusing to comply with its requirements, was ejected from his living. He still continued, however, to preach and administer the sacraments privately till the Oxford Act of 1665 compelled him to retire to Slapton, five miles from the scene of his official labours, and for the next twenty years he underwent every kind of hardship and persecution in common with his nonconforming brethren till a presentiment of danger compelled James II. to abate somewhat the severity of his brother's enactments against them. After the expulsion of the Stuart dynasty, Flavel was urgently pressed to accept various calls that were offered him by metropolitan congregations; but he refused to accept any of them, and continued to labour among his parishioners of Dartmouth till his death in 1691, shortly after the union of the Independent and Presbyterian churches, an event which gave him very great joy on his death-bed. Flavel was four times married, but does not appear to have left any family behind him. His principal works are his *Treatise on the Soul of Man; The Fountain of Life, in forty-two Sermons; The Method of Grace; A Token for Mourners; Husbandry Spiritualized; Navigation Spiritualized.* It cannot be denied that these works are in their totality heavy and cumbrous in their structure; but they have received a very scant measure of justice at the hands of most English writers who have thought it worth while to notice them. They contain many isolated passages of striking merit, even in a literary point of view, and many detached thoughts of rare and daring originality. If it be true, as Johnson says, that it is the lot of Milton to be more admired than read, it is equally true that Flavel, less fortunate than his contemporary, has the misfortune to be slightingly dismissed by many persons who prove by the very character of their criticism that they have never read a line of his works. This misfortune, however, he shares with the majority of those divines who are generally classed together as the "Puritan."

FLAX, the fibre of *Linum usitatissimum*, a plant of the natural order *Linaceæ*, which is spun into thread and woven into linen textures. (See Botany, vol. v., p. 187.) The seeds yield on expression a large quantity of oil, known as linseed-oil; and the residue, called linseed-cake, is much employed to fatten cattle. Flax has been cultivated from the earliest ages in Great Britain and many other countries; but in general we have been in the habit of importing a large proportion of our supplies, particularly from Russia. The fibre of *Phormium tenax*, or New Zealand flax as it is commonly called, is said to exceed every other kind of fibre in strength, and has been imported in some quantity as a substitute for hemp in the manufacture of canvas and cordage. For the culture of flax, see Agriculture, vol. ii., p. 332, &c. (See also Spinning; Linen; Hemp.)

The quantity of flax imported into Great Britain has for a considerable number of years been gradually increasing. Twenty years ago the annual importation was about 48,000 tons; ten years since it had increased to about 65,000 tons; and at the present time it is about 80,000 tons. The proportion per cent. of this quantity imported from different countries may be judged of by the following table, calculated on the average imports of the years 1840, 1844, and 1849:—

	1840.	1844.	1849.
Russia	69·0	7·0	74·0
Prussia	11·0	10·0	10·0
Holland	9·0	8·0	6·5
Belgium	6·5	7·0	4·0
France	3 5	3·5	1·5
Other countries	1·0	1·5	4·5

During the last few years great efforts have been made to extend and improve the manufacture of this valuable fibre in various parts of the world. The increase under the last head in the preceding table, for 1849, is chiefly due to the importation of flax from Egypt. It must be remembered that, in addition to the above-mentioned quantity of flax annually imported, the manufacturers of England have consumed rather more than a quarter as much again, cultivated in various parts of the British empire, but chiefly in Ireland. This proportion has also considerably increased during the last twenty years, and a most marked improvement in the quality of the flax itself has also been effected; a change in great measure to be traced to the efforts of the Royal Society for the Promotion and Improvement of Flax in Ireland. At the thirteenth annual meeting of that society the number of acres under flax cultivation in Ireland was given as follows:—

Years.	Acres.	
1848	53,863	value L.15 per acre.
1849	60,314	...
1850	91,040	...
1851	138,619	...
1852	136,009	..
1853	175,495	...

The value of flax depends in part on the climate and soil in which it is cultivated; and in part also on the mode in which the fibre is prepared, and on the care and skill with which the process is conducted. According to its quality, its value varies from about L.40 to L.180 per ton. Another circumstance which has given a considerable impetus to the cultivation of flax is the introduction of the late R. B. Schenck's new process of steeping. Formerly the separation of the fibre from the woody matter of the stem was effected by the process of "retting," of which there were three modifications—dew-retting, pond-retting, and river-retting. The stem of the plant consists essentially of two parts;—a wooden centre or core, the shove or boon, and the external fibrous portion, which, when separated from the former, constitutes the flax. These two are cemented together by a glutinous matter, not soluble in water alone, and which must be got rid of by some means before the pure fibre can be separated from the woody shove. The old mode consisted merely in exposing the flax stems to air and moisture, under circumstances favourable to fermentation or incipient putrefaction, so that the glutinous matter being destroyed, the fibre could then be easily separated from the shove. Whether this species of fermentation is effected by exposing the flax for some weeks to the action of the dew and rain spread over meadows, whether it is effected by steeping it in ponds or pits of stagnant water, or, lastly, by sinking it in large wooden frames in the current of a deep and slow flowing river, there are serious practical difficulties which have long directed the attention of ingenious men to the possibility of discovering a less objectionable mode of preparing flax. During the slow retting of the flax, certain putrid vapours are given off in large quantity, the water and the very air itself are poisoned; and this alone is no trifling objection to the process. So serious an objection, indeed, have these putrid exhalations been found to the use of water-retting, that in some districts of Belgium, in Hainault and Namur especially, it is forbidden by law, as being dangerous to "public safety and the health of the inhabitants." In Flanders, however, no such laws are in force, and it is there commonly believed that dew-retted flax is, of necessity, meagre and dry. Many different mo-

difications and peculiar modes of retting are followed in the various flax districts of Belgium, Holland, and France; and in different localities dissimilar modes of retting have long been in use, often involving very considerable variations in principle. Thus, at Courtrai the flax crop is dried in the field, and stored for some months in barns, before it undergoes the process of retting in the river Lys. In the district of Waes it is retted immediately after being gathered, the green stems being at once thrown into pits of stagnant water. As, however, the whole operation, in every kind of water-retting, depends on the amount of fermentation produced (which must be enough to insure the decomposition of the glutinous matter, but not enough to cause any injury to the fibre), the process is necessarily slow, tedious, and very uncertain, especially towards the close of the operation, because then the flax must be most carefully watched, in order to put a stop to the fermentation as soon as the desired effect is produced. A slight change of temperature, or exposure for a few hours when the fermentation is complete, may involve the ruin of the fibre. Dew-retting is of course even slower than water-retting; depending, as it necessarily does, on the nature of the season, and being greatly retarded by long-continued dry weather.

During the last half century various attempts have been made to effect the separation of the fibrous from the woody portion of the flax stem by chemical and mechanical means. In several cases the results at first appeared to be very promising, but in every instance it was soon found that there were insuperable practical objections. Among chemical agents, solutions of sulphuric acid, caustic potash, caustic soda, quicklime, and soft soap, were all in turn tried and discarded; and among mechanical processes, the ingenious contrivances of Mr James Lee and Messrs Hill and Bundy shared the same fate. Whatever may have been the comparative merits of the two processes of these rival inventors, in the course of a few years both were relinquished and forgotten. Various other ingenious mechanical arrangements have been devised, but hitherto they have had very little success.

Schenck's process, for which he obtained a patent in 1846, is undoubtedly a very important improvement. It consists merely in steeping the flax stems in warm water, heated artificially to the temperature best suited to fermentation. In this simple way the operation is rendered rapid and certain, all uncertainty from fluctuations in the temperature and weather is avoided, and the whole process is entirely under the command of the manufacturer. The temperature best suited for this purpose is about 80°, or from 80° to nearly 90°. Above this point the process proceeds too rapidly, and the fibre is almost sure to be more or less injured. The time required is from about 70 to 90 hours. It appears to be generally admitted that the warm-water steeping increases the percentage of fibre obtained from the flax stem over that obtained by the old modes of retting by nearly one-fifth; and that, whilst the fineness and spinning qualities of the fibre are increased, the strength is in no way weakened or diminished, unless the process be permitted to proceed too far,—an accident that need never happen, from the complete control over it which the manufacturer has throughout. Although there is no doubt as to the practical value of the use of warm water in flax-retting, yet the introduction of Schenck's process is far from removing all the difficulties of the flax manufacture; much still remains to be effected, and it is by no means improbable that ere long a yet more perfect process may be devised.

It is interesting to observe, that the use of warm water in the preparation of vegetable fibre is not altogether new, it having been employed by the Malays, and by the natives of Rungpoor, in Bengal. The process adopted at Bencoolen is stated by Dr Campbell to consist in steeping the stems of the hemp in warm water, in which it is allowed to remain for two days and nights. The old German process, called "Molkenröst," sometimes used in preparing the finer sorts of flax, is also, to some extent, an application of the same principle. In this mode of retting the flax was steeped for four or five days in a warm mixture of milk and water, and thus the desired degree of fermentation in the flax stems was produced. This operation must be distinguished from the more modern one in which sour milk was used, in order to give a good colour to linen,—a process introduced by the Dutch towards the middle of last century. The linen was boiled in a weak alkaline lye, and subsequently treated with sour butter-milk, for the purpose of aiding in removing the alkali, and dissolving the earthy impurities present in the fibre. Occasionally, also, salt of sorrel was used for the same purpose; and in 1775 Reuss states that sulphuric and muriatic acids might be used for the same end; but that being too costly, they had not as yet come into general use. Of course, all processes in which boiling or even hot water is used, are quite different in their mode of action from those in which only warm water is employed. When boiling-water is used, it is with a view of dissolving and removing the useless matters which incrust the fibrous parts of the plant; whilst, on the other hand, warm water is used to soften them, and to aid in their putrefaction or decomposition through the agency of fermentation. In 1787 much interest was excited in Ireland by the publication of a plan for improving the retting of flax by the action of hot water. In this scheme it was proposed to scald the flax-stems in boiling-water to soften them, and to remove a portion of the extraneous vegetable matters which they contain; and it was conceived that after this treatment the subsequent retting of the flax would be more rapid, certain, and manageable; so that time would be saved, the noisome process of pond-retting be obviated, and the result be to yield a stronger and whiter fibre. The minute and careful experiments of Hermbstaedt on the chemical principles involved in the retting of flax (made about the beginning of the present century) threw much light on the whole subject, and to some extent indicated the influence of temperature on the success of the operation.

Flax-cotton is a material prepared from flax, hemp, and other vegetable fibres, and which very nearly resembles the fibre of the *Gossypium* or cotton-plant. M. Claussen's ingenious process for making flax-cotton (patented August 1850) consists essentially in boiling the cut and crushed stems of the flax, hemp, or other plant, in a dilute solution of caustic soda, containing about $\frac{1}{2000}$th part of alkali. The fibrous matter is then removed, and plunged into a bath of dilute sulphuric acid, containing $\frac{1}{500}$th part of acid, in which it is boiled for about an hour. It is next transferred into a solution containing about ten per cent. of carbonate of soda; and, lastly, when it has remained in the latter for an hour, it is plunged into a weak solution of sulphuric acid, consisting of one part of acid to 200 or 500 parts of water; in this it is left for about half an hour, and the process is completed. The effect of these several processes is "to divide and split up" the fibre in a most remarkable manner, so as completely to alter its character. Flax thus treated is converted into a substance very nearly resembling cotton. It is probable that flax-cotton can be advantageously used in the manufacture of mixed fabrics, as it appears capable of being spun with wool, silk, and other fibres; it may, therefore, perhaps hereafter lead to several new and important practical applications.

The idea of modifying the fibre of flax and hemp, so as to convert it into a kind of cotton, is by no means new. In 1747 Lilljikreuzes and Palmquist described a mode of converting flax into "cotton," by boiling it for some time in a solution of caustic potash, and subsequently washing it with soap. In 1775 considerable quantities of refuse flax and hemp were converted into "flax-cotton" by Lady

Flaxman.

Moira, with the aid of T. B. Bailey, of Hope, near Manchester. The full details of the process employed do not appear to have been published; but from Lady Moira's letters in the *Transactions of the Society of Arts* for 1775, it appears that the fibre was boiled in an alkaline lye, or a solution of kelp, containing carbonate of soda, and subsequently scoured. The result of this was that "the fibres seem to be set at liberty from each other," after which it may be "carded on cotton cards." It appears that at this time flax-cotton "was made and sold at 3d. a pound;" and Lady Moira states, that she believes that it takes colours better than flax. It is curious to observe the fate of Lady Moira's scheme: she says,—"I have no reason to be vain of the samples I have sent you; they merely show that the material of flax-cotton, in able hands, will bear manufacturing, though it is my ill fortune to have it discredited by the artizans who work for me. I had, in Dublin, with great difficulty, a gown wove, and three waistcoats; but had not the person who employed a weaver for me particularly wished to oblige me, I could not have got it accomplished."

Subsequently to this, several attempts were made in Germany to convert flax into a fibre resembling cotton. In 1777, Baron Meidinger proposed to convert flax into a sort of cotton, by the action of alkaline solutions, &c. In 1780 a factory was established at Berchtoldsdorf, near Vienna, for the practical working of this process; and similar plans were subsequently brought forward by Kreutzer in 1801, Stadler and Haupfner in 1811, by Sokou in 1816, and by several others. At the factory at Berchtoldsdorf, not only was flax converted into cotton, but likewise a useful cotton-like fibre was prepared from tow and refuse flax; and the same is said to have been done by Haag, near Pressburg, in 1788, by Göbell in 1803, and Segalla in 1811. Whether these various plans failed from the effects of jealousy and opposition, like that which prevented Lady Moira from introducing her "flax-cotton," is unknown, but it does not appear that any of them were long persevered in: it is probable, that in most cases the neighbouring manufacturers set themselves against the introduction of flax-cotton: for Beckmann, who speaks of its manufacture near Brunswick, states that the work-people determined not to use the new material, though at the same time he observes, that excellent fustians were made which could not be distinguished from those manufactured with ordinary cotton. The extreme similarity of flax-cotton to ordinary cotton is also remarked by Des Charmes (1799), who states, that if the staple be cut before it is carded, it is not possible to distinguish it from cotton, either in its raw state, or when manufactured. The matter was subsequently investigated by Berthollet, by Gay Lussac, and by Giobert, who employed alternately steepings in hot solutions of soap, alkali, and sulphuric or muriatic acid. Berthollet observes, that equally fine cotton is obtained from the commonest refuse tow as from the best flax.

For some valuable information on fibrous materials, the produce of India, which may be cheaply and usefully substituted for Russian hemp and flax, see "The Fibrous Plants of India fitted for Cordage, Clothing, and Paper," by J. Forbes Royle, M.D., F.R.S., Lond. 1855; and also an article, entitled "Indian Substitutes for Russian Produce" in the *Edinburgh Review* for July 1855.

FLAXMAN, John, an eminent English sculptor, born at York July 6, 1755, was the second son of John Flaxman, a moulder in plaster, who kept a shop in London for the sale of his figures. He was of a weakly constitution, and slightly deformed, which prevented him from mingling in the robust pastimes of youth; but he was not idle. Behind his father's counter, with drawing materials before him, he busily employed himself in transferring to paper representations of the numerous figures with which he was surrounded. But he did not confine himself to copying alone. Young as he was, he had dipped into the Iliad, and actually attempted to design historical illustrations of that immortal epic. His education seems to have devolved principally upon his parents; and as his thirst for knowledge was great, the superintendence of his studies must have been an easy task. At his books and models he laboured incessantly, and before he entered his tenth year he had made a great number of small models in plaster of Paris, wax, and clay, some of which are still preserved; and, besides being interesting as the first efforts of genius, they possess considerable merit as works of art. At ten years of age a salutary change took place in his health; he became strong, lively, and active; and the crutches by means of which he had hitherto walked were thrown aside. With renovated health he came to the determination to follow sculpture as a profession. In his father's shop, where he assiduously pursued his studies, he learned form and proportion from the casts of antique statues which it contained; whilst in the woods and fields he was supplied with new images and ideas of beauty. At the house of a Mrs Mathew, whose husband had been attracted to the youthful sculptor, Flaxman often spent his evenings hearing her read Homer and Virgil, and discourse upon sculpture and poetry. By this lady he was encouraged to study the dead languages; and although he never attained to great scholarship, he obtained such a knowledge of Greek as enabled him to embody the ideas of the ancient poets in a manner which no modern artist has surpassed. He embodied those passages which caught his fancy whilst he sat listening to Mrs Mathew; and the taste displayed in these juvenile efforts induced a gentleman to order six large drawings in chalk, the subjects being chosen from antiquity. The praise bestowed upon these gave new impulse to his genius, and strengthened that consciousness of superior power which he early experienced; yet he never overrated himself, nor allowed his industry to relax on account of the flatteries of friends, but continued to labour assiduously, well knowing that it was only in this manner that great eminence was to be attained in art.

In his fifteenth year Flaxman became a student of the Royal Academy, and soon made himself known by assiduous and enthusiastic application. In the same year he carried off the silver medal; and in due time became a candidate for the gold one, but was unsuccessful. This defeat, however, only increased his assiduity; but finding himself now compelled to labour for bread, he employed himself with the Wedgewoods, the enterprizing potters, to make designs for adorning their wares. His sketches consisted chiefly of small groups in very low relief, the subjects being taken from ancient poetry and history. Previously to this period the porcelain of England had little external beauty to recommend it; and the genius of Flaxman may be said to have created this branch of art in his native country. In 1782 he quitted the paternal roof, and married Miss Ann Denman, a lady of many virtues and accomplishments, in whose society he enjoyed much domestic happiness. During the ten years which preceded this event he had exhibited some thirteen works at the Royal Academy, but, from the pecuniary difficulties under which he laboured, none of these were executed in marble. Shortly after his marriage he formed the resolution of studying at Rome; and at the end of five years of incessant labour, during which he executed several monuments and other works of considerable merit, he was enabled to carry his design into execution. In Rome he executed a number of works. For three individuals of his own country he illustrated Homer, Æschylus, and Dante. These designs are splendid, being varied with great skill, and drawn with a fine sense of the beautiful and harmonious in composition. Of works in marble he executed a small-size group of Cephalus and Aurora; a statue of Lord Mansfield; a group representing

the fury of Athamas, from Ovid's *Metamorphoses*, consisting of four figures of the heroic size; and the restoration of that splendid torso which is generally believed to be a fragment of a Hercules. This last undertaking was as difficult as it turned out to be thankless. He not only completed the figure of Hercules, but added another of Omphale. But this statue did not give satisfaction to the connoisseurs of Italy, and Flaxman caused it to be destroyed some time previously to his death, without any injury to his fame. The remains of ancient sculpture in Rome, and in other cities of Italy, engaged not a little of his attention. He executed numerous drawings, and made a great many memoranda, the most valuable of which were subsequently embodied in his lectures on sculpture. He had been elected a member of the academies of Florence and Carrara; and after seven years' residence abroad, he at length returned home.

Flaxman's statue of Lord Mansfield had raised the expectations of his countrymen to a high pitch. In 1797 he was elected associate of the Royal Academy, during which year he sent to the exhibition three sketches in bas-relief from the New Testament, and a monument to Sir William Jones. The sketches are distinguished for their elegance of grouping. The monument is a bas-relief, but not one of the artist's most fortunate efforts in that line. In the forty-fifth year of his age Flaxman was elected a member of the Royal Academy, and, as is usual on such occasions, presented to the institution a work of art. His offering on this occasion was a marble group of Apollo and Marpessa; the conception of which is fine, though the workmanship is not so good. In the mechanical use of the chisel he never excelled. It was now his ambition to be employed upon some great national work, and he proposed to make a statue of Britannia two hundred feet in height, but the project was not carried into execution. His fame, however, was now firmly established, and commissions flowed rapidly in. A quick succession of noble works followed from his hand, one of which, a monument in memory of the family of Sir Francis Baring, is considered among the greatest efforts of his genius. One of his biographers remarks with respect to it, "This is one of the finest pieces of motionless poetry in the land." Of historical monuments Flaxman executed several, but they are not equal to his other works. They have been admired for the fine sentiment which pervades them, but their execution is considered by many as coarse and heavy. The statue of Sir Joshua Reynolds is one of his best productions. But the works he loved most were those which embodied poetical passages in the Bible; and of these he executed a great number. In 1810 the Royal Academy created a professorship of sculpture, and bestowed it upon Flaxman. His lectures are ten in number. The style is rather heavy; yet although his compositions are destitute of those flashes of poetry which irradiate the pages of Fuseli, they display a very comprehensive knowledge of the subject, much sound sense, and are more calculated to convey definite information to the student than those of the other artist above named. But if the offspring of his pen was cold and uninformed with ideal beauty, the productions of his pencil and chisel display an exuberance of imagination. His sketches and drawings are very numerous. Amongst the works which he illustrated were the Pilgrim's Progress, Sotheby's translation of Oberon, and Hesiod. These designs are in all respects fully equal to his other works, and unsurpassed by anything which ever was executed in that line. During the last ten years of his life Flaxman produced some of his noblest works. Amongst these were the group of the Archangel Michael vanquishing Satan, the Shield of Achilles, Psyche, the Pastoral Apollo, and the statues of Michael Angelo and Raffaelle. The first is a work of the highest merit, and worthy of the great poem which it illustrates. "In the Psyche and the Pastoral Apollo," says Mr Allan Cunningham, "the genius of him who illustrated Homer is sufficiently apparent; a certain austere composure is breathed over them. The Michael Angelo and the Raphael are poetic, yet real; heroic, yet familiar; and their costume, though not antique, is at once historic and picturesque." Flaxman's statues of Burns and Kemble, executed about the same time, are scarcely so happy. Amongst his other works were monuments to Collins at Chichester, and to Earl Howe in St Paul's; and statues of Washington, Nelson, Pitt, and Sir John Moore. They are of various excellence, yet all more or less bear the impress of genius and taste. But the career of this great sculptor was drawing to a close. In the beginning of December 1826 he was seized with an inflammation of the lungs, which terminated fatally on the 7th of the same month.

In stature Flaxman was small, and his figure was slim. In manners he was mild, gentle, and placable; and his mind, whilst it was rich in the gifts of genius, was embued with unaffected piety. Of his works there are four kinds; the religious, the poetic, the classic, and the historical. In each of these he has left specimens which entitle him to rank very high as an artist, but in all he has not attained the same degree of excellence. In the historical and the classic he was less successful; but in the religious and poetic he has been surpassed by no modern sculptor in purity, simplicity, and taste. His religious compositions consist of groups and figures embodying moral and spiritual passages from Scripture. They are generally of small dimensions, but very numerous. His mind was essentially poetical; and his productions are embued with the finest inspiration. It was probably of some of these works that Sir Thomas Lawrence spoke when he said of Flaxman, "His solitude was made enjoyment to him by a fancy teeming with images of tenderness, purity, or grandeur. His genius, in the strictest sense of the words, was original and inventive." His lectures were published in 1829, in one vol. 8vo, illustrated with fifty-two plates. (J. F. S.)

FLEAM, in *Farriery*, the name given to several kinds of instruments used to open veins for letting blood.

FLECHE, La, a town of France, department of Sarthe, and capital of a cognominal arrondissement, stands in a pleasant valley on the right bank of the Loir, 24 miles S.S.W. of Mans. The streets are wide and clean, and ornamented with fountains. It is chiefly noted for its royal military college, formerly a celebrated Jesuit's college, founded by Henri IV. in 1603, and which numbered among its students Descartes, Mersenne, and Prince Eugene. Among other public buildings are the Church of St Thomas, with a spire (*flèche*), from which the town takes its name, the town-hall, court-house, and hospital. The vicinity is fertile and well cultivated. Pop. (1851) 6543.

FLÉCHIER, Esprit, bishop of Nismes, one of the most celebrated preachers of his age, and author of a number of works, was born at Pernes, a small town in the diocese of Carpentras, on the 10th of June 1632, and educated under the eye of his uncle, Father Audifret, general of the Congregation of Christian Doctrine, a learned and estimable man. According to the constitution of the congregation, Fléchier, having completed his own education, was immediately employed in teaching. In 1659, when only twenty-seven, he professed rhetoric at Narbonne, and there pronounced the funeral oration of M. de Rebé, archbishop of that city. A few months afterwards, on the death of Audifret, Fléchier laid aside the habit of the *Doctrinaire*, and proceeded to Paris, where he was at first employed in the humble occupation of a parochial catechist; but he soon made himself known by his Latin and French poetry, and particularly by a description in Latin verse of the brilliant carousal, *Circus Regius*, given by Louis XIV. in 1602. This was the commencement of Fléchier's reputation. He

Fléchier. was now entrusted with the education of Louis Urbain Lefevre de Caumartin, afterwards intendant of finances and counsellor of state; and as the house of his pupil's father was then frequented by the most considerable personages both of the court and the city, Fléchier was introduced into the first society, and soon made many friends for himself by his virtues and talents. The Duke of Montausier declared himself his patron, and procured him the place of reader to the Dauphin. The sermons of Fléchier increased his reputation, which was afterwards raised to the highest pitch by his funeral orations. Having been chosen to pronounce that of Madame de Montausier, he displayed so great talent on the occasion, that his discourse opened to him the doors of the French Academy, into which he was received in 1673, in the room of M. Godeau, bishop of Venice. The favours of the court now flowed upon Fléchier. The king gave him successively the abbey of St Leverin, in the diocese of Poitiers, the office of almoner to the dauphiness, and, in 1685, the bishopric of Lavaur, accompanying his kindness with the most flattering expressions of favour and regard. "I have made you wait a little for a place which you have long merited," said the monarch; "but I did not wish to deprive myself sooner of the pleasure of hearing you." From the see of Lavaur Fléchier was, in 1687, translated to that of Nismes, which was more valuable, and also accounted more honourable. His own wish was to remain at Lavaur; but the king overcame his repugnance to the proposed translation by making him sensible that he would be more useful to the church at Nismes than at Lavaur, and that in the former place there was more labour to be performed and more good to be done. In fact the Calvinists were very numerous at Nismes; and although several had made abjuration, their conversion was at best but equivocal. But Fléchier, by his prudent conduct, in which zeal was tempered by charity, brought back the greater number of these sectaries to the bosom of the church, and made himself esteemed and beloved even by those who declined to abjure their faith. During the troubles in the Cévennes he softened, as much as in him lay, the rigour of the edicts, and showed himself so sensible of the evils of persecution, and so indulgent even to what he regarded as error, that his memory was long held in veneration amongst the Protestants of that district. In the famine which succeeded the winter of 1709, he did much to alleviate the prevalent distress, by assisting the poor in his diocese without regard to their religious tenets; alleging that all alike were his children. He also published an eloquent pastoral letter on the subject of a cross of St Gervais, which, it was pretended, worked miracles, and warned his flock against those lying wonders by which the credulity of the people has frequently been abused. This appears to have been amongst his last efforts in the cause of truth and religion. He died at Montpellier on the 16th February 1710, at the advanced age of seventy-eight. "He died," says D'Alembert, "lamented by the Catholics, regretted by the Protestants, and having always exhibited to his brethren an admirable model of zeal and charity, simplicity, and eloquence."

Fléchier's works are, 1. *Antonii Mariæ Gratiani de Vita Joannis Francisci Commendoni Cardinalis*, libri iv., Paris, 1699, in 12mo; 2. *La Vie du Cardinal Commendon*, Paris, 1671, in 4to; 3. *De Casibus Virorum Illustrium autore Antonio Maria Gratiano, opera et studio Sp. Flecherii*, Paris, 1680, in 4to; 4. *Histoire de Théodose-le-Grand*, Paris, 1679, in 4to, composed for the education of the dauphin; 5. *Histoire du Cardinal Ximenes*, Paris, 1693, in 4to; 6. *Oraisons Funèbres*, 1681, in 4to and in 12mo; 7. *Panégyriques des Saints*, Paris, 1690, in 4to; 8. *Sermons de Morale prêchés devant le Roi, avec des Discours synodaux et les Sermons prêchés par Fléchier aux Etats de Languedoc et dans sa Cathédrale*, in 3 vols. 12mo; 9. *Œuvres Posthumes contenant ses Harangues, Compliments, Discours, Poésies Latines, Poésies Françaises*, Paris, 1712, in 12mo; 10. *Mandements et Lettres pastorales, avec son Oraison Funèbre par l'Abbe du Jarry*, Paris, 1712, in 12mo; 11. *Lettres Choisies sur divers sujets*, Paris, 1715, in 2 vols. 12mo; 12. *Relation d'un Voyage en Auvergne*. The only collection yet published of the works of Fléchier is that of the Abbé Ducreux, canon of Auxerre, which appeared under the title of *Œuvres Complètes de Messire Esprit Fléchier*, Nismes, 1782, in 10 vols. 8vo. If we except the History of Theodosius, pulpit eloquence is the only branch of the belles-lettres cultivated by Fléchier in which he excelled. His Funeral Orations have been compared with those of Bossuet, without attending to this distinction, that comparisons become useless between two kinds of genius which are totally different. That of Bossuet was sublime throughout. Fléchier, on the other hand, was only remarkable for the nobleness of his thoughts and the harmony of his diction. It is true that he possessed in an eminent degree these two qualities of an orator, and that nobody has carried the latter further than he; but even in that department where he has been most successful Fléchier is not without faults, and may be reproached with an ambition of giving point to his thoughts, an affectation of symmetry in the style, and a love of antitheses, all at variance with the principles of good taste. But if his funeral orations and sermons lose much of their merit by a too measured elegance, his pastoral instructions and synodal discourses are wholly free from such affectation, indeed as remarkable for simplicity of style as for generosity of sentiment, and that indulgent spirit which laments whilst it combats error, and which, repudiating all attempts at persecution, seeks to win men over to the right way, not by the instrumentality of fear, but through the medium of their understanding and affections. "C'est dans ces ouvrages," says a distinguished French critic, "que la philosophie elle-même apprendra l'usage qu'on doit faire des luminères et du sentiment, et se convaincra que l'humanité n'a pas de consolation plus solide que la religion, comme la politique n'a pas de meilleur appui." (J. B—E.)

Flecknoe || Fleet.

FLECKNOE, Richard, a poet and dramatic writer in the reign of Charles II. He was an Irishman by birth, and was originally a priest of the Order of Jesus. Like many of the small wits and minor poets of that day, Flecknoe owes the rescue of his name from oblivion to the satirical genius of Dryden. That satirist availed himself of Flecknoe's name as a stalking horse from behind which to assail the poetaster Shadwell, who had been appointed to replace him in the laureateship. The opening lines of this satire may be quoted as a specimen of the whole:—

All human things are subject to decay;
And when fate summons, monarchs must obey.
This Flecknoe found, who, like Augustus, young
Was called to empire, and had governed long;
In prose and verse was owned without dispute
Throughout the realms of nonsense absolute, &c. &c.

It is but fair, however, to remark, that clever and effective as this poem is, it is in its application to Flecknoe utterly unjust. Flecknoe was the author of several plays, one of which was acted with considerable success, and also of many minor pieces, which, though possessing no great merit in the matter of versification, nevertheless contain many happy turns of thought and felicities of expression. His most important works were the following:—

Les Demoiselles à la Mode, printed in 1677, and addressed to the Duke and Duchess of Newcastle; *Ermina, or the Chaste Lady*; *Love's Dominion*, printed in 1654; and *The Marriage of Oceanus and Britannia*. His other works consist of, 1. *Epigrams and Enigmatical Characters*, 1670, in 8vo; 2. *Miscellanea*, or Poems of *all* sorts, with divers *other* pieces, 1653, in 12mo; 3. *Diarium*, or the Journal, divided into twelve Jornadas, in burlesque verse, London, 1656, in 12mo. Flecknoe died in 1678.

FLEECE, the covering of wool shorn from a sheep. See Wool.

FLEECE, Order of the Golden, one of the most eminent orders of knighthood in Europe, was founded in 1430 by Philip III. duke of Burgundy. By its foundation his successors were declared hereditary grand-masters; and thus the title passed to the imperial house of Austria with the Burgundian inheritance, and thence to the Spanish line of the same house after the death of the emperor Charles V. When the Spanish Netherlands, however, became Austrian, and the Bourbons became monarchs of Spain, the grandmastership was claimed by the archdukes of Austria. Hence at present the Spanish and the Austrian sovereigns alike confer the order, and at both courts it gives the highest rank.

FLEET, a navy or a squadron of ships of war; or a num-

ber of ships in company, whether ships of war or of commerce.

FLEET PRISON. See LONDON.

FLEETWOOD, a rising seaport and watering-place in Lancashire, at the mouth of the Wyre, and connected with Preston by a railway 22 miles in length. Fleetwood dates its rise from 1836, and takes its name from Sir P. H. Fleetwood by whom it was laid out, and who has erected various public buildings. It has a neat church, several chapels and schools, mechanics' institute, subscription news-room, market-house, lighthouse, docks, two wharfs, custom-house, and bonded warehouses. Steamers ply between it and Glasgow, Belfast, Londonderry, and Isle of Man. The number of vessels registered at the port on 31st December 1853 was 30 sailing vessels of 3804 tons, and 5 steamers of 904 tons; during that year 443 sailing vessels of 33,874 tons, and 672 steamers of 117,880, entered; and 268 sailing vessels of 19,255 tons, and 671 steamers of 118,725 tons left the port. Pop. (1851) 3048.

FLEETWOOD, CHARLES, lord-deputy of Ireland under the Commonwealth, and son-in-law of Cromwell, was one of the most prominent of the minor figures in that troubled period of English history. Entering the ranks of the parliamentary forces, he rose in 1644 to the rank of colonel of horse, and was appointed governor of Bristol in that same year. In the course of the civil wars that afterwards distracted the kingdom he distinguished himself, particularly at the battle of Worcester, and by his conduct on that occasion gained the favour of Cromwell and the whole army. After the death of his first wife he was pitched upon by Cromwell as a fitting husband for his eldest daughter Bridget, the widow of Ireton, and was appointed commander-in-chief of the forces in Ireland. Though the Protector did not place very much confidence in Fleetwood's attachment to himself, political motives afterwards induced him to nominate him one of the fourteen major-generals to whom the internal administration of the commonwealth was intrusted. On the death of the Lord Protector, Fleetwood did his best, by means of his influence with the troops, to supplant Richard Cromwell; but in the midst of his intrigues the nation recalled the exiled Stuarts. Fleetwood's prominent position marked him out as an object of vengeance to the restored king, and it was only with very great difficulty that he escaped with his life. Not long after the Restoration he died in wretchedness and obscurity at Stoke Newington, whither he had retired.

FLEETWOOD, *William*, a learned English bishop, descended of an ancient family in Lancashire, was born in the Tower of London, Jan. 21, 1656. He received his education at Eton, and at King's College, Cambridge. About the time of the Revolution he entered into holy orders, and having soon become a distinguished preacher, was appointed chaplain to King William and Queen Mary. By the interest of Dr Godolphin, vice-provost of Eton and residentiary of St Paul's, he was appointed rector of St Austin's, London, which is in the gift of the dean and chapter of St Paul's; and soon afterwards he also obtained the lectureship of St Dunstan's in the West. In 1691 he published his *Inscriptionum Antiquarum Sylloge*, in two parts; one containing remarkable pagan inscriptions, the other part ancient Christian monuments. In 1692 he published a translation of Jurieu's *Plain Method of Christian Devotion*, the twenty-seventh edition of which was printed in 1750. In 1701 appeared his *Essay on Miracles*, which called forth the animadversions of several writers, particularly Hoadly. In 1704 he published anonymously *The Reasonable Communicant*; and in 1705, *Sixteen Practical Discourses* on the relative duties of parents and children, husbands and wives, masters and servants, with three sermons on the case of self-murder. In the following year he was nominated to the see of St Asaph. In 1710 he published a vindication of the thirteenth chapter to the Romans, upon the authority of which the regal dignity had been so magnified by some as to make tyranny seem an ordinance of God, and to represent the most abject slavery as founded upon the principles of religion. This degrading doctrine was highly offensive to Bishop Fleetwood, who in this tract contends that, in the chapter referred to, St Paul requires of no people any more submission to the higher powers than that which is enjoined by the laws of their several countries. In 1712 he published Four Sermons, one on the death of Queen Mary in 1694, another on that of the Duke of Gloucester in 1700, a third on that of King William in 1701, and a fourth on the accession of Queen Anne; and also, the same year, an anonymous tract on Lay Baptism, according to the Church of England, a subject which then engaged a good deal of attention. *The Life and Miracles of St Wenefrede*, together with her Litanies, appeared in 1713, likewise without his name; the object of which was to expose the absurd superstitions by which weak minds are apt to be influenced, and, in particular, to show the delusions which had been practised under the names of pretended saints. In 1714 he was translated from the see of St Asaph to that of Ely, and continued there till his death, which took place at Tottenham, Middlesex, on the 4th of August 1723.

The remaining works of Bishop Fleetwood are these:—1. The Chancellor's Plea in the Divorce of Sir G. Downing, 1715; 2. Papists Not Excluded from the Throne on Account of Religion, 1717; 3. A Letter from Mr T. Burdett, Executed at Tyburn for the Murder of Captain Falkner, to some Attorneys' clerks of his acquaintance, 1717; 4. A Letter to an Inhabitant of the Parish of St Andrews, Holborn, about New Ceremonies in the Church, 1717; and 5. A Defence of Praying Before Sermon, as directed by the fifty-fifth canon. All these tracts, however, were published without the author's name. Bishop Fleetwood's character stood deservedly high in general estimation. His virtue was without any alloy of fanaticism, and his piety wholly untinctured with superstition. He was the friend of liberty and learning, equally zealous in defending the one and in encouraging the other. He assisted Dr Hickes in his great work *Linguarum veterum Septentrionalium Thesaurus*; and Hearne also confesses himself to have been under many obligations to him. In a professional point of view, he was unquestionably the best preacher of his time; and his occasional sermons exhibit a felicity of adaptation to the circumstances that had called them forth, which we should perhaps seek for in vain in similar compositions of that period. (J. B—E.)

FLEMISH LANGUAGE, that which is otherwise called *Low Dutch*, to distinguish it from the *German*, of which it is a corruption and a kind of dialect. It differs from the *Walloon*, which is a corruption of the French language.

FLEMISH SCHOOL. See PAINTING; and ARTS, § *Fine Arts*.

FLENSBORG, a seaport-town of Denmark, duchy of Sleswick, at the head of a fiord, about 16 miles from its mouth in the Baltic, and 20 N. by W. of Sleswick. Next to Copenhagen it is the most important commercial town in the Danish dominions. It has a number of vessels engaged in the West India trade and in the Greenland whale fishery: shipbuilding, with its collateral branches of industry, is carried on to a considerable extent; and there are extensive sugar-refineries, distilleries, soap-works, paper-mills, &c. It has one German and three Danish churches, three market-houses, a school of navigation, midwifery school, exchange, theatre, and public library. The churchyard is interesting as containing the remains of the Danish soldiers who fell in the battle of Istedt (25th July 1850). The government has placed a marble headstone at each grave—officers and common soldiers—with the same simple inscription on each, viz., after the name and rank, "fell at Idstedt." A railway has recently been opened connecting this town with Tonning. Pop. (including suburbs) about 18,000.

FLESH, a compound substance, consisting of the various softer solids of the animal body, and so denominated in contradistinction to bone. It consists chiefly of fibrin, with albumen, gelatine, extractive, phosphate of soda, phosphate

of ammonia, phosphate and carbonate of lime, and sulphate of potash. The general term flesh includes the muscles, fat, glands, &c., though sometimes it is restricted to muscle. See ANATOMY.

FLETA, an excellent Latin treatise on the entire body of the English law, by an anonymous author who lived in the time of Edward I., and wrote it during his confinement in the Fleet prison (hence Fleta).

FLETCHER, ANDREW, of Saltoun, a conspicuous political and social figure in Scotland during the latter half of the seventeenth century, was born in 1653 at Saltoun, in East Lothian, memorable also as the birth-place of Dunbar, the greatest of the old Scottish poets. The minister of the parish to whose care the education of the young Fletcher was intrusted was Gilbert Burnet, afterwards the celebrated bishop of Salisbury. It is not unlikely that from this preceptor Fletcher's mind received that political direction which he pursued in after life with such undeviating consistency. He certainly acquired, under Burnet's care, that knowledge of the Greek and Roman classics which afterwards supplied him with precedents for those political ideas which it was the main object of his life to realize in his native land. On reaching manhood Fletcher visited the Continent and spent several years in examining the laws and institutions of the leading European states. He then returned home, and in 1681 took his seat in the Scottish parliament as commissioner for the shire of East Lothian, and distinguished himself by the bitter and inflexible spirit in which he opposed the tyrannical tendencies of Charles the Second's government. Soon after he found it necessary to retire to Holland, at that time the general resort of all British political malcontents. In consequence of this step he was outlawed and his estate was confiscated. In 1683 he ventured over to England; but not being able to effect anything at that time, returned to the Continent, where he waited for two years till the Duke of Monmouth had completed his arrangements for a descent upon England. In this expedition Fletcher took part, but shortly after the landing at Lyme in Dorsetshire he had the misfortune to kill the mayor of that town in a quarrel, and was obliged in consequence once more to seek safety abroad. He fled to Spain; was there thrown into prison, from which he escaped in a manner (according to the traditionary accounts) savouring somewhat of the miraculous; and after a long pedestrian tour through that country passed into Hungary, where he joined the army as a volunteer, and distinguished himself by his daring and military capacity in the Turkish campaigns. On returning to the Hague he took an active part in forwarding the scheme of the English Revolution; and in 1688 returned to his native country. He immediately regained possession of his estate, and sat as a member, first in the Scottish Convention, and afterwards in the parliament. His intractable temper, and the jealousy with which he watched over the interests of Scotland, soon led him to oppose the government of William as stoutly and vehemently as he used to denounce and resist the encroachments of that monarch's two immediate predecessors. To the very last he held out against the Union of the two kingdoms; and when, very much to his chagrin, that measure was effected, he proposed in one of his works twelve *Limitations*, which he was strongly of opinion should be observed in the political relations of England and Scotland. Failing to secure the adoption of these, he retired from public life altogether, under the melancholy idea that he had survived not only his country's glory but her very existence as an independent nation. He died at London in 1716.

In a contemporary record, prefixed to one of the editions of his works, Fletcher is described as a "low thin man, of a brown complexion, with a stern, sour look, and fifty years old." The stern earnestness of his republicanism, according to this same writer, "made him oppose King Charles, invade King James, and oppose the giving so much power to King William, whom he never would serve; nor does he ever come into the administration of this Queen, but stands up a stout pillar for the constitution of the parliament of Scotland." On religious topics, however, it seems that his views were somewhat more liberal; for it is added, "His thoughts are large as to religion, and could never be brought within the bonds of any particular sect." His temper was so untractable as on many occasions to lead him to excesses utterly unwarrantable. One of the most notable instances of this was his murder of the mayor of Lyme, who merely attempted to remonstrate, when Fletcher, without asking leave, took possession of a horse belonging to that official, when he rode into Monmouth's camp with a view to aiding that adventurer in his attempt on the English crown. Less disastrous in its consequences, but equally characteristic, was Fletcher's conduct to Lord Stair, when he collared that nobleman, and threatened him with personal violence in the parliament house merely for letting drop a few words which Fletcher believed to reflect on him. To his political creed he adhered with unyielding consistency till his death, and, according to the testimony of Lockhart of Carnwath, "was so exceedingly wedded to his own opinions that there were few (and those, too, must be his beloved friends, and of whom he had a good opinion) he could endure to reason against him, and did for the most part so closely and unalterably adhere to what he advanced, which was frequently very singular, that he'd break with his party before he'd alter the least jot of his scheme and maxims." It is hard to decide whether his hatred of monarchical governments, or of England and the Union, was the most intense. Lockhart, however, believes that his aversion to the latter was so great that "in revenge to them he'd have sided with the royal family." He was, however, both by birth and temper, completely aristocratic in his tendencies, and it is said "liked, commended, and conversed with high-flying Tories more than any other set of men, acknowledging them to be the best countrymen and of most honour and integrity." Still, however, the general character both of his writings and of his political career was such as to entitle him to a high place among the advocates of British democracy. His personal character is absolutely free from every taint of meanness or dishonesty. In the words of Lockhart, "he hated and despised whatever was mean or unbecoming a gentleman, and was so steadfast to what he thought right that no hazard or advantage—not the universal empire nor the gold of America—could tempt him to yield or desert it."

Fletcher was a man of very considerable accomplishments. He was a complete master of the Latin, Greek, Italian, French, and Spanish tongues, and was well versed in history and civil law. His writings also in point of literary quality reach a high, sometimes even a remarkable, degree of excellence. The sagacity of his remarks, the freshness, energy, and occasional eloquence of his style, and the singular felicity of many isolated expressions, give a charm to his writings which compensates in a certain measure for the narrowness of view and illiberal bigotry with which they have been often charged. The most important of his works are —*A Discourse of Government with relation to Militias*, Edin., 1698; *Two Discourses concerning the affairs of Scotland*, Edin., 1698; *Discorso delle Cose di Spagna*, Napoli, 1698; *Speeches by a Member of the Parliament* which began at Edinburgh the 6th of May 1703, Edin., 1703; *An Account of a Conversation concerning a right regulation of Governments for the common good of Mankind*, Edin., 1704. In the last of these works, in which the interlocutors are Sir Edward Seymour, Sir Charles Musgrave, the Earl of Cromarty, and Fletcher himself, occurs for the first time in English literature the oft-quoted remark of the superiority of the national ballad-maker to the

national legislator. In the discourse on the affairs of Scotland a singular proposal is found, to the effect that the poor ought to be provided for by the resuscitation of a scheme of slavery such as the author believed to subsist among the ancient Greeks and Romans. The life of Fletcher was written in the style rather of a panegyrist than of a critical biographer by the late Earl of Buchan. His works, which in their original and detached form are now very rare, were collected and published in 1737, under the title of *The Political Works of Andrew Fletcher, Esq.*

(Earl of Buchan's *Essay on the Life and Writings of Fletcher of Saltoun;* Chambers's *Biog. Dict. of Eminent Scotsmen,* &c. &c.)

FLETCHER, *Giles* and *Phineas,* two celebrated religious poets of England, were the sons of Dr Giles Fletcher, English ambassador in 1558 at the court of Russia, and the cousins of the distinguished dramatist, John Fletcher.

Giles, the elder of the two brothers, was born about the year 1580; was educated at Trinity College, Cambridge; took orders in the Church of England, and died in 1623 at his living of Alderton in Suffolk. The only poem which he has left us consists of four several parts, joined together under the common title of "Christ's Victory and Triumphs." It is a kind of narrative of the redemption of man, reminding us to some extent of Milton's epic, and bearing, in form at least, a still more striking resemblance to that of Spenser. The animation of the narrative, the liveliness of the fancy, and the deep pathos that pervades the whole work, contribute to make it in its totality one of the most beautiful religious poems in any language, and, as Southey remarks, "will preserve the author's name while there is any praise." It has been complained that it abounds too much in allegory; and though this charge may be partly true, the interest of the poem is admirably maintained to the last. The work itself is written in a sort of variety of the Spenserian stanza, and its beauties are set in phraseology so marked and peculiar as to be readily recognised wherever quoted. This characteristic is still more striking from the antitheses and apparent paradoxes in which Fletcher delighted. Such lines as the following occur frequently throughout this poem:—

"The silence of the thought loud-speaking hears;"—
"The death of life, end of eternity;"—
"The obsequies of him that could not die."

Phineas, the younger brother of Giles, was born about 1584; entered King's College, Cambridge, in 1600; graduated there and took orders in the church, and in 1621 became vicar of Hilgay in Norfolk, where he died about 1660. His principal work—*The Purple Island; or, The Isle of Man*—is the nearest thing in English literature to an imitation of Spenser. It is confessedly an allegory, intended to symbolize all the functions of the human mind and body, especially the latter, and is quite unworthy of the fame it once enjoyed. It is wearisome throughout; and though it contains occasional passages of much beauty, it can hardly be said, on the whole, to repay perusal. Phineas Fletcher wrote, besides *The Purple Island,* some eclogues, a drama entitled *Sicelides,* and a poem in Latin hexameters, called *De Literatis antiquæ Britanniæ, præsertim qui doctrinâ claruerunt, quique collegia Cantabrigiæ fundârunt.*

FLETCHER, *John.* See BEAUMONT AND FLETCHER.

FLETEWOOD, WILLIAM, an English lawyer, and recorder of London in the reign of Elizabeth, was a natural son of Mr Fleetwood of Hesketh, in Lancashire. He was educated at Oxford, and studied law at the Middle Temple. In 1569 he was appointed recorder of London, and during his holding of this office he exercised his power very zealously against popish priests and their chapels. He was eminent as an orator and politician. As an author his chief works are—*An Oration,* spoken before the Lord Mayor at Guildhall; *A Table to Plowden's Reports; The Office of a Justice of the Peace,* 1658; *Annalium tam Regum Edwardi V., Richardi III., Henrici VII. quam Henrici VIII.; Titulorum ordine Alphabet. et Elenchus,* 1579 and 1597. He died in 1593.

FLEUR-DE-LIS, in *Heraldry,* a charge representing a lily, but conjectured to have originally been intended to represent the head of a javelin. The fleur-de-lis has been borne from a very early period in the royal arms of France.

FLEURY, ANDRÉ HERCULE DE, CARDINAL, the celebrated minister of Louis XV. of France, was born in 1653 at Lodève, in Languedoc. He was educated by the Jesuits at Paris, and became successively almoner to Marie Thérèse, queen of Louis XIV., in 1699 bishop of Frégus, and ultimately preceptor to the young prince, who afterwards succeeded to the French throne as Louis XV. On the death of the Regent Orleans in 1723, Fleury was made a member of the Council of State, and in 1726 (though at that time in his seventy-third year), was called to the office of prime-minister, which he held till his death in 1743. At the time when Fleury was called to the direction of affairs, the condition of France was truly deplorable. The nation was impoverished and worn out, and the exchequer emptied by the long wars of the Grand Monarque and the extravagances of the regent. Commerce was annihilated, public credit ruined, the government held in contempt, and the church distracted by internal dissensions. Fleury immediately set himself to reform these abuses, and by his honesty, economy, disinterestedness, and decision, effected very great reforms. Indeed the only reputable part of Louis the XV.'s reign was that in which the helm of state was guided by the hand of the aged cardinal. Though he was a confirmed friend to peaceful measures, he was twice driven by court intrigues to take part in foreign wars; first, in the case of Stanislaus Leczinsky, the dethroned king of Poland, whose daughter Louis had married; and afterwards in that of the Austrian succession, of which he did not live to see the end. One of the most useful acts of Fleury's administration was the completion of the Royal (now the Imperial) library, which he enriched with many valuable manuscripts, chiefly in the oriental languages.

FLEURY, *Claude, Abbé,* was born at Paris, December 6, 1640. Destined for the bar by his father, he was placed at the college of Clermont (now that of Louis-le-Grand), where the sons of the first families of France were educated. After passing brilliantly through the regular collegiate studies, he was nominated an advocate to the parliament of Paris in 1658, and continued during nine years to pursue the legal profession. Feeling a strong desire to enter the church, being fond of solitude, but especially influenced by the religious sentiments which he had imbibed during his early education, he renounced the law, which, with history and literature, up to this time had formed the principal objects of his study, in order to devote himself to theology exclusively. He had already been some time in holy orders, when Louis XIV., in 1672, selected him as tutor of the princes of Conti; and so well did he acquit himself in this office that the king intrusted to him afterwards the education of the Count of Vermandois, one of his natural sons; and at the death of the young prince, Fleury received as recompence for his services the abbey of Loc-Dieu, in the diocese of Rhodez. Five years after this he was appointed sub-preceptor of the dukes of Burgundy, of Anjou, and of Berri. He thus became intimately associated with Fénélon, the chief preceptor of his royal pupils. In 1696 he was selected to fill the place of La Bruyère in the French academy; and on the completion of the education of the young princes, the king bestowed upon him the rich priory of Argenteuil, in the diocese of Paris. On assuming this benefice he resigned that of the abbey of Loc-Dieu, thus setting an example of rare disinterestedness. It was about this time that he decided, according to the suggestions of his friends, on commencing his great work, for which he

had long been collecting materials—the *Histoire Ecclésiastique.* Hitherto France did not possess any work of equal merit in this department of literature. There existed many works more or less voluminous on matters of doctrine and discipline, but no one had written a history of the church—a complete and scientific exposition of the progress of Christian society, of its organization and its primitive doctrine, of its varied changes in connection with the state, of the successive development of its institutions, of all the modifications introduced into its symbols and its rites. Of this great work the French say: "One work only was wanting at that time which should collect together the scattered information of the epoch, and that was the very time to publish it." Fleury had evidently the intention of writing a history of the church for all classes of society; but at the time in which his great work appeared it was less religion than theology that absorbed the attention of the clergy; and his work, as well as all those that had been published previously, is more a work for the student than one for the people, dwelling as it does very particularly on questions of doctrine, of discipline, of supremacy, and of rivalry between the priesthood and the imperial power, while it notices very slightly general questions affecting religion and morality. Notwithstanding all this, the success of the *Histoire Ecclésiastique* was very great. The first edition, printed at Paris, in 20 volumes 4to, 1691, was followed by many others, among which may be mentioned that of Brussels, in 32 vols. 8vo, 1692, and that of Nismes, in 25 vols. 8vo, 1778 to 1780. The work of Fleury only comes down to the year 1414. It was continued by T. Claude Fabre down to 1698, in 16 vols. 4to, and thence by Alexandre Lacroix down to 1778. These supplementary continuations are very inferior to the labours of Fleury; they are mere compilations of facts, with little criticism, and still less talent. In consulting the work of Fleury and its supplements the general table of contents, published by Rondel, Paris, 1758, 1 vol. 4to, will be found very useful. Translations have been made of the entire work into Latin, German, and Italian.

Fleury has left other works, though not at all so celebrated. These are *Mœurs des Chrétiens*, Paris, 1662; and *Mœurs des Israélites*, Paris, 1772—two works at first published separately, but afterwards united and published in 3 volumes 12mo, written with elegance and precision; *Catéchism Historique*, first published in 1679, 12mo; *L'Institution au droit Ecclésiastique*, Paris, 1687: besides several minor works of little importance.

FLEURUS, a small town of Belgium, province of Hainault, 7 miles N.E. of Charleroy, and remarkable for the battles fought there in 1622, 1690, 1794, and 1815. Pop. (1851) 3483.

FLEXOR, in *Anatomy*, a name applied to several muscles, whose office is to bend the parts to which they belong; in opposition to the *extensors.*

FLINDERS, MATTHEW, a distinguished English navigator, was born at Donington, in Lincolnshire, in 1760. After serving in a variety of subordinate capacities, he was commissioned by the English government in 1801 to circumnavigate and explore New Holland, to our knowledge of which country he contributed more than any other discoverer of that day. He underwent the most dreadful hardships and successfully braved the greatest dangers in the course of this expedition. On his way home he was driven by stress of weather to Mauritius, where he was seized by the French authorities, and detained in confinement for six years. Reaching home at length in 1810, he began to prepare for press the narrative of his voyage and adventures. This work was published in 1814 (on the very day on which its author died), under the title of *A Voyage to Terra Australia, &c., in the years* 1801, 1802, *and* 1803, *in H.M. ship Investigator, and subsequently in the armed vessel Porpoise, and Cumberland schooner,* in two vols., with Atlas. For a detailed account of his discoveries, see art. AUSTRALIA, vol. iv., pp. 253–4.

FLINT, silicious mineral. See MINERALOGY. It consists of 98 silica, 0·50 lime, 0·25 alumina, 0·25 oxide of iron, and 1·0 loss. This mineral occurs of various colours, but generally yellowish or dark gray, and usually in a compact amorphous body, of various shapes. It is widely dispersed over the world, occurring chiefly in the chalk formations, but especially in limestone. Its principal use is for gun-flints, and for striking light with steel; and it also forms, when reduced to powder, an ingredient in procelain and glass. The manufacture of gun-flints is very simple, and is performed with an iron mallet and chisel. A dexterous workman will make 1000 in a day.

FLINT-GLASS. See GLASS-MAKING.

FLINT (Welsh *Fflint. Tegcingl*), the capital of the county of the same name, a market, borough, and seaport town, N. Wales, 173 miles N.W. from London, situated on the south shore of the estuary of the Dee, on the narrow strip of flat land lying between the sea and the hills of the inland parts of the county. The houses are for the most part well built, but the place has altogether an air of decay. The harbour and wharfs have been lately much extended; but the accumulation of sand is so great that there is little or no prospect of any important increase of shipping. The principal exports are coals, lead in a manufactured state, and iron. Ship-building is carried on to some extent in the smaller description of vessels. The town possesses a handsome Gothic church, and five chapels belonging to the different Dissenting bodies. There are also a guildhall and county jail, and handsome schools.

Close by the shore stands the ruins of the ancient castle of Flint. It is said to have been built by Edward I.; and it was here that Percy delivered Richard II. to Bolingbroke. It was dismantled by order of the House of Commons in the time of the civil wars in 1646.

The borough along with Caergwrle, Caerwys, Overton, and Rhyddlan, returned one member to parliament from 1536 to 1832; since the latter period Holywell, Mold, and St Asaph have been added as contributing boroughs; constituency in 1852, 817. The political influence is chiefly in the hands of Lord Mostyn. Population in 1851, 3296; inhabited houses, 693. The assizes are now held at Mold.

FLINTSHIRE (Welsh, *Sir Fflint*), a maritime county in North Wales. This county is made up of two separate portions lying at a distance of 8 miles from each other. The main portion is bounded on the N. by the estuary of the Dee; on the N.E. and E. by Cheshire; and on all other sides by the county of Denbigh. Its greatest length is from S.E. to N.W. about 26 miles, and its breadth is about 12 miles. The detached and smaller portion of this county lies to the S.E. It is bounded on the N. by Cheshire; on the E. and S. by Shropshire; and on the W. by Denbighshire. It is about 9 miles long by 5 broad. The whole of the county possesses an area of 289 square miles or 184,905 acres, and it is the smallest of the Welsh counties. The origin of the name is involved in obscurity. The greater part of this county is situated on the coal measures, and the other members of the group of carboniferous rocks. The northern rim of the North Wales coal-field extends along nearly the whole of its northern boundary. Along the southern edge of the coal strata the millstone grit extends in a continuous line, which, further south, is followed by the carboniferous or mountain limestone; and in the extreme south by the upper Silurian (Wenlock) rocks. The eastern as well as the western extremities of the main portion of the county, and also the whole of the detached part, are situated on the new red-sandstone formation.

Along the southern boundary the Wenlock rocks rise into a mountain chain of considerable elevation, forming the northern limb of the Berwen range; and terminating about

Flintshire.

a mile from the shore of the Dee, near the western extremity of the county. The small portion of land lying still further west is flat, and much of it consists of rich alluvium embracing a portion of the well-known Rhyddlan marsh, and forming part of the celebrated Vale of Clwyd (see DENBIGHSHIRE). The watershed of the Berwens forms the county boundary for a considerable distance along the south; and the summit of a member of this range, the Moel Fammau, common to this county and Denbighshire, rises to the height of 1845 feet. The general character of the county is mountainous, although the hills, with the exception of those already mentioned, do not rise to any great elevation. Besides the tract of flat rich land on the extreme west, there is a similar tract of no great extent in the same geological formation in the east; and from the one to the other there extends along the southern shore of the Dee a narrow strip of rich alluvial soil. The detached portion of the county is also flat.

Some of the small valleys are very beautiful, although not equal to those of other parts of North Wales. With the exception of that part of the vale of Clwyd embraced by this county, the vale of the Alyn is the most important.

The principal rivers are—the Dee, forming part of the northern boundary of the main part of the county, and also the eastern boundary of the detached portion; the Clwyd, which forms the western boundary for about 3 miles; the Elwy, which enters the county near the city of St Asaph in the west, and after joining the Clwyd falls into the sea at Rhyl; and the Alyn, which, rising in the Berwens, near the eastern extremity of the county, after a very tortuous course, flowing first west and then east, is discharged into the Dee, after traversing part of Denbighshire.

Flint possesses few lakes, and these are small and unimportant. The principal ones are Llyn Helyg in the N.W., and Llyn Cyffynwy in the S.E.

Owing to its proximity to the sea the climate is for the most part mild; although, of course, on the Berwens and other elevated land the air is keen. The cultivated crops consist of wheat, beans, oats, barley, Welsh bere, rye, vetches, pease, hay, potatoes, turnips, mangold-wurtzel, and carrots. Clover seed is also grown, but not to any great extent. The eastern part of the county is liable to be flooded by the overflowings of the Dee, and is mostly in pasture. The farms are of considerable size, and the farmers are more intelligent than in most other parts of Wales. Agriculture is therefore in a more advanced state. In addition to the crops, already mentioned, there is a good deal of cheese and butter made; there is also a very considerable production of mutton and beef, for which a ready market is found among the thickly planted mining population. Wool and oak bark as well as timber are produced to a considerable extent, but it is for its mineral wealth and manufacturing industry that the county of Flint is chiefly remarkable. In addition to its numerous coal mines and limestone quarries, it contains some of the richest lead and calamine mines in the British islands, and large quantities of carbonate of baryta have been lately found there. There are numerous smelting works; and at those at Bagillt a very large proportion of all the lead ore raised in the world is smelted, and has the silver separated from it. There is a very extensive foundry and engine manufactory at Mold; and there are numerous iron, chemical, coarse pottery, and other works scattered all over the more accessible parts of the county, and giving employment to a very large number of work-people. The shipping trade is not extensive, for, owing to the gradual silting up of the Dee, only vessels of light draught can enter the Flintshire ports.

The lower parts of Flintshire are well supplied with means of communication and transport, for, in addition to the water carriage on the Dee, extending the whole length of the country, the Chester and Holyhead railway traverses its greatest length, and the Chester and Mold railway penetrates to the centre, and opens up a communication with all parts by means of the valley of the Alyn.

Flip ‖ Flodden Field.

The principal towns are Flint, Mold, St Asaph, Rhyl, and Holywell; besides which there are several smaller ones, the principal of which are Rhyddlan, Hawarden, Caergwrle, Caerwys, and Overton. The county is divided into 28 parishes, and is for the most part in the diocese of St Asaph. It returns one member to parliament, and has done so since 1536. The political influence is almost entirely in the hands of Lord Mostyn, and the political opinions are chiefly of a liberal tendency; constituency in 1852, 2912. The average gross rental of the county is as high as 24s. 9d. per acre. The annual value of real property paying income tax in 1851 was L.399,261, and of property assessed to the relief of the poor in 1850, L.222, 16s.

The population of the county by the census of 1851 was 68,156, giving an average of 235 persons to a square mile, or 2·7 acres to a person. Of the total numbers 34,452 were males, and 33,704 females. Flint is thus, next to Glamorgan, the most densely peopled county in Wales, and contains rather more than four times as many people to an acre as Radnor, the most thinly peopled of the Welsh counties. The number of inhabited houses was 14,041, uninhabited 798, building 80, giving an average of 49 houses to a square mile, and 4·8 persons to a house. The following table gives the census returns for the last fifty years:—

Years						Increase of Population per cent. in Fifty Years.
1801.	1811.	1821.	1831.	1841.	1851.	
39,469	45,937	53,893	60,244	66,919	68,156	72

It is calculated that about eight per cent. of the population live by agriculture, and nine per cent. by trade, manufactures, &c. About one-fourth of the whole are in the condition of labourers, servants, &c. About thirteen hundred persons possess independent means, and five hundred follow professions.

In 1847 the total number of children of the working classes at day schools within the county was 7586. Of schools 60 were church or "national" schools, with 4893 scholars; 1 Calvinistic Methodist, with 48 scholars; 2 Independent, with 103 scholars; 2 Roman Catholic, with 55 scholars; 5 British and Foreign, with 806 scholars; 5 of no denomination, with 311 scholars; 2 workhouse schools, with 112 scholars; 1 factory school, with 30 scholars; and 53 private adventure, with 1228 scholars. It appears that the average annual income of the teachers from all sources was only L.25, 5s. 10d. The total number of Sunday schools was 133, with 15,310 scholars. Of these 26 were Church, with 3841 scholars; 2 Baptist, with 161 scholars; 43 Calvinistic Methodist, with 5092 scholars; 27 Independents, with 2377 scholars; 34 Wesleyan Methodist, with 3779 scholars; 1 of other denominations, with 60 scholars. In 51 of these schools instruction was given in the Welsh language only; in 18 in the English language only; in 62 in both languages; and in two, which language was not ascertained. A great proportion of the population use the English language, and, as may be supposed, from the proximity to England, and the great industrial progress of this county, the manners and habits approach more nearly to the English type than in most other parts of Wales.

There are numerous fine gentlemen's seats throughout this county; and there is a cathedral and bishop's palace at St Asaph. (J. G—W—D.)

FLIP, a mixed drink composed of malt liquor, brandy, and sugar, and esteemed among sailors.

FLODDEN FIELD, in the county of Northumberland, eight miles S.E. of Coldstream, is memorable as the scene of the battle fought there on 9th September 1513 between the

English under the Earl of Surrey and the Scotch commanded by James IV., in which the latter were totally defeated and their king slain. See SCOTLAND.

FLOOD. See DELUGE.

FLOOR, in building. See BUILDING. Boards for flooring may be prepared with great despatch by means of the *flooring-machine*, by which the several operations of sawing, planing, grooving, and tonguing, are all carried on at the same time by a series of saws, planes, and revolving chisels.

FLORA, in *Roman Antiquity*, the goddess of flowers. There is an old tradition extant in the Latin classics to the effect that Flora was originally a courtezan, who amassed a large fortune, which she bequeathed to the Roman people on condition of being annually commemorated in a festival. Her worship, however, dates from a very remote period, as it is recorded that Tatius built in her honour a temple, for the service of which a special flamen was consecrated by Numa. The temple of Flora was situated near the Circus Maximus. Flora is commonly represented as a woman in the very prime of life, bearing in her left hand a cornucopia filled to overflowing with flowers of every kind.

FLORA, in *Botany*, denotes a catalogue or account of flowers or plants.

FLORALES LUDI, or FLORALIA, in *Roman Antiquity*, a festival in honour of Flora, which lasted for five days, from April 28 to May 2. It is said to have been instituted in the year 238 B.C., and to have been afterwards discontinued in consequence of the license and immorality to which it gave occasion. In the year 173 B.C., however, it was restored at the command of the senate, as the blossoms had suffered very severely in the spring of that year from the severity of the weather. The ædiles, as usual, presided over these games, which consisted chiefly in the exhibition of mimic fights and indecent dances performed by women of loose character, who used also to throw beans and chick-peas among the crowd. Instead of wild beasts, hares and rabbits were let into the arena, and chased about for the public amusement. The spot where the Floralia were held is still called the *Campo di Fiora*, and at this day forms one of the squares of Rome, and is used as a market-place.

Festivals very like the floralia are still celebrated throughout Italy, where they have always been very popular. Floral games, or *jeux floraux*, was the name given to the reunions held in the south of France, especially at Toulouse, where garlands of flowers were awarded as prizes to successful competitors in the poetical contests.

FLORENCE, (Italian *Firenze*, and in old writers *Fiorenza*,) a famous city of Italy, capital of the grand duchy of Tuscany, is situated on the river Arno, which divides it into two unequal parts. The important place which this city occupies in history, the beauty of its situation, the treasures of art which it contains, all contribute to its interest and celebrity.

"Girt by her theatre of hills, she reaps
Her corn, and wine and oil, and Plenty leaps
To laughing life, with her redundant horn.
Along the banks, where smiling Arno sweeps,
Was modern Luxury of Commerce born,
And buried learning rose redeemed to a new morn."

Childe Harold, Canto iv., 48.

The origin of Florence is not clearly ascertained; but it probably owes its rise to the establishment of a Roman colony here by Octavianus after the victory of Perusia, though there seems some reason to believe that one had been established here about 40 years previously by Sulla. The only important notice of Florence to be met with in the ancient writers is in Tacitus, *Annal.* i. 79, where it is mentioned among the municipia which, in the reign of Tiberius, sent deputies to Rome to remonstrate against the intended diversion of the course of the Clanis into the Arnus, by which their town and territory would have been rendered liable to inundations. The only remains of the Roman period are some relics of an amphitheatre near the church of Santa Croce, and a few inscriptions. In 406 Florence was besieged by the Goths under Radagaisus and reduced to the last extremity, till the arrival of Stilicho with an army, who defeated the barbarians and relieved the town. It was almost entirely destroyed by Totila, king of the Goths, in 541, and remained in ruins and obscurity till the end of the eighth century, when it was rebuilt by Charlemagne after that monarch had conquered the Lombards. From this time it rose rapidly into importance, and at length assumed a republican form of government. During the fourteenth and fifteenth centuries it was one of the most opulent cities in Europe; and from the many eminent and learned men who flourished here, under the patronage of the Medici family, at a time when the great nations of Europe were only beginning to emerge into civilized existence, it has justly acquired the designation of "Etruscan Athens." See ITALY, TUSCANY, &c.

The city of Florence is situated in the fertile and well-wooded *Valdarno*, or vale of the Arno, encircled by the Apennines. The magnificent and stately character of many of its buildings, the numerous bright villas scattered about the vale and on the slopes of the hills, and the fine forms of the mountains which inclose the prospect, have earned for it the title of *Firenze la Bella*. Behind the city rise hills covered with olive and fig trees and other plants, natives of warmer climates; beyond are chestnut-covered mountains; while in the distance the naked and rugged summits of the lofty Apennines rise to the height of more than 3000 feet above the plain. The city extends along both banks of the Arno, which intersects it from S.E. to N.W. Its form is that of an irregular pentagon, of which the greater portion is on the right or northern side of the river. It is inclosed by old walls nearly six miles in circuit and pierced by eight gates. They are still unbroken, except where the citadels of Belvedere and the *Fortezza da Basso* have been inserted, but are totally useless as a means of defence; and the towers which ornamented their circuit have generally been demolished or lowered to the level of the curtain. That portion of the Arno within the walls is crossed by four bridges, the finest of which is the Santa Trinitâ, adorned with statues, and having a central arch of 95 feet span. Beyond the walls, on each side, was a suspension bridge, but one of these was carried away by the great flood of 1844. In the central or older portion of the town the streets are generally narrow and irregular, but in the more modern parts they are wide, straight, and well paved. Florence contains a great number of magnificent edifices and squares, generally adorned with statues, columns, or fountains. First among its public buildings is the cathedral, commenced by Arnolfo in the end of the thirteenth century, and completed in the fifteenth by Brunelleschi. It is 454 feet in length; the transept is 334 feet long; height of nave 153, and of side aisles $96\frac{1}{2}$ feet. The magnificent cupola by Brunelleschi excited the admiration of Michael Angelo, and is said to have served him as a model for that of St Peter's at Rome. It is of an octagonal form, 384 feet high, and $138\frac{1}{2}$ in diameter. The interior of the building is rather dark from the smallness of the windows, and the deep and rich colours of the stained glass with which they are filled. The exterior is almost entirely cased in marble, and the pavement is tesselated with red, blue, and white marble. Detached from the cathedral, and like it cased in marble, is the belfry, a light and elegant tower 276 feet in height. In front of the principal entrance of the cathedral stands the baptistery of St John, an elegant octagonal building. These, like most of the other churches and public buildings, are richly adorned with works of art. The church of Santa Croce, called the Pantheon of Florence, is interesting from the number of sepulchral monuments which it contains; among

which are those of Michael Angelo, Galileo, Machiavelli, and Alfieri. The church of San Lorenzo, built by Brunelleschi, contains the mausoleum of the Medici family. Annexed to it is the building begun by Michael Angelo and finished by Vasari, containing the Laurentian library, of above 120,000 volumes, and a valuable collection of MSS. amounting to more than 9000. The *Palazzo Vecchio*, now occupied by government offices, is a square massive-looking structure, surmounted by a tower 268 feet in height. The *Palazzo Pitti*, the residence of the grand duke, is enriched by numerous fine statues, busts, and paintings, and has a library of 70,000 volumes and 1500 MSS. Attached to it are the extensive gardens of Boboli, laid out in rectangular walks flanked with cut trees, and having terraces, statues, and fountains. Connected with these gardens is a botanical garden, a museum of natural history, an anatomical collection modelled in wax, and a fine library. The Palazzo Riccardi is used partly for government and partly for literary purposes, and contains a library of about 20,600 volumes and 3600 MSS. The Magliabechi, a library in the *Uffizi*, obtains a copy of every book published in the Tuscan states, and contains upwards of 150,000 volumes and 12,000 MSS. The Marucellian library contains about 50,000 volumes. The *Uffizi*, erected after a design of Vasari by Cosmo I., forms three sides of a parallelogram. In the upper floor of this building is the celebrated Florentine gallery, one of the richest existing collections in sculptures, medals, bronzes, paintings, and other works of art. Among its statuary is the famed *Venus de'Medici*, discovered in the sixteenth century in the Villa Hadriana, near Tivoli. The whole of the left arm and part of the right are modern, having been restored by Bandinelli. The collection of paintings comprises superb specimens of all the best schools, and is said to surpass even that of the Vatican. Florence contains no fewer than 170 churches, 89 convents, 2 ducal and many other palaces, 12 hospitals, and 8 great and small theatres. The literary and educational institutions are numerous and important. Chief among these is the academy *Della Crusca*, established in 1582, to which is united the University of Florence, founded in 1438. Its grand object is the sifting or purifying of the Italian language, and hence its name *Crusca*, chaff, or husk of corn. There are also academies of the fine arts and of agriculture, a medico-chirurgical college, an athenæum, and a number of other literary societies. The charitable institutions are numerous and varied, including asylums for the deaf and dumb, blind, orphans, and an association of the higher classes for ministering to the necessities of the sick and infirm poor. The inhabitants of Florence are industrious, cheerful, and hospitable. The chief manufactures are silks, straw-hats, carpets, porcelain, mosaic work, perfumery, and jewellery. The salubrity and beauty of the town and neighbourhood; its libraries, reading-rooms, and collections in the fine arts; its mild and liberal government; and the moderate price of provisions, render this the most pleasant place of residence in Italy, and have attracted to it a great number of English families. It has produced many individuals eminent in arts, science, and literature: among others, Machiavelli the political writer; Dante Allighieri, Luigi Rucellai, Menzini, and Filicaja, poets; Guicciardini the historian, Michael Angelo Buonarotti the artist, Galileo the astronomer, Amerigo Vespuccio the navigator, Lulli the musician, and the artists of the school of this city. Florence is situated N. Lat. 43. 46. 41., E. Long. 11. 15. 55., and is 182 from Genoa, 186 from Venice, 72 from Bologna, 53 from Pisa, 41 from Siena, and 190 from Rome. It is connected by railways with Pistoja, Pisa, and Siena. Pop. (1854) 115,675.

FLORENCE, an ancient English gold piece coined by Edward III., of six shillings sterling value.

FLORES or FLORIS, an island in the Indian Archipelago, about 200 miles in length, and 42 to 50 in extreme breadth, lying between E. Long. 119. 55. and 123., and S. Lat. 7. and 9. 5. The surface is hilly, particularly towards the south, where there are several high volcanic mountains, but the interior is very imperfectly known. The principal port, Endé, on the south has an excellent harbour. The chief products are cotton, rice, sulphur, saltpetre, sandalwood, bees'-wax, horses, and slaves; and its trade is carried on principally with Singapore. The native inhabitants are Timuri, but the coasts are chiefly inhabited by Bugis and Malays. The Dutch have a fort on the N. coast called Pota. Flores gives name to the strait which separates it on the E. from Solor and Adenar. This is also the name of one of the Azores. See AZORES.

FLORIAN, JEAN PIERRE CLARIS DE, was born in 1755 at the Château of Florian, near Sauve, in Languedoc. His uncle, who had married a niece of Voltaire, introduced him on one occasion to that philosopher in his retreat at Ferney, and the young Florian remained with the dictator of French literature till his fifteenth year. In 1768 he attached himself to the Duc de Penthièvre, who first of all gave him a commission in a dragoon regiment, and afterwards made him one of his own gentlemen in ordinary. In 1783 Florian produced his first work *Galatée*, a professed imitation of the *Galatea* of Cervantes, which was followed two years later by his *Numa Pompilius*, an equally undisguised imitation of the *Télémaque* of Fénélon. In 1788 appeared *Estelle*, a pastoral romance, bearing a strong general resemblance to the *Galatée*, but esteemed superior to that, and indeed to most of the author's other works. In 1791 appeared his romance of *Gonzalve de Cordoue*, which, as well as the prefatory history of the Moors, was warmly commended. But Florian's chef-d'œuvre is his collection of fables, the best beyond a doubt that has appeared in France since the days of La Fontaine. On the breaking out of the French Revolution, Florian retired to Sceaux, where, however, he was soon discovered and dragged to prison by the Parisian sans-culottes. During his confinement he wrote *Guillaume Tell*, the weakest production of his mind. His imprisonment was not of long duration, but it injured his health so materially that he only survived his release by a few months. Florian died September 13, 1794, having just reached his fortieth year. After his death appeared his translation or rather his trashy abridgment of *Don Quixote*, which has been much censured for its want of humour. The best collective edition of Florian's works is that of 1812, in 16 vols. 18mo.

FLORIDA, one of the most southern of the United States of North America, is a peninsula stretching far into the Gulf of Mexico, and to the Atlantic Ocean, comprised between the parallels of 25. and 31. N. latitude, and the meridians of 80. and 87. 35. W. longitude. It is 350 miles in length, and from 50 to 250 in breadth, containing 59,268 square miles. Florida is bounded on the N. by Alabama and Georgia, E. by the Atlantic Ocean, S. and W. by the Gulf of Mexico. During the greater part of the sixteenth century, however, the southern part of the eastern coast of North America was comprehended under the name of Florida; and in 1763, when ceded to Great Britain by Spain, it extended as far W. as the Mississippi, the northern boundary being the St Mary's river, from the ocean to its source, thence by a right line to the junction of the Flint and Appalachicola rivers, thence up the Appalachicola to the parallel of 31. N., and thence due W. on that parallel to the Mississippi river. That portion lying between the Mississippi and Perdido rivers is now included in the states of Lousiana, Mississippi, and Alabama, while that part lying E. of the Perdido is in Florida.

It is now generally conceded that Florida was first discovered in 1497 by Sebastian Cabot, a Venetian in the English service, whence a right to it was claimed by the English; and it was included with Georgia in the charter

Florida. granted by Charles II. to Carolina. In 1512 it was more fully explored by Juan Ponce de Leon, a companion of Columbus in his second voyage. He embarked from Porto Rico March 3, 1512, with three ships fitted out at his own expense. On Easter Sunday, called by the Spaniards "Pascua Florida," land was seen, to which he gave the name Florida. He was subsequently appointed governor, and attempted, in 1521, to colonize the newly discovered land; but he was attacked by the Indians, many of his men were killed, and he himself mortally wounded.

In May 1539, Hernando de Soto arrived in the bay of Spiritu Santo, and passed across the country to the Mississippi. In February 1562 the French Calvinists sent an expedition under the command of Ribault, who discovered the St John's River; and taking formal possession of the continent, left a small colony on Lemon Island, while he returned to France. The colonists were hospitably received by the natives, but suffered many hardships, and were on the point of abandoning their settlement when Ribault again arrived from France, bringing supplies and reinforcements.

But the Spaniards, who not yet renounced their claim, actuated by jealousy against the Calvinists, sent an expedition under Pedro Melendez, who arrived in August 1565, and on the 4th day of September attacked and captured the French, who were all hanged on trees, with the inscription "not as Frenchmen, but as heretics." Three days afterwards the Spaniards landed in the harbour of St Augustine, on the Atlantic coast, and laid the foundation of that town, which is the oldest, by more than forty years, in the United States. Houses in it are yet standing which are said to have been built before Virginia was colonized.

In 1586, St Augustine was taken and pillaged by Sir Francis Drake. In 1597 the French, under Dominic de Gourges attacked and defeated the Spaniards, and, by way of retaliation, hung their prisoners on trees, with the inscription, "not as Spaniards, but as assassins."

In 1702 Col. Moore besieged the town for three months; but the Spaniards coming to its relief, he was obliged to retreat. Another attempt was made in 1740 by General Oglethorpe of Georgia to take St Augustine, but without success. In 1763 Florida was ceded to Great Britain by Spain, who received Havana in exchange. The British government subsequently gave great encouragement to agriculture, and numerous colonists poured into the country from various parts of Europe, and the settlements were in a most flourishing condition. It was, however, by a well-concerted scheme of the Spaniards, recaptured in 1781, and guaranteed to them in the peace of 1783. In 1821 Spain ceded the Floridas to the United States, and in July following it was, in behalf of the latter, formally occupied by General Andrew Jackson. Since its acquisition by the United States, Florida has been the seat of many sanguinary conflicts with the Seminoli Indians, led on by their daring chief Osceola. The savages, although a mere handful, managed to baffle for seven years the United States soldiers, by retreating to their swamps; and before they were finally subdued, in 1842, the expense to government was many millions of dollars. In 1846 the greater part of the tribe was removed beyond the Mississippi river, in pursuance of a treaty made with the U.S. government. In 1838 a state constitution was adopted preparatory to admission into the Union, which, however, was not consummated until March 3, 1845.

The executive power in Florida is vested in a governor elected by the people for four years, and receiving a salary of $1500 a-year. The legislative power is in the hands of a senate of 19 members elected biennially, and a house of representatives of 40 members, elected annually, and both by popular vote. The judiciary consists, 1st, of a supreme court composed of a chief and two associate judges, who hold four sessions annually, one in each of the following places—Tallahassee, Jacksonville, Tampa, and Marianna; and, 2d, of four circuit courts. Florida has but one member in the House of Representatives, and three electoral votes for the president. The assessed value of property in 1850 was $22,784,837, ordinary expenses, $45,000 per annum.

Chief towns—Tallahassee, pop. 1391; Jacksonville, pop. 1045. Tallahassee is the capital. Florida is generally level, probably never elevated more than 250 or 300 feet above the sea. The southern part of the peninsula is covered with large sheets of water called the *Ever-glades*, of immense extent, and filled with islands, and which, it is supposed, may be rendered available by drainage. The central portion of the peninsula is somewhat elevated, the highest point being 170 feet above the level of the ocean, and gradually declining towards the coast on each side.

Bays and rivers. The western coast of the state has a number of bays, viz., Chatham, Charlotte Harbour, Tampa, Appalachee, Appalachicola, Choctawatchee, and Pensacola bays. The last affords an excellent harbour. There is also a chain of lakes running through the middle of the state, the largest and most southern of which is Lake Okechobee. The rivers are numerous, and are navigable for second-class vessels. In the N.W. is the Perdido, a small river separating Florida from Alabama, followed in order by the Escambia, the Blackwater, the Yellow-water, the Choctawatchee, and the Chipola, but none of great length; and all entering from the state of Alabama, discharge their waters in the Gulf of Mexico, with the exception of the Chipola, an affluent of the Appalachicola, which last also flows through Florida.

The rivers flowing into the Atlantic are the St Mary's (dividing Florida from Georgia), the St John's river, and Indian river. The St John's is navigable for 100 miles by vessels drawing 8 feet water. Among the other rivers on the western coast of Florida may be mentioned the Ocklockonee, the Suwanee, the Amasura, and the Charlotte.

Soil and productions. The soil of this state is generally sandy, except in the hummocks, where it is mixed with clay; yet, owing to the mild climate, it is highly productive in many parts. The best lands, however, of the state lie useless at present for want of drainage, and can be had at $5 or $10 per acre. Florida is particularly well adapted for grazing. The number of farms in Florida in 1850 was 4304, containing 349,049 acres of improved land, and yielding 1,996,809 bushels of Indian corn, 66,586 of oats, 135,359 of peas and beans, 757,226 of sweet potatoes, 1,075,090 lbs. of rice, 998,614 lbs. of tobacco, 18,052,400 lbs. of cotton, 23,247 lbs. of wool, 371,498 lbs. of butter, 18,015 lbs. of cheese, 2510 tons of hay, and 2,750,000 lbs. of sugar; live stock valued at $2,880,058, and slaughtered animals $514,685.

Florida exports about 80,000 to 100,000 bales of cotton annually. The capacity and production, &c., may be stated as follows for the year 1854:

Number of bales of 400 lbs. produced	90,000
Labourers employed	23,000
Acres in cultivation	175,000

Florida abounds in forest trees, among which are the live oak (highly esteemed for ship-building), and other varieties of oak, swamp cypress, pine, hickory, magnolia, dogwood, and laurel. The *Palma christi* or castor-oil bean here becomes a large tree. On the islands and keys box-wood, satin-wood, mastic, and lignumvitæ, abound; arrowroot grows wild, and ginger and cinnamon are easily cultivated. The pine grows in that portion of the state near Indian river. Fruit trees in great variety find a congenial soil and climate in Florida (except in a few seasons of unusual severity). The lime, lemon, orange, olive, cocoa-nut, plantain, pine-apple, banana, guava, citron, pimento, coffee, pepper, cloves, &c., may all be successfully cultivated.

Manufactures. Florida is not a manufacturing state. There were in 1850 but 121 establishments, producing annually $500 and upwards. Of these, the cotton factories employed 28 males;

Florin ‖ Florus.

flour and grist mills, 14; saw and planing mills, 489; turpentine making, 75; tanning and currying, 12; brick making, 97. Value of home-made manufactures, $75,582.

Very little progress has been made in works of internal communication, nor is it to be expected in a state so thinly peopled, and whose settlements for the most part lie contiguous to some navigable waters. In 1853 there were 54 miles of railway completed, one connecting St Mark's with Tallahassee, and the other Iola and St Joseph's.

There is no system of free schools in Florida, nor any college. According to the census report of 1850, there were 69 public schools, and 34 academies and other schools. Schools.

Of the 177 churches in Florida, 56 belonged to the Baptists, 10 to the Episcopalians, 1 to the Free Church, 87 to the Methodists, 16 to the Presbyterians, 5 to the Roman Catholics, and 2 to minor sects, having a total accommodation of 44,960 sittings. Value of church property, $165,400. (J. S. H.) Religion.

FLORIN is sometimes used to signify a coin, and sometimes a money of account. Florin, as a coin, is of different values, according to the different metals, and different countries where it is struck. See MONEY.

FLORINIANI, an obscure Gnostic sect in the early Christian church, who owed their origin to Florinus, a pupil of Polycarp, and a presbyter of Rome, excommunicated by the Bishop Eleutherius. They never numbered among their members any person remarkable either for intellect or influence, and the history of their doctrines is involved in as much obscurity as that of their origin and progress. It is only known for certain, from a passage in Eusebius (*Hist. Eccles.* lib. v., cap. 20), that they adopted the Gnostic heresy.

FLORIS, FRANZ, a distinguished Flemish painter, born at Antwerp in 1520. He began the study of art as a sculptor, but in his twentieth year laid aside the chisel and devoted himself to the more congenial pursuit of painting. A pilgrimage to Italy, and a careful study of the great masters of Italian art, so modified his taste and manner that on returning to his native city he adopted their style and attained such eminence in it as to earn the title of the Flemish Raphael. His best works are his "Twelve Labours of Hercules," and "The Last Judgment," now in the Museum at Brussels; and his "Adoration of the Shepherds," and "Fall of the Rebel Angels," at Antwerp. Floris died in 1570.

FLORUS, LUCIUS ANNÆUS, author of the *Epitome de Gestis Romanorum*, was a native of Spain, or, according to others, of Gaul, and lived under the Emperors Trajan and Hadrian. A good deal of difficulty and variety of opinion prevails as to the identity of this Florus. By some writers he is thought to be the Lucius Julius Florus who lived in the time of Augustus, and to whom Horace addressed two of his epistles; but this position is hardly tenable, as Florus in the introduction to his history talks of the Emperor Trajan as then reigning. By others he is identified with the Julius Florus or Floridus, who lived in the time of Hadrian, and wrote the *Pervigilium Veneris*, an imitation of Horace's *Secular Hymn*. This idea is equally gratuitous with the other. The *Epitome* of Florus gives a condensed view of Roman history from the foundation of the city to the closing of the temple of Janus by Augustus. The details of geography and chronology are not always to be implicitly trusted; but the general view of Roman history is striking and philosophic. The style is inflated and declamatory, and rather that of a panegyrist than of a critical historian. The *Epitome* is chiefly useful as a sort of substitute for the last books of Livy. The best editions of Florus are that of *Titze*, Prague, 1819; and that of *Duker*, Leipzic, 1832, which last is generally regarded as the standard edition.

Flotsam.

FLOTSAM, JETSAM, and LIGAN. In order to constitute a legal wreck the goods must come to land. If they continue at sea, the law distinguishes them by the barbarous

and uncouth appellations of *jetsam*, *flotsam*, and *ligan*. Jetsam is where goods are cast into the sea, and there sink and remain under water; flotsam is where they continue swimming on the surface of the waves; ligan is where they are sunk in the sea, but are tied to a cork or buoy, in order that they may be found again. Jetsam, flotsam, and ligan belong to the king, or his grantee, if no owner appears to claim them within a year. They are accounted so far distinct from legal wreck, that by the king's grant of wrecks, things jetsam, flotsam, and ligan will not pass.—(*Blackstone*, b. i., c. 8.)

FLOUR, St, a town of France, capital of a cognominal arrondissement in the department of Cantal, 33 miles E.N.E. of Aurillac. It stands on a basaltic plateau 300 feet high, at the foot of which flows the Dauzan. The town is ill-built, with narrow and irregular streets; and the houses being constructed of basalt give it a dull and sombre appearance. It is, however, the seat of a bishopric, and has tribunals of primary instance and commerce, a communal college, public library, agricultural society, museum, hospital, and a public fountain. Pop. (1851) 5254.

FLOWER, in botany, that part of a plant which is especially subservient to the production of seed. In its common acceptation the word is used for the flower-bud of a plant when the petals are expanded.

Preserving of Flowers, &c. The preserving of flowers in their natural beauty throughout the whole year has been attempted by gathering them when dry and not too much opened, and burying them in sand; but this, though it preserves their figure well, diminishes the liveliness of their colour.

The flowers of plants are by much the most difficult parts of them to preserve in any tolerable degree of perfection. Sir Robert Southwell has proposed a method of drying plants, by which these defects are said to be in a great measure remedied. For this purpose two strong plates of iron are prepared of the size of a large half sheet of paper, or larger; and in these there must be a hole made near each corner for receiving a screw to bring them closely together. Gather the plants with their flowers when they are quite perfect, in the middle of a dry day; and then place the plant and its flower on a sheet of paper, spreading out all the leaves and petals as nicely as possible. If the stalk be thick, it should be cut in two, so that it may lie flat: if woody, the bark alone should be retained. When all is thus prepared, lay several sheets of paper over the plant, and as many under it; then put the whole between the iron plates, and having screwed them close, put them into an oven after the bread is drawn, and let them lie there two hours. When the flowers are removed from the pressure of the plates, rub them lightly over with a camel's-hair pencil dipped in a mixture of equal parts of brandy and aquafortis; then dry them by gentle pressure between sheets of thick soft paper. When the plant is thus far prepared, take the bulk of a nutmeg of gum-dragon, put this into a pint of pure cold water, and let it stand twenty-four hours, in which time it will be wholly dissolved; and then with a fine hair-pencil dipped in this liquor, daub over the posterior sides of the leaves, and lay them carefully down on half a sheet of white paper, and press them down. When the gum water is fixed, let the pressure and paper be removed, and the operation is complete. The leaves in this case retain their verdure, and the flowers usually preserve their natural colours. Some care, however, must be taken that the heat of the oven be not too great. When the flowers are thick and bulky, they should be reduced by paring away a portion of the back; after which, if any of them are wanting, their places may be supplied with some of supernumerary ones dried at the same time; and if any of them are faded, it will be better to substitute others in their stead. The leaves may be also disposed and mended in the same manner.

But the most valuable method of preserving living plants excluded from the atmosphere is by means of the Wardian case, for an account of which see Botany, vol. v., p. 107.

FLUDD, Robert (called in Latin De Fluctibus), an English physician and Rosicrucian philosopher, was the son of Sir Thomas Fludd, treasurer of war to Queen Elizabeth in France and the Low Countries, and was born at Milgate, Kent, in the year 1574. Blending the incomprehensible reveries of the Cabbalists and Paracelsians, he formed a new physical system, replete with mystery and absurdity, and believed in two universal principles, the northern or condensing, and the southern or rarefying power. Innumerable genii, as he conceived, presided over these powers, and committed the charge of diseases to legions of spirits collected from the four winds of heaven. In his estimation, a harmony subsisted between the macrocosm and the microcosm, or the world of nature and the world of man. It is impossible to enumerate all his fancies and whims, which, however absurd and extravagant, being supported by mysterious gravity and the semblance of erudition, attracted the notice of the philosophers of that age. Even Kepler himself thought the preposterous jargon of Fludd worthy of refutation, and Gassendi with the same view wrote his *Examen Philosophiæ Fluddianæ*, 1629.

Fludd wrote two books against Mersenne, the first entitled *Sophiæ cum Moria certamen, in quo lapis Lydius, a falso structore Patre Marino Mersenno monacho reprobatus, celeberrima voluminis sui Babylonici in Genesim figmenta accurate examinat*, Francfort, 1629, folio; and the second, *Summum Bonorum quod est verum Magiæ, Cabalæ, Alchymiæ, Fratrum Roseæ Crucis Verorum, Subjectum*, etc. 1629, folio. His other works were, 1. *Utriusque Cosmi, majoris et minoris, Technica Historia*, Appenheim, 1617, in 2 vols. folio; 2. *Tractatus Apologeticus integritatem Soc. de Rosea Cruce defendens*, Leyden, 1617; 3. *Monochordon Mundi symphoniacum, seu Replicatio ad Apologiam Joannis Kepleri*, Francfort, 1620; 4. *Anatomiæ Theatrum triplici effigie designatum*, ibid. 1623; 5. *Philosophia Sacra et vere Christiana, seu Meteorologia Cosmica*, ibid. 1626; 6. *Medicina Catholica, seu mysticum artis medicandi sacrarium*, ibid. 1626; 7. *Integrum Morborum mysterium*, ibid. 1631; 8. *De Morborum Signis*, ibid. 1631; 9. *Clavis Philosophiæ et Alchymiæ Fluddianæ*, ibid. 1633; 10. *Philosophia Mosaica*, Goudæ, 1638; and, 11. *Pathologia Dæmoniaca*, ibid. 1640.

FLUSHING, a town of Holland. See Vlisslingen.

FLUID, an appellation given to all bodies the particles of which yield, without separation, to the slightest pressure. See Hydrodynamics, and Pneumatics.

FLUTE, a wind-instrument of great antiquity, the older varieties of which are described by Père Mersenne in his *Harmonie Universelle*, Paris, 1636. The *Flute-à-bec* (disused for more than a century) was of various dimensions. The largest was a bass-flute, with a compass from F in the bass-clef, below the first line, up to D below the first line of the treble clef. The next, a tenor-flute, extended from B flat on the second line of the bass clef up to G on the second line of the treble clef; and each of these large flutes was sounded through a bent tube, like the S of a bassoon. The alto-flute reached from F on the fourth line of the bass clef up to D on the fourth line of the treble clef. The treble-flute extended from F in the first space of the treble clef up to F two octaves above. These two had *beaks*, like the bill of a cock. But all these flutes gave way, early in the last century, to the German flute, which, however, was then very imperfect in its intonation, having only one finger-key. By the addition of various finger-keys, for semitones, the German flute has been much improved in the present century. Like the fife, it is blown by an oval side-hole. It consists of four separable tubes, and has a compass of nearly three octaves, from the lowest C in the treble clef upwards. Smaller flutes of this kind are called third, fourth, and octave flutes. The octave flute is the *piccolo*, used in modern orchestras and in military music. See Music. (G. F. G.)

FLUX, a general term for any substance employed to promote the fusion of metals or minerals, as alkalies, borax, tartar, &c.; and in the large way, limestone, and fluor-spar.

FLUXIONS.

INTRODUCTION.

The calculus of fluxions, the most important addition that ever was made to the fabric of abstract science, was invented in the latter part of the seventeenth century. Considered as a purely intellectual speculation, it far transcends any theory that had been previously known in pure mathematics; and it is not less estimable by reason of its applicability to physical knowledge. By its powers as an instrument of analysis, the science of geometry has been exceedingly enlarged; and the elegant speculations of the ancient geometers now go but a little way into the vast field of knowledge which has been laid open by the fluxional calculus, the sublime discoveries of Apollonius and Archimedes being merely easy deductions from more extended theories. It has, further, rendered most efficient aid in the investigation of the laws of nature, more especially in establishing the true theory of the motions of the heavenly bodies, which, without its assistance, could not have attained its present high position in the scale of human knowledge.

It may easily be supposed that the invention of the calculus was not at once fully revealed to the world. Its principles being inherent in the nature of geometrical magnitude, they would of course be gradually disclosed with the advance of mathematical science.

As long as the geometers of antiquity confined their speculations to the comparison of figures bounded by straight lines, there was no difficulty. The axioms and the mental process of conceiving the magnitudes compared to be placed one upon another, was sufficient to establish the equality of triangles in the cases when these could be brought entirely to coincide. The principle of superposition might have been carried further in the elements, so as to prove the equality of parallelograms, which are the complements of those about the diameter of a parallelogram; also of parallelograms having equal bases and altitudes; and the equality of the square on the hypotenuse of a right angled triangle to the squares on its sides. In fact, the doctrines of plane geometry were sufficient to prove that any two equal rectilineal figures admit always of being decomposed into spaces, such that, corresponding to every space in one of the figures, there may be found a space exactly equal and similar to it in the other figure; so that in this way any two equal rectilineal figures, however dissimilar, may yet, by division, be brought to coincide.

The principle of superposition, which was sufficient for the comparison of rectilineal plane figures, one with another, could not, however, be extended to the comparison of rectilineal with curvilineal, or of curvilineal with curvilineal figures. In treating of these, the ancients found it necessary to introduce new notions and modes of demonstration into geometry; and the difficulty which occurred in reasoning about curvilineal figures gave rise to the method of exhaustions, the most refined and important of their geometrical theories.

The fundamental principle of the method of exhaustions is this very simple proposition, that the difference of any two unequal quantities, by which the greater exceeds the less, may be added to itself so often, as to exceed any finite quantity of the same kind. On this the geometers of antiquity founded their propositions concerning curvilineal figures. By its aid they found that polygons may be inscribed in circles, which shall differ from them by less than any assignable space; and hence they might infer that the circles have to each other the same ratio as similar polygons inscribed in them, namely, the squares of their diameters. Although in this way they could assure themselves of the truth of the propositions, yet as this kind of proof was of a looser nature than that by which they established their more elementary doctrines, they fortified it against all cavil by their usual mode of synthetic demonstration, proving that the square of the diameter of one circle was to that of another as the first circle to a space that was neither less nor greater than the second, and therefore exactly equal to it. By a like process they proved that a cone is one third of a cylinder of the same base and altitude; and from the demonstrations which they gave of these propositions, it might be concluded in general, that when two variable quantities which have a constant ratio approach to two determined quantities, so as to differ at last from them by less than any assignable space, the same constant ratio is also the ratio of the determined quantities, which are the limits of the variable quantities.

Introduction.

The cautious way in which the ancients proceeded in finally establishing the truth of their propositions concerning the proportions of solids, could be of very little use in their original discovery. Indeed we may reasonably suppose, that in the first instance they arrived at a knowledge of their truth by a much shorter road, probably in a way not very different from that followed by the earlier geometers in modern times, who have extended their theories. But whatever path they followed, it led them to some truths of the highest importance at the time they were first known. After ages of fruitless labour in attempting to square the circle, the fine discoveries of Archimedes, that the parabola was two thirds of its circumscribing parallelogram, and the sphere two thirds of its circumscribing cylinder, and its surface four times that of one of its great circles, must have been received by his contemporaries with high satisfaction.

In the beginning of the seventeenth century, the writings of Archimedes greatly engaged the attention of the principal cultivators of mathematical science, who soon seized the spirit of his method, which was altogether distinct from the unwieldy machinery of the ancient mode of synthetic demonstration. He had only considered such solids as could be generated by the revolution of conic sections about an axis, and he had not even exhausted all the cases of these. The celebrated Kepler greatly extended this theory, in a treatise which he composed on the mensuration of round solids. These he conceived to be formed by the revolution of the conic sections about any ordinate, or a tangent to the curve at the vertex, or, in short, about any line whatever within or without the curve. In this way he described about ninety new solids, and proposed them as problems for the consideration of his contemporaries; but of these he resolved only a few of the most simple. In this work he first introduced the name and notion of infinity into the language of geometry. He considered the circle as composed of an infinite number of triangles, having their vertex at the centre, and forming the circumference by their bases. The cone he regarded as composed of an infinite number of pyramids, resting on the infinitely small triangles which formed its circular base, and having their vertices at its vertex; and he supposed a cylinder of the same base and altitude as the cone to be made up of prisms having the

same bases and altitudes as those which composed the cone.

The bold extension which Kepler thus gave to the cautious language of geometry drew the attention of his contemporaries, some of whom eagerly followed in his steps. Cavalieri, a friend and disciple of Galileo, embodied the new views in his geometry of indivisibles, the theory of which he possessed in 1629, although it was not published until 1635. In this work, lines were considered as made up of points, surfaces as composed of lines, and solids as formed of surfaces. Cavalieri was exceedingly careful to verify his method, comparing his results with those which had been established by the ancient geometrical mode of demonstration; and, assured by their agreement, he ventured boldly in his new career. His principles were attacked, but he defended them by showing that they might be translated into those of Archimedes, from which they only differed in brevity of expression; his surfaces and lines being in fact merely the thin solids and small inscribed and circumscribed triangles of the ancient geometer, and their number being supposed so great that the difference between them and the figure about which they were described was less than any assignable quantity.

The new views proposed by Kepler were taken up in France by Roberval, who had carefully studied the writings of Archimedes, and formed a theory by which he could resolve problems concerning curvilineal figures. Instead of supposing lines to be made up of points, and surfaces of lines, as had been assumed by Cavalieri, he regarded a line as composed of an infinite number of infinitely short lines, a surface as composed of an infinite number of infinitely narrow surfaces, and so on; an assumption which at bottom was the same as that of the Italian geometer, but capable of being wrought up into a theory differing less from the spirit of the ancient geometry. Roberval concealed his views, employing them secretly as the means of invention in geometry, and expecting in this way to get the start of his contemporaries in reputation as a geometer. In the meanwhile the work of Cavalieri appeared and frustrated his selfish expectations.

The facility which the introduction of the notion of infinitely small quantities gave in the extension of geometry, induced all the mathematicians of that day to employ it in their researches. In the doctrine of curve lines it was applied to the theory of tangents by Roberval, Descartes, and Fermat, with great success. So very near had this last-mentioned geometer approached to the fluxional or differential calculus, that Laplace says he ought to be reputed its true inventor. Laplace was no doubt a great authority; but the facts on which he formed his opinion have always been generally known, and no one before him has attempted to reverse the decision of the age in which the calculus was invented. The justice of the decision has been subjected to a scrutiny by men of the highest powers of mind, who, differing in many of their opinions, have yet agreed in ascribing the invention to others.

The problem of drawing tangents to curves is indeed closely connected with the calculus, and at the period when this was about to be revealed that problem was much agitated, and successfully resolved by Slusius, Wallis, Barrow, and others. The writings and discoveries of Descartes exerted a most beneficial influence on the new geometry, particularly by his happy application of algebra to geometry. Before his time geometrical problems had been resolved by algebra, and a rich mine of discovery thereby opened. But he was the first who thought of applying algebraic formulæ to express the nature of curve lines; an invention of vast importance to both branches of mathematical science.

Another most important benefit that resulted from the new views which Descartes brought forward, was the notion of *variable quantity*. The early analysts distinguished quantities chiefly from the circumstance of their being known or unknown; and the main object of inquiry with them was to discover the chain of reasoning by which they might pass from the given quantities to the determination of those required. The view which Descartes took of geometrical magnitude brought the *relations* of quantities forward as a principal subject of contemplation. A new subject of discussion was brought into mathematical science, namely, the changes which take place in quantities connected by an invariable relation, when one of them is supposed to change its value, and pass from one state of magnitude to another. The science of geometry owes its elegance and the variety of its doctrines to the combined effect of magnitude and position, as they influence the subjects under consideration; and, in addition to these, the doctrine of curve lines has introduced a new element, namely, the property of varying in magnitude, as an attribute of quantity. This property of indefinitude, in respect of greatness, although it may appear a trivial affection of quantity, has, however, led to the most important consequences; for from this, combined with other principles, have sprung the fluxional calculus and other mathematical theories, which, originating in the ordinary conceptions of the human mind, have engaged the attention of men endowed with the highest powers of intellect for more than a century past.

In the progress of time the notions of infinite quantity introduced by Kepler, Cavalieri, and others, into mathematics, became familiar to geometers, who perceived the immense value of the improvement, and saw that, by due care in its application, there was no risk of its leading into error. Dr Wallis, in the year 1655, gave an admirable specimen of this new analysis in his *Arithmetic of Infinites;* a work which contained the first traces of the algebraic analysis applied to the quadrature of curvilineal spaces. Pursuing the views of Cavalieri, he reduced the problem of finding the areas of curves to the summation of the powers of an arithmetical series, consisting of an infinite number of terms, or rather the ratio of the mean of all the terms to the last term. He also showed by the same principles, that certain curve lines might be *rectified*, or that straight lines might be found to which they were exactly equal; a remark that was shortly afterwards verified by William Neil, a young mathematician of that period, who, at the age of nineteen, showed that the length of the semicubical parabola might be found in finite terms. This was the first curve that was rectified, and the second was the cycloid, a discovery due to Sir Christopher Wren.

Thus the principles of the fluxional calculus were at this period coming gradually into view. Their importance was seen and understood, and in substance, although without an appropriate notation, they were employed in extending the dominion of geometry; it might therefore be supposed that in the course of time they would have been gradually formed into a system, just in the way the science of algebra advanced from the rude form it had when first introduced into Italy, to that degree of compactness and perfection which it acquired by the successive improvements of Vieta, Harriot, and Descartes. But, in the case of the fluxional calculus, a happy combination of circumstances anticipated the slow operation of time. Newton and Leibnitz, two men endowed with the highest powers of mind, appeared nearly at the same time in the field of discovery. The genius of each shone with resplendent lustre, even amidst the blaze of intellect which enlightened the latter period of the seventeenth century, and which has rendered it for ever memorable in the annals of hu-

man knowledge. They both turned their attention to this branch of mathematical science, and, as is now generally admitted, each, independently of the other, collected the undigested principles into a system, and, by a powerful effort, performed at once what the united labour of ordinary minds would have hardly accomplished in a century.

In ascribing to each of these great men the full honour due to the merit of the invention of the calculus, it is proper to add, that this is a question which at one time divided the opinions of the learned world, and gave rise to a controversy which was agitated with great keenness for almost a whole century. There never could be any doubt as to Newton being the inventor of the calculus of fluxions. He has been acknowledged by all to have been the inventor, and the first inventor; but the question strongly contested has been, whether Leibnitz, without knowing what had been done by Newton, invented his differential calculus by the force of his own mind, or borrowed it from the fluxional calculus, with which at bottom it is identical.

In the course of this controversy it was clearly established by the British mathematicians, who almost to a man ranged themselves on the side of their illustrious countryman, that, as far back as the year 1669, Newton, then in his twenty-sixth year, and a fellow of Trinity College, communicated to Dr Barrow a tract, entitled *De Analysi per Æquationes Numero Terminorum Infinitas.* In this manuscript the method of fluxions was first indicated; and rules deduced from it given for the quadrature of curves, and various other matters to which the calculus is applicable, were distinctly specified. From this tract, which was sent by Dr Barrow to Collins, the secretary of the Royal Society, it is established beyond all doubt that Newton was then in full possession of his method; and indeed it is certain from other evidence that he must have had it as far back as 1666. The important discoveries made by Newton were communicated without reserve by the secretaries of the Royal Society to mathematicians on the Continent, as well as to those in Britain. In this way it might be generally known that Newton possessed a most valuable instrument of research, by which he had been led to these results, although its nature was too obscurely indicated to give any assistance in divining its precise form.

Leibnitz appears to have been later than Newton in beginning his career of discovery in the mathematics. In the year 1672, being then in London, he communicated to some members of the Royal Society what he supposed to be discoveries relating to the differences of numbers. It was, however, shown to him that the same subject had been discussed long before, by Mouton, a French geometer. He then appears for the first time to have turned his attention to infinite series. Afterwards, on his return to Germany in 1674, he announced to Mr Oldenburgh, then secretary of the Royal Society of London, that he possessed very general analytical methods, by which he had found theorems of great importance relating to the quadrature of the circle, by means of series. In answer, the secretary informed him that Newton and James Gregory had also discovered methods which gave the quadrature of curves, and which extended to the circle.

In the year 1676 Newton addressed a letter to the secretary of the Royal Society, which was made known to Leibnitz. This was the first direct communication between these two great men. It contained the binomial theorem, which Newton had known in the year 1669, and a variety of other matters relating to infinite series and quadratures; but nothing directly relating to the method of fluxions. At this time Newton entertained no jealousy of Leibnitz, for he speaks of him in the letter with great respect. In a second letter Newton explained at his request the way in which he had found the binomial theorem, and he adverted also to his own calculus, explaining the purposes to which it could be applied, but concealing its nature under the form of an anagram of transposed letters, which was expressed thus, 6*accdae*13*eff*713*l*9*n*4*o* 49*rr*4*s*9*t*12*vx*. It is not easy to see what certain information Leibnitz could draw from this assemblage of characters; yet such was the effect of national prejudice in biassing the minds of the British mathematicians, that Raphson, in his *History of Fluxions*, a work dedicated to the Royal Society of London, expressly asserts that Leibnitz deciphered the anagram, and found it to be this sentence, *Data equatione fluentes quotcunque quantitates involvente invenire fluxiones, et vice versa.* "Having any given equation involving never so many flowing quantities, to find the fluxions, and *vice versa.*" We believe there was not the least ground for this assertion; and from such a specimen of want of candour, it is easy to infer that there was very little chance of Leibnitz getting justice done him by the English mathematicians.

In the month of June 1677 Leibnitz sent to Mr Oldenburgh, to be communicated to Newton, a letter containing the first essays of a method which extended to all that could be done by that of Newton. The death of Oldenburgh, which happened soon afterwards, put an end to the correspondence, and it was not until the year 1684 that Leibnitz made his discovery public, it being then inserted in the Leipsic Acts; so that whilst Newton's claim to the priority of the discovery must be admitted by all, it is not less certain that Leibnitz was the first to give the full benefit of the calculus to the world; for Newton's Method of Fluxions only became generally known in the year 1687, by the publication of his *Philosophiæ Naturalis Principia.*

It is certain that Leibnitz enjoyed unchallenged for fifteen years the honour of being the inventor of his calculus; even Newton himself rendered him that justice in the first edition of his immortal work. Subsequently, however, a foreign mathematician, Fatio de Duillier, piqued, it is said, by having been omitted in an enumeration of eminent geometers by Leibnitz, declared, in a treatise on the line of shortest descent, printed at London in 1699, that he was obliged by the undeniable evidence of things to acknowledge Newton not only as the first, but as by many years the first inventor of this calculus; from whom, whether Leibnitz, the second inventor, borrowed any thing or not, he would rather they who had seen Newton's letters and other manuscripts should judge than himself.

The insinuation contained in this passage of Fatio's book could not but be very offensive to Leibnitz, who inserted an animated reply in the Leipsic Acts of 1700, and complained to the Royal Society of London of the injustice done him; and here the affair rested for a time: but it was revived some years afterwards. When Newton's treatise on the quadrature of curves, and his enumeration of lines of the third order, was published, the Leipsic journalists gave an unfavourable review of the work. Amongst other things, after a brief exposition of the nature of fluxions, they added, that Newton uses and has always used fluxions for the differences of Leibnitz, just as Fabri had substituted in his synopsis of geometry motion instead of the indivisibles of Cavalieri. This most unjust accusation excited great indignation in the minds of the British mathematicians, one of whom, Keill, Savilian professor of astronomy at Oxford, in a paper inserted in the *Philosophical Transactions* of the year 1708, affirmed that Newton was the first inventor of the calculus, and that Leibnitz, in publishing it in the Leipsic Acts, had merely changed the name and the notation. Leibnitz, thus directly charg-

Introduction.

ed with having taken his calculus from that of Newton, addressed a letter to Mr, afterwards Sir Hans Sloane, the secretary of the Royal Society, in which he required that Keill should retract his accusation. Keill however refused to do this, and in answer addressed a letter to the secretary, in which he professed to show, not only that Newton had preceded Leibnitz in the invention, but that he had given so many indications of his calculus that its nature might easily be understood by any man of ordinary understanding. This letter was sent to Leibnitz, who addressed a second letter to the Royal Society, requiring that they should stop these reproaches of Keill, saying that he was too young a man to know what had passed between him and Newton.

The society, thus appealed to as a judge, appointed a committee to examine the old letters, papers, and documents which had passed between the mathematicians on the subject. The report of this committee does not appear altogether satisfactory. "We take the proper question to be," say the reporters, "not who invented this or that method, but who was the first inventor of the method; and we believe those who have reputed Leibnitz the first inventor, knew little or nothing of the correspondence between Mr Collins and Mr Oldenburg long before, nor of Mr Newton having that method about fifteen years before Mr Leibnitz began to publish his in the *Acta Eruditorum* of Leipsic; for which reason we reckon Mr Newton the first inventor, and are of opinion that Mr Keill, in asserting the same, has been nowise injurious to Mr Leibnitz." This declares nothing on the only point about which there could be any doubt, namely, whether Leibnitz had formed his calculus entirely by the power of his own genius, or had availed himself of a knowledge of Newton's invention. The judgment satisfied neither party. Keill wished to establish against Leibnitz the charge of plagiarism, but was disappointed; and Leibnitz found in the decision grounds of complaint against the Royal Society. In a communication to the Abbé Conti, a Venetian nobleman and a common friend of his and Newton, then in England, he accused the English nation of desiring to be considered as almost the only inventors. He said it did not appear, as had been well observed by Bernoulli, that Newton possessed before him the infinitesimal characteristic and algorithm, although it would have been easy to have found it if he had been so disposed, just as it would have been easy for Apollonius to have discovered the theory of curve lines of Descartes. He complained that his opponents had attacked his candour by forced and unfounded interpretations of his words. The question was the calculus of differences, and his opponents made it turn entirely upon series, where Newton had no difficulty in going before him. He maintained that he had found for himself a general method for series, and that he had no need of Newton's method of extractions. There were other grounds of complaint, such as, that only extracts from letters had been given in the *Commercium Epistolicum*, whereas the entire letters should have been published. Throughout the whole, which is a postscript to a letter, he manifests much chagrin; and he concludes with proposing this problem, intended, he says, to feel the pulse of the English analysts: To find a line which shall cut perpendicularly all curves of a determinate species, and of the same kind; for example, all hyperbolas, which shall have the same vertex and centre. This he desires the abbé to propose as from himself, or a friend.

In the abbé's reply to this letter he informed Leibnitz that he had delayed writing until he could at the same time send the answer which Newton had given to his postscript. He tells him that he had read the *Commercium Epistolicum*, and the originals of the letters which it contained, and, on the whole, he inferred that, setting aside matters foreign to the dispute, the only question at issue was, whether Newton had found the Calculus of Infinitesimals, or Fluxions, before, or after him? The abbé says, you published it first, it is true; but you admit that Newton allowed much to transpire in the letters which he wrote to Oldenburgh and others. This has been proved at length in the *Commercium* and its extract; what is your answer? This is what the public requires, to form a correct opinion on the matter. The abbé further informs Leibnitz that his friends believe he ought to give an answer, if not to Keill, at least to Newton himself, who, in the letter which the abbé had received from him to be communicated to Leibnitz, had challenged him in express terms. In a spirit of friendship and good sense, he further adds, that he wishes to see a good understanding between them, that the public will profit but little by their disputes, and that the additions to knowledge which they prevent are a pure loss to posterity. He moreover tells him that the king, George I., had desired to be informed of all that had passed between Newton and him. From this we may judge what an interest was excited in the public mind by a dispute which, even at this day, few could perfectly understand. The answer which Leibnitz gave to the abbé's friendly advice was, that he had put his letters, and Newton's, with his own answers to them, into the hands of Mr Remond at Paris, with a view to have a neutral and impartial opinion as to the matters in dispute. The whole were then to be submitted to the Abbé Varignon and other members of the Royal Academy of Sciences, and afterwards sent to England. In his answers he disavowed the sense which the English mathematicians had extracted from the assertion of the Leipsic journalists, namely, that Newton employed and always had employed fluxions for the differentials of Leibnitz, which they understood to mean that Newton had availed himself of Leibnitz's method, only substituting fluxions for differentials. It was from this passage that the English had declared Leibnitz to be the aggressor, in having abetted an attack of Newton; but Leibnitz declared the English interpretation to be full of malignity towards him, and that the sentence in the *Leipsic Acts* (*Pro differentiis Leibnitianis D. Newtonus adhibet semperque adhibuit fluxiones*), meant that Newton had employed fluxions after having seen his differences, and also before he had seen them.

We believe enough has been detailed to show that, besides a desire to arrive at truth, there was infused into this controversy the jealousy of two rivals for the glory of a great discovery; and, in addition, the spirit of partizanship of their respective admirers, and that natural feeling which induces men of different countries to exalt their own nation, although sometimes at the expense of their neighbours. It is not wonderful, then, that at the time this controversy was at its height, men were greatly divided in their opinions.

It is now impossible to obtain absolute certainty as to the question, whether Leibnitz derived any aid from the discoveries previously made by Newton, which, to a certain extent, were made known to the scientific world. It may therefore be some satisfaction, in the want of perfect evidence, to have the judgment of Montucla, the historian of the mathematics, on this subject. "In regard to the principle of fluxions," says he, "there are only three places of the *Commercium Epistolicum* which treat of it with sufficient clearness to prove that Newton had found it before Leibnitz, but I believe too obscurely to take from him the merit of the discovery. One of these is a letter from Newton to Oldenburgh, who had remarked to him that Slusius and Gregory had found a very

Introduction.

simple method of tangents. Newton answered that he conjectured what it was, and he gave an example, which is in effect the same thing as these two geometers had found. He added that it was but a particular case, or rather a corollary to a method much more general, by which tangents to all sorts of curves, whether geometrical or mechanical, might be found without laborious calculation. He repeated the same thing, without explaining himself further, in his second letter, which has been already mentioned, and he concealed the principle under transposed letters. The only writing in which Newton had allowed any thing of his method to transpire is his *Analysis per Equationes numero Terminorum infinitas.* He there briefly and obscurely reveals his principle of fluxions. It cannot be denied that the principle and method were there indicated; but it is not certain that Leibnitz had ever seen the passage. His adversaries have never said that it had been communicated to him by letter; they have merely thrown out a suspicion that Collins might have communicated it to him in his second journey to London. Indeed the suspicion is not altogether void of probability, inasmuch as Leibnitz admitted that in his interview with the secretary he had seen a part of his epistolary correspondence. I believe, however, that it would be rash to pronounce upon this. There might have been grounds for suspicion if Leibnitz had merely given a few essays of his new calculus; but when we consider the improvements he made, as appears by the number of pieces he contributed to the *Leipsic Acts,* it seems probable that he owed his calculus to his own genius, and his efforts to divine the nature of a method by which Newton had made so many fine discoveries. This is the more probable, as from the method of tangents of Barrow to the differential calculus, the step is not too great to have been made by a power of mind of which Leibnitz had given so many proofs."

If it had been true, as the British mathematicians alleged, that Leibnitz had taken his calculus from that of Newton, it would have been a very remarkable circumstance that such a long period should have elapsed between his first putting forth his pretensions to the honour of the invention, and the denial of Newton and his friends. This is a thing uncommon in the history of contested claims to discovery, when both the claimants are alive and all the facts known. It is also remarkable that Newton, while in the prime of life, did not of his own accord bring forward a charge of plagiarism against his contemporary. On the contrary, in the first edition of his *Principia,* which appeared in 1687, he expressly admitted Leibnitz's claim; and this admission is found even in the edition of the *Principia* published in 1713. It is now well known, that before the period of the controversy between Newton and Leibnitz, the mind of the former had at one time been in a state which rendered him unfit to draw correct conclusions from the ordinary incidents of life; witness his letters to Mr Pepys and Mr Locke in September 1693 (Brewster's *Life of Newton*). At this time he seems to have laboured under great bodily indisposition, from which he afterwards in appearance recovered; indeed it may be doubted whether his temper was so equal and mild in the latter period of his life as has been represented by his biographers. A collection of letters which passed between Flamsteed the astronomer and Abraham Sharp the celebrated calculator, which have lately come into the possession of the Astronomical Society of London, prove that Newton, in conjunction with Halley, opposed Flamsteed in the publication of his *Historia Cœlestis,* a work of the highest merit, and the result of the labour of his life, with a pertinacity of purpose which is by no means an amiable trait in his character. It is certain that Newton entertained towards Leibnitz a very different feeling at one period of his life, from that which he in the end evinced. In the edition of the *Principia* 1713, and those which preceded it, he says, " Ten years ago, in a correspondence with Mr Leibnitz, I informed him that I had a method of determining maxima and minima, of drawing tangents, and resolving similar problems, which applied alike to rational and irrational terms, but concealed it under transposed letters. He answered that he had found a like method, which he communicated, and which differed from mine only in the terms and the signs, and in the way of conceiving quantities to be generated." This concession was liberal, and worthy of Newton. However, in the edition of 1726, he retracted this act of justice, having struck out the passage, as Montucla assures us, with his own hand. The historian of the mathematics, however, finds an excuse for this harshness in the treatment which Newton had received from Leibnitz's friends.

The circumstance of the calculus having had two distinct origins, had the inconvenient effect of giving it two different forms and names. Newton at different times used different notations before he finally adopted that which has been followed by the English mathematicians. Leibnitz and his followers employed one somewhat different; and each sect pertinaciously adhered to the example set by its leader. There was a still greater difference in the view which each party took of quantity, and the way in which it may be generated. Newton conceived geometrical magnitudes to be generated by continued motion, a line by a point in motion, a surface by a moving line, a solid by a moving surface, an angle by a line turning about a point, and so on. It is evident, that by assuming geometrical quantities as the representatives of time, force, and whatever can be expressed by number, these can be conceived to increase or decrease according to the same laws as their geometrical representatives. His calculus therefore consisted of two parts:

1*st,* Supposing two quantities to have a given relation to each other (for example, the one to be always equal to the square of the other), and the rate of increase of one of them at any instant of time to be known; to find the rate of increase of the other at the same instant. These rates of increase were called the *fluxions* of the quantities; and the rules for their determination constituted the *direct method of fluxions.*

2*d,* The second part was the reverse problem, in which the relation between the rates of increase of two quantities which depended the one on the other, being given, it was required to discover the relation of the quantities. This was the inverse method.

Leibnitz at first supposed quantity to increase by the addition of some indefinite portion of a quantity of the same kind, and his *differentials* were quantities proportional to the instantaneous changes in the greatness of the quantities thus generated. He afterwards found it shorter to introduce directly these instantaneous changes into his calculus under the name of infinitely little differences (*infiniment petites*). These however he did not regard as absolute *zeros,* but only as not comparable to finite magnitudes. His calculus had, like Newton's, two parts, the *differential calculus,* which gave rules for deducing the relation of the differentials of quantities from that of the quantities themselves, and the *integral calculus,* which resolved the reverse problem, or discovered the relation of the quantities when the relation of their differentials was known. This corresponded to the inverse method of fluxions, as the differential calculus corresponded to the direct method.

There is this distinction, then, between the two methods:

Introduction.

Newton's fluxions are any finite quantities which have to each other the ratio of the velocities, or degree of quickness with which the quantities are generated. The differentials of Leibnitz are infinitely small quantities, a creation of the mind more removed from ordinary apprehension than the finite representatives of fluxions. This distinction has often been urged in favour of the superiority of Newton's calculus. On the other hand, Newton has introduced time into his calculus. Now this is an element foreign to geometry, and belonging to mechanics, a quite distinct branch of science. The metaphysical distinctions between the two forms of the calculus have had but little influence on its progress. Whichever of the two forms is chosen, the rules are the same; and so also are the difficulties to be overcome.

Some time elapsed before the newly invented calculus was actively employed. At length Leibnitz, to rouse the attention of geometers, proposed in 1687 this problem: To determine the curve along which a heavy body must descend, so as to approach by equal distances in equal times to a horizontal plane. Huygens was the first to resolve the problem. He showed what was the nature of the curve; but he did not give his demonstration. James Bernoulli also resolved the problem by the differential calculus, and published his analysis in the *Leipsic Acts*. His younger brother John united himself in a close friendship with Leibnitz, and continued throughout life his coadjutor and staunch defender. He made the calculus known in France, where he resided for a time, and gave lessons to the Marquis de l'Hôpital. Part of these form the *Analyse des infiniment Petits*, a work which bears the name of the marquis, with but a slight acknowledgment in the preface of the share which his preceptor had in its composition. Indeed it was almost entirely his; and of this injury Bernoulli complained justly, but privately, in his correspondence with Leibnitz. The remaining lessons, which teach the integral calculus, are given in the collection of Bernoulli's works, published in 1742. The whole form an excellent exposition of the principles of the calculus, and contain some of its finest applications.

The continental mathematicians who were remarkable for their skill in the differential calculus were at first few in number. They might be nearly all included in the names of Leibnitz himself, James and John Bernoulli, De l'Hôpital, and Varignon. They were, however, remarkably active, particularly the Bernoullis, whose writings have contributed powerfully to its advancement.

The inventor of the fluxional calculus seems to have taken but little interest in its extension. His treatise on quadratures did not appear till 1706; and his work on fluxions was not published in his life time, but appeared in 1736, nine years after his death. He had however fully availed himself of its power in the composition of his *Principia*, without revealing to the full extent the nature of the instrument with which he wrought, but establishing the truth of his propositions by synthetic demonstration, after the manner of the ancient geometers. Probably this was done in deference to the taste of that time; for a contemporary writer, Hermann, in following his example in the composition of his *Phoronomia*, assigned to Leibnitz as a reason, that the geometrical method was likely to be better understood than the analytical in Italy. This way of proceeding is now, however, disused by the best writers, and replaced by the more legitimate and undisguised use of the calculus.

The extensive views which the new calculus opened up, afforded the means of resolving problems which had baffled the skill of the earlier mathematicians, and suggested many new ones, which without its aid would have been quite intractable. The cycloid and the catenary, curves which had eluded the penetrating mind of Galileo, were more fully comprehended; many new ones were suggested, and the cultivators of the calculus challenged each other to an investigation of their properties. There is an elegant class of problems which relate to the greatest and least values of quantities. Some of these, called problems of *maxima* and *minima*, can be resolved by the ordinary geometry and algebra; but there is a class which lies beyond the dominion of these, and to it belongs the solid of least resistance, the curve of swiftest descent, and, in general, the problems called *isoperimetrical*, one of the simplest of which is to find the nature of the line which, being given in length, shall comprehend the greatest possible space. These formed the subject of a warm but honourable contest between the two Bernoullis, brothers; and their investigation laid the foundations of that branch of the calculus, the highest, which has been formed into a theory by the labours of Euler and Lagrange, under the name of the *Calculus of Variations.*

Among the early cultivators of the calculus in Britain we may reckon Cotes, the friend of Newton, who died at the early age of thirty-four (his *Harmonia Mensurarum*, and other writings, indicate a genius of the highest order), De Moivre, Taylor, Craig, David Gregory, and Stirling. It must, however, be confessed, that the continental school in the course of time advanced before that of Britain, as well in the number of its disciples, as in their high mathematical genius and the importance of their discoveries. John Bernoulli had two sons, Nicolas and Daniel, who rivalled their father's skill in the applications of the calculus; and these had as condisciples Hermann and Euler. This last mathematician has carried the subject to a point of perfection far beyond what it had attained in the hands of those that had gone before him.

Amongst the means by which the improvement of the calculus has been promoted, we may reckon the problems which passed between the British and continental mathematicians as challenges to each other, in answering which Newton himself condescended sometimes to enter the lists. The doctrine of infinite series, a branch of the mathematics of English origin, gives powerful aid to the calculus in its greatest difficulties; but, legitimately, its assistance ought not to be called in if the problem admit of being resolved in finite terms. The English sometimes failed in the observance of this most proper condition of a good solution, and thus gave rise to reproaches from their opponents, which in at least one instance were not unjustly incurred by Newton himself. In the course of this warfare, Keill, the champion of the English, proposed as a challenge to John Bernoulli, to determine the nature of the curve which a projectile describes in a medium resisting as the square of the velocity. Bernoulli soon resolved the problem, not only in the case proposed, but also when the resistance was as any power whatever of the velocity. He then proposed to put his solution into the hands of some confidential person in London, provided that Keill would deliver his solution to the same person. Keill, however, had upon trial not been able to resolve the problem, and therefore preserved a profound silence, and made himself, by his boasting and failure, quite ridiculous. The triumph of Bernoulli was complete, and he did not miss the opportunity of bestowing severe castigation on his humbled adversary, recollecting, we may suppose, the treatment which his deceased and lamented friend Leibnitz had received from him and his friends.

As another proof of the spirit and rivalry of the supporters of the two analytical theories, we may mention that Brooke Taylor proposed a problem in the integral calculus to all geometers not English, and sent it to Mr Montmort to be communicated to the foreign geometers.

Notwithstanding the general terms of the challenge, it was well understood to be particularly aimed at John Bernoulli, who in return offered to wager fifty Louis that he would resolve the problem, and to stake fifty more that he would propose a problem which he himself could resolve, but which Taylor could not. The English mathematician did not think it prudent to accept the offered condition. Indeed it was a complaint against the English geometers, that although they made no scruple of trying to puzzle foreigners with difficulties, they rarely responded to the counter challenges proposed to themselves.

Perhaps there never was a considerable invention or discovery which had not to encounter opposition; sometimes from the slowness with which the human mind yields to the force of truth when opposed to long-received opinions, and sometimes from less excusable causes, such as mistaken or interested views, or mere jealousy excited by the fame of the inventor. The new calculus had in the very outset its opponents, such as the Abbé de Catelan, a zealous Cartesian, who declared that it would be better to extend the principles of the Cartesian geometry than to seek for new methods; and this was said in the preface of a book composed on the principles, somewhat disguised, of the very calculus of which he was an opponent. It had another adversary in Nieuwentiit, a man who had written some tolerable works on morality and religion, but who had but small pretensions to be regarded as a geometer. Catelan was satisfactorily answered by De l'Hôpital, as was Nieuwentiit by Leibnitz, and afterwards by Bernoulli and Hermann, who proved that this adversary of the calculus really did not know what he opposed.

The calculus had a more formidable enemy in M. Rolle, a skilful algebraist and indefatigable calculator, but a man full of confidence in his own notions, rash in forming his opinions, and jealous of the inventions of others. He attacked the certainty of its principles, and he attempted to show that its conclusions were at variance with those obtained by methods previously known, which were acknowledged to be correct. His attack was repelled by Varignon, who completely obviated the objections to the truth of the principles, and further showed that the supposed discrepancy between its conclusions and those obtained by other methods, were mistakes he had committed from haste and inadvertence. These disputes occupied the French Academy a considerable part of the year 1701. The members were chiefly geometers considerably advanced in years, who had been long accustomed to other methods, and were therefore not much disposed to receive new doctrines. Some took no part in the dispute, yet were not sorry to see a storm raised against a theory for which they had no great liking, and took no means to allay it; others, more under the influence of their passions and prejudices, yielded to these, and declared open war against it. In this state of things the best course was supposed to be that of hearing all which could be said for and against the calculus. The academy was long involved in the dispute. Rolle brought forward objection upon objection; and although Varignon continually obviated them, yet the former always claimed the victory. In the end the dispute degenerated into a real quarrel, and commissioners were appointed to decide on it. These were Père Gouye, MM. Cassini and de la Hire, who, however, pronounced no judgment; but the public opinion, or at least the opinion of geometers, was in favour of Varignon. The first controversy thus ended, or at least was suspended, for want of a decision from the commission; but Rolle, the champion of the opponent of the calculus, soon renewed hostilities. Its defence was next taken up by M. Saurin. The ground of attack was the indefinite form which the calculus gives for the subtangent of a curve at the point where two branches intersect each other, and which in this case is expressed by the fraction $\frac{0}{0}$.

Saurin's answer was satisfactory; but Rolle, intrenched in masses of calculation, obstinately maintained the combat. The academy was again appealed to. The Abbé Bignon, who conducted its affairs, undertook to decide the controversy, with the assistance of MM. Gallois and De la Hire, two judges by no means favourable to Saurin. They gave no absolute judgment; but recommended to Rolle to conform more strictly to the rules of the academy, and to Saurin to forgive the proceedings of his adversary. Rolle suffered in the estimation of competent judges; he, however, afterwards did justice to the calculus, by acknowledging that he had done wrong in opposing it, and admitting that he had been urged forward by the instigation of malevolent persons, one of whom was the Abbé Gallois; and his demise in 1707 accordingly put an end to the controversy.

In England the Newtonian calculus had to sustain an attack on its principles from a writer of first-rate talents, Berkeley, bishop of Cloyne. The circumstances which led to it are curious. Mr Addison had given the bishop an account of the behaviour of their common friend, Dr Garth, in his last illness, which was highly unpleasing to these two advocates of revealed religion; for when Addison began to discourse with Garth on a future state, "Surely," said the latter, "I have no reason to believe these trifles, when my friend Dr Halley, who has dealt so much in demonstration, has assured me that the doctrines of Christianity are incomprehensible, and religion itself an imposture." The bishop therefore took up arms against Halley, and in the year 1734 addressed to him, as an infidel, a discourse called The Analyst, the object of which was to prove that mathematicians acted inconsistently in objecting to mysteries in faith, seeing that they did not hesitate to admit much greater mysteries, and even falsehoods, in their own science; and he chose the principles of the doctrine of Fluxions, as laid down by Newton and adopted by his followers, to prove the truth of his proposition. It may be supposed that so able a writer would not fail to make an impression on the public mind. But the mathematicians were not slow in coming forward in defence of the doctrines of their chief. In the same year came out a tract with this title: "Geometry No Friend to Infidelity, or a Defence of Sir I. Newton and the British Mathematicians, by Philalethes Cantabrigiensis," supposed to be Dr Jurin. As usual the attack was renewed, and again repelled by the same hand. Other defences of Newton appeared, one of the best of which was from the pen of Benjamin Robins; it was entitled A Discourse concerning the Nature and Certainty of Sir Isaac Newton's Method of Fluxions, and of Prime and Ultimate Ratios. But the most important result of this controversy was A Treatise on Fluxions from the pen of Colin Maclaurin, professor of mathematics in the university of Edinburgh, printed in 1742. This defence of the principles of Newton's views, expressly intended to obviate all objections, is quite satisfactory. The treatise is indeed considerably prolix; but this was a consequence of the circumstances in which it was composed. It however contains a great deal more than a mere theory of fluxions. We have in it some of the finest applications of analysis to the principal problems which had been agitated amongst geometers from the invention of the calculus to the time in which the work appeared.

By the middle of the century the calculus proceeded with a rapid march of improvement. Euler in 1744 greatly enriched it by his solution of the Isoperimetric Problem (*Solutio problematis isoperimetrici latissimo sensu accepti*), a theory which he afterwards wrought up into the Calculus

Introduction.

of Variations, and which has been still further improved by Lagrange. Brooke Taylor, by his *Methodus Incrementorum*, had extended the foundations, and even proceeded a great way in the structure, of a kindred calculus, that of finite differences. Stirling had followed in the same path in his *Methodus Differentialis;* and Euler had opened a new field for discovery in the calculus of partial differences, in which D'Alembert followed his steps, and carried the subject further. The same period abounded in good writers. In this country Demoivre, Simpson, Landen, and Waring, stand among the foremost in the list for the originality of their views; on the continent Ricatti, Clairaut, Fontaine, and others, followed in the train of Euler and the Bernoullis.

It is a curious fact in the history of mathematics, that there are instances of ladies who have applied their talents to its study and improvement with much success. Hypatia, the daughter of the ancient geometer Theon, is one notable instance. Unfortunately we have no vestiges of her writings by which we might form an estimate of her proficiency in a science which at first sight seems not to have many attractions for the female mind. We have another instance in an Italian lady, Maria Gaetana Agnesi, who was actually professor of mathematics in the University of Bologna in the year 1748; and how well she was qualified for the office appears from her Analytical Institutions, a work of great excellence on algebra, the theory of curve lines, and the differential calculus, composed for the instruction of the youth of Italy. This work is so excellent, that Bossut, a French mathematician of great eminence, translated the part on the differential calculus into French, and incorporated it with his Course of Mathematics, as the best treatise he could find on the subject. There is also an English translation by the Rev. John Colson, Lucasian professor of mathematics in the university of Cambridge. Her countryman Frisi, a most competent judge, mentions her in enumerating the mathematicians of Italy, and bestows great praise on her work, calling it *opus nitidissimum, ingeniosissimum, et maximum certe opus quod hactenus ex feminæ alicujus calamo prodierit.* At the present time we have another admirable instance of a lady who has surmounted the difficulties of the calculus. Mrs Somerville, in her work entitled *Mechanism of the Heavens*, London, 1831, has enriched English literature with a treatise on physical astronomy, in which the different branches of the calculus are combined with the most refined theories of mechanics. Her book does her infinite credit, and indeed is highly honourable to the whole female sex.

Geometers have differed in opinion as to the best way of working up the principles of the calculus into a system. Newton, as has already been stated, employed the theory of motion as the means of connecting its doctrines with the principles of the ordinary algebraic analysis. Leibnitz, again, with the same view, conceived quantity as passing from one degree of magnitude to another by the continual accretion of infinitely small parts. The mind finds no great difficulty in distinctly apprehending the subject in its simplest state either way. Objections have, however, been taken to both, and attempts made to substitute a better. Euler considered the infinitely small quantities of Leibnitz as absolute zeros, that have to each other ratios derived from those of the vanishing quantities which they replace. D'Alembert proposed to make the basis of the calculus the consideration of the ratios of the limits of the quantities. An English mathematician, Landen, has substituted for the Newtonian method of fluxions another purely analytical. His views are contained in a work entitled The Residual Analysis, a new branch of the Algebraic Art, by John Landen, 1764. Lastly, Lagrange, in the Memoirs of the Berlin Academy for 1772, proposed to make the calculus altogether independent of the consideration of infinity, and to rest on principles purely analytical, thus connecting it with the doctrines of the ordinary algebra. He has since realised and extended his views in his *Théorie des Fonctions Analytiques*, also in his *Leçons sur les Calcul des Fonctions;* works which, from their excellence and the celebrity of their author, have formed a new era in the history of the calculus.

The twofold origin of the calculus, besides placing its principles on different foundations, gave it also two different forms of notation; and in this state it continued during the whole of the eighteenth century, to the great inconvenience of mathematical students, and, we may add, to the hindrance of the progress of science. A change, however, has taken place within the last twenty years; during that period some British geometers, imbued with the mathematics of the continent, adopted also its notation in preference to that of the followers of Newton, and employed it publicly in their researches. This spirit of innovation in time took possession of the minds of the junior members of the university of Cambridge, and now we may say that it has completely supplanted the native notation. We have retained the name of Fluxions, because, from the changes which have taken place in the way of treating the subject since the days of Leibnitz and Newton, it seems to be as proper as the term differential. It is otherwise with the notation. This is consecrated by its having been employed in the writings of Euler, D'Alembert, Lagrange, and other great masters in mathematical science; and besides, it has advantages over the other in point of symmetry and compactness, and the established reputation of a whole century of useful service. It is true, the late illustrious Lagrange laid it aside in his attempt above mentioned to new-model the calculus; but subsequent writers, in extracting what was excellent from his works, have in general invested his views with the ordinary notation of the continent. In the following treatise we shall conform to this beneficial alteration.

Writers on the Infinitesimal Calculus, before the Invention of the Method of Fluxions.

Kepler, Nova Stereometria Doliorum Vinariorum.............. 1615
Cavalieri, Geometria Indivisibilium.............................. 1635
——— Exercitationes Geometricæ Sex.............. 1647
Roberval, Traité des Indivisibles. Mém. de l'Acad. des Sciences 1666

De Morgan's Differential and Intégral Calculus ... 1842
Leçons de Calcul Différentiel et de Calcul Intégral, par M. l'Abbe Moigno, 2 vols ... 1840–4
Hymer's Intégral Calculus ... 1844
Exposé Elémentaire de la Theorie des Intégrals Définies par A. Meyer 1851, in the Memoires of the Royal Society of Science at Liège; and many valuable papers on the subject in the Journal de L'Ecole Royale Polytechnique, and in the Journal de Mathématiques Pures et Appliquées par Joseph Lionville.
Hall's Differential and Integral Calculus, fifth edition ... 1852
Todhunter's Differential and Integral Calculus ... 1852
Price's Infinitesimal Calculus, in 2 vols ... 1854
The last two are the most perfect treatises on the subject in the English language, and Price's abounds in lucid and elegant illustrations and applications of the subject.
Carmichael's Treatise on the Calculus of Operations, designed to facilitate the processes of the Differential and Integral Calculus, and the Calculus of Finite Differences; London 1855
Besides the above, many valuable papers have appeared on the subject in the Mathematician, and in the Cambridge and Dublin Mathematical Journals.
Levy's Differential and Integral Calculus in the Encyclopædia Metropolitana.

The preceding catalogue contains the names of the principal improvers and cultivators of the calculus, from its first invention to the present time (1855). However, it does not contain all their writings; to have enumerated these would have extended the catalogue to too great a length. Almost all the improvements of the calculus were first given in the form of academical memoirs, from which they have been drawn, and incorporated into the systems that have from time to time been published. The great repertories in which it is contained are the writings of Newton, Cotes, Demoivre, the Bernouillis, Maclaurin, Simpson, Euler, D'Alembert, Lagrange, Legendre, La Place, Monge, Poisson, Gauss, Ampère, Ivory, &c. From these have been constructed the treatises of De l'Hôpital, Bougainville, Le Seur and Jacquier, Cousin, and others, which were the most complete at the different periods when they appeared. At this time the most extensive treatise is the second edition of Lacroix, which came out between 1810 and 1819. In the present century there have been published in France treatises by Garnier, Du Bourguet, Bouchariat, Cauchy, and others which we have not seen. In Britain, we have had treatises by Woodhouse, Dealtry, Lardner, Jephson, Young, Thomson, and others. The university of Cambridge, long infertile, now teems with treatises on the subject. There are, besides, treatises on the calculus in courses of mathematics, such as the Elementi d'Algebra of Paoli, the Cours des Mathematiques of Bezout, a like work by Francœur, and a Course of Mathematics for the Naval and Military Academy by Dr Rutherford and others. There have also been works constructed for the benefit of students, which may be used with any treatise on the subject; such as the excellent collection of examples by Pea-

cock, Herschel, and Babbage, which was intended as an accompaniment to an English translation of an abridgment of Lacroix's treatise; and the integral tables of Hirsch, which have been translated from the original German into English. And since then Hind's Exercises on the Differential Calculus, and Gregory's Exercises in the Differential and Integral Calculus.

There is a branch of the calculus of great interest, which of late has engaged, and will probably long engage, the attention of mathematicians; we mean the subject of *Elliptic Transcendents*. This theory originated in the discovery of a very remarkable property of the ellipse and hyperbola by Fagnani, an Italian mathematician, who first showed that arcs of these curves can be assigned, of which the difference is expressible in finite algebraic terms. Legendre, who gave this name to functions represented by the integrals of this form, discovered several of their very remarkable properties, and deduced from them the means of calculating their approximate values. For all the interesting but lengthy and minute details of these important investigations, we must refer those who feel desirous of investigating them thoroughly, to the following list of treatises on the subject. The student, however, should be aware that the term fluxion is very seldom used by the best scientific scholars of the present time. The reader of such works should also be aware that not only is the notation of Newton different from that of Leibnitz, but that which the latter calls *difference* the former calls *fluxion*, because he supposes that the co-ordinates, and in general the quantities augmented indefinitely and gradually were produced by a flowing or fluxion of infinitely small parts.

PART I.

DIRECT METHOD OF FLUXIONS, OR DIFFERENTIAL CALCULUS.

1. In the application of algebra to the theory of curve lines, some of the quantities under consideration are conceived as having always the same magnitude as the parameter of a parabola, and the axes of an ellipse or hyperbola; others again are indefinite in respect of magnitude, and may have any number of particular values; such are the co-ordinates at any point in a curve. This difference in the nature of the quantities has equally place in various theories of the pure and mixed mathematics, and it naturally suggests the division of all quantities into two kinds; namely, such as are constant, and such as are variable.

A constant quantity is that which is supposed to have always the same value. A variable quantity, again, is that which may change its value by increasing or decreasing, so that in passing from one degree of magnitude to another it will have had in succession every possible intermediate magnitude.

Thus, in a circle, the radius is a constant quantity, and any arc of the circle, also its cosine, sine, tangent, secant, &c. are variable quantities. In the ellipse, the axes or semiaxes are considered as constant; and the co-ordinates to any point in the curve, and in general any lines or spaces or angles which in the same ellipse admit of different values, are variable. So again in the parabola, the parameter is constant, and the co-ordinates to any point in the curve, also any arc of the curve, and the space contained by that arc and the co-ordinates, are to be regarded as variable.

In what follows, we shall in general call constant quantities simply *constants*, and variable quantities *variables*.

It is usual to denote constants by the letters a, b, c, &c. towards the beginning of the alphabet, and variables by the letters x, y, z, &c. towards the end.

2. One quantity is said to be a *function* of another when they are so related that the latter being supposed to change its value, the former also changes its value. Thus, in geometry, the radius of a circle being constant, the cosine, the sine, the tangent, the secant, &c. are functions of the arc. On the other hand, the arc may be considered as a function of any one of these quantities. In mechanics, the force by which a body is urged forward, the space it has passed over, and its velocity at every instant, may all be regarded as functions the time.

In this algebraic expression,

$$y = \frac{a + x}{a - x},$$

in which a is a constant and x a variable, the quantity y is regarded as a function of x, which is called the *independent* variable. Here y is expressed by x; but by resolving the equation, x may be expressed by y thus:

$$x = \frac{a(y-1)}{y+1};$$

the quantity x is now a function of y. In either case, the constants a and 1 are not considered. In these examples,

$$u = a + bx + cx^2,$$
$$u = \sqrt{(a^2 + bx + x^2)},$$
$$u = \frac{a + \sqrt{bx}}{c + x^2},$$

u is a function of x.

A quantity may be a function of several independent variable quantities. Thus, in the expression

$$u = ax^2 + bxy + cy^2,$$

u is a function of the independent variables x and y.

The variety of forms of functions of a variable is endless. They may, however, be resolved into a few elementary functions such as these,

$$x^n, \quad a^x, \quad \log x, \quad \sin x, \quad \cos x.$$

The first of these, x^n, in which n is constant, and all that can be formed from it by a finite number of the elemen-

tary operations of algebra, are called *algebraic* functions; for example, this,

$$u = ax^3 + \frac{bx^2 - c^2x}{\sqrt{a^2 + x^2}},$$

which is formed by addition, subtraction, multiplication, division, and the extraction of the square root. These two, a^x, $\log x$, which cannot be expressed by a finite number of terms composed of powers of x, are called *transcendental* functions, and the remaining two, $\sin x$, $\cos x$, and such as may be formed from them, viz. $\tan x$, $\sec x$, &c. are called *trigonometrical*, also *angular* and *circular* functions.

In the last example, the value of the function u may be immediately found, if the value of x be known. Such functions are called *explicit*. There are functions, however, which require to be separated from the variable by the resolution of equations, or other means, before their value can be found; as in this example,

$$ux = \frac{u + x}{u - x},$$

in which u is supposed to be a function of x. In this case, before the value of u, corresponding to a given value of x, can be found, a quadratic equation must be resolved. Such a function is called an *implicit* function of x. On the other hand, x is an implicit function of u. By the resolution of an equation we find

$$u = \frac{1}{2}\left\{x + \frac{1}{x} + \frac{\sqrt{x^4 + 6x^2 + 1}}{x}\right\};$$

u is now an explicit function of x.

The early algebraists indicated the square root of a quantity by placing the letter r before it; thus rx meant the square root of x. The letter was afterwards changed into the sign $\sqrt{}$, and the square root of x was conveniently expressed thus, $\sqrt{x}$. In like manner, it is convenient to have a symbol which shall express generally a function of a variable, and accordingly it is now usual to express any function of a variable x by the symbol fx or $f(x)$; also by Fx, or φx. Here the letters f, or F, or φ, are considered merely as the abbreviation of the word *function*, and not as a co-efficient to the letter x. In this way we include all these expressions,

$$u = x^n, \quad u = a^x, \quad u = \log x, \quad u = \cos x, \quad u = \sin x,$$

in one general expression, viz. $u = fx$, or $u = f(x)$.

When a function depends on two variable quantities x, y, which are independent of each other, such as this expression,

$$u = ax^2 + bxy + cy^2,$$

we shall express it thus,

$$u = f(x, y).$$

Here we take no notice of the constant quantity a, b, c. A like notation may be applied when three independent variables enter a function.

3. The manner in which we propose to treat this subject requires that the reader should distinctly understand what is meant by a *limit* to the value of a variable function, or a variable ratio. In the elements of geometry it is shown that the area of a circle is less than that of any regular polygon described about it; and that the greater the number of sides of the polygon, the more nearly is its area equal to that of the circle; so that any space being given, however small, a polygon may be described about the circle, which shall differ from it by less than that space. Suppose now a series of polygons to be described about a circle, each having the number of its sides greater than that which preceded it, the double for example. These will approach continually to an equality with the circle as a *limit*, which the series, however far continued, can never absolutely reach in respect of magnitude, but from which some term, and all that follow it, may differ by less than any space assignable.

In like manner, the circle is the limit of the area of all regular polygons inscribed in it; and the circumference of the circle is the limit of the perimeters of regular polygons described in it or about it.

In our article ALGEBRA (sect. 266) it has been shown, that, putting a for an arc of a circle, the fraction $\frac{a}{\sin a}$ is always greater than an unit, but that $\frac{a}{\tan a}$ is always less; farther, that the arc being supposed to decrease continually, these fractions approach to each other, and may differ by less than any assignable quantity; therefore unity, which is always between them, is their common limit. Hence it appears, that of these three quantities, an arc, its sine, and its tangent, the limit of the ratio of any two is that of equality. In the same article it has been shown that the arc a is the limit of the fractions $n \tan. \frac{a}{n}$ and $n \sin \frac{a}{n}$, supposing the number n to be increased continually.

The geometrical series

$$1 + x + x^2 + x^3 \ldots. + x^{n-1}$$

is equivalent to the function $\frac{1 - x^n}{1 - x}$ (ALGEBRA, sect. 56); when x is less than 1, and n is infinitely great, then $x^n = 0$, and the function $= \frac{1}{1 - x}$; therefore, in this case, the sum of any finite number of terms of the series will always be less than $\frac{1}{1 - x}$, but will approach to it as the number of terms increases, and may differ from it by less than any assignable quantity; hence it follows that the function $\frac{1}{1 - x}$ is the limit of the sum of the series.

By the binomial theorem

$$\left(1 + \frac{x}{n}\right)^n = 1 + \frac{x}{1} + \frac{x^2}{1\,.\,2}\left(1 - \frac{1}{n}\right)$$
$$+ \frac{x^3}{1\,.\,2\,.\,3}\left(1 - \frac{1}{n}\right)\left(1 - \frac{2}{n}\right) +, \text{ \&c.}$$

This is true, whatever be the numerical value of n; but suppose n to be a large number, then the factors $1 - \frac{1}{n}$, $1 - \frac{2}{n}$, &c. will differ but little from unity; and they will differ the less as n is greater. Suppose now n to be indefinitely great, then these factors may be accounted each equal to an unit; and, therefore,

$$\left(1 + \frac{x}{n}\right)^n = 1 + \frac{x}{1} + \frac{x^2}{1\,.\,2} + \frac{x^3}{1\,.\,2\,.\,3} +, \text{ \&c.}$$

It has been shown in algebra (sect. 177) that the second member of this equation is the development of the function e^x, where e denotes the number 2·7182818, viz. the base of Napier's logarithms; therefore, if n be supposed to increase continually, the expression $\left(1 + \frac{x}{n}\right)^n$ will approach to e^x as its limit; and making $x = 1$, the limit of $\left(1 + \frac{1}{n}\right)^n = e = 2{\cdot}7182818$, a constant quantity.

4. Since the value of a function depends essentially on that of the variable, which is its basis, any change in the value of the latter will produce a corresponding change in the value of the former.

First, let the function be $u = x^2$, and let us suppose that the variable changes its value, being increased by a quantity h, and thereby becoming $x + h$; let u' denote the corresponding value of u, so that we have

$$u' = (x + h)^2 = x^2 + 2xh + h^2 = u + 2xh + h^2;$$

hence $u' - u = 2xh + h^2$.

It thus appears that, h denoting the increment of the variable x, the corresponding increment of the function, viz. $u' - u$, is $2xh + h^2$.

The algebraic expression for a ratio is a fraction whose numerator is the antecedent, and denominator the consequent. In the present case, the ratio of the increment of the function to that of its variable is

$$\frac{u' - u}{h} = 2x + h.$$

As another example, let the function be $u = x^3$; then, supposing, as before, that the variable x is increased by the quantity h, and, putting u' for the new value of the function, we have

$$u' = (x + h)^3 \begin{cases} = x^3 + 3x^2h + 3xh^2 + h^3 \\ = u + 3x^2h + 3xh^2 + h^3; \end{cases}$$

$$\frac{u' - u}{h} = 3x^2 + 3xh + h^2.$$

In this case we see that when x has increased to $x + h$, the function u has become

$$u + 3x^2h + 3xh^2 + h^3,$$

having received the increment $3x^2h + 3hx^2 + h^3$, a quantity composed of the integer powers of h. Farther, it appears that the expression for the ratio of the increments is

$$3x^2 + 3xh + h^2,$$

of which the first term $3x^2$ is entirely independent of the value of h, the increment of x.

When the function is $u = x^4$, we have, putting, as in the former examples, h for the increment of the variable, and u' for the new value of the function,

$$u' = u + 4x^3h + 6x^2h^2 + 4xh^3 + h^4,$$

$$\frac{u' - u}{h} = 4x^3 + 6x^2h + 4xh^2 + h^3.$$

From these examples it appears, that when x changes its value and becomes $x + h$, then the new value of the function

$u = x^2$ becomes $u' = u + 2xh + h^2$,
$u = x^3$ becomes $u' = u + 3x^2h + 3xh^2 + h^3$,
$u = x^4$ becomes $u' = u + 4x^3h + 6x^2h^2 + 4xh^3 + h^4$;

and in general that

$u = x^n$, any integer power of x, becomes
$u' = u + ph + qh^2 + rh^3 + sh^4 +$, &c.

the new value of the function being composed of a series of terms, the first of which is its original value, and the following terms, integer powers of the increment h, multiplied by p, q, r, &c. certain other functions of x, the forms of which depend on the original function, whence they have been derived.

Farther, it appears that

when $u = x^2$, then $\dfrac{u' - u}{h} = 2x + h$;

when $u = x^3$, $\dfrac{u' - u}{h} = 3x^2 + 3xh + h^2$;

when $u = x^4$, $\dfrac{u' - u}{h} = 4x^3 + 6x^2h + 4xh^2 + h^3$;

and, in general, that when $x = u^n$, n being any whole number, then

$$\frac{u' - u}{h} = p + qh + rh^2 + sh^3 +, \text{\&c.}$$

Thus it appears that the expression for $\dfrac{u' - u}{h}$, the ratio of the increment of the function x^n to that of its variable x, may be resolved into two parts, one, p, which is independent of the increment, and another, $qh + rh^2 + sh^3 +$, &c.; or

$$h(q + rh + sh^2 +, \text{\&c.}),$$

which, having h the increment as a factor, must decrease with it, and, by giving a sufficiently small value to h, may become less than any assignable quantity, so that the first term p is the limit of the ratio.

Let us consider the complex function

$$u = a + bx + cx^2.$$

When x becomes $x + h$, u becomes

$$u' = a + b(x + h) + c(x + h)^2$$
$$= a + bx + cx^2 + (b + 2cx)h + ch^2,$$

hence $u' - u = (b + 2cx)h + ch^2$,

$$\frac{u' - u}{h} = b + 2cx + ch.$$

In this case the limit of the ratio is $b + 2cx$. By a like examination of particular functions it will be found that they have all a common property, that is,

If u *be any function of a variable* x, *and if in that function* x *be supposed to change its value and become* x + h; *the corresponding new value of the function will be*

$$u' = u + ph + qh^2 + rh^3 +, \text{\&c.}$$

and the ratio of the increments of the function and its variable,

$$\frac{u' - u}{u} = p + qh + rh^2 +, \text{\&c.};$$

an expression which, when h *is supposed to decrease continually, has for its limit the first term* p; *and this limit will be different for different functions, there being such a connection between the function and its limit, that the one may be found from the other.*

This property of the increments of a function and its variable suggests an important and extensive analytical theory, which will consist of two parts.

I. Any function of a variable quantity being proposed, to determine the limit of the ratio of the corresponding increments of the function and its variable.

II. On the other hand, having given the ratio of the increments, to find the function from which it has been derived.

These two inquiries constitute at bottom the *Direct and Inverse Method of Fluxions* of Newton, the *Differential and Integral Calculus* of Leibnitz, and the *Theory of Functions* of Lagrange. Our present subject is the direct method of fluxions, or its equivalent, the differential calculus.

5. We have seen (4), that by the transition of a function, for example, $u = x^2$, from one state of magnitude to another, by a change in the magnitude of its variable x, it acquires the new value $u' = u + 2xh + h^2$. The *whole difference* $u' - u$ between its new and first values is $2xh + h^2$. It is the first term of this difference, viz. $2xh$, that constitutes what is called the *differential* of the function from which it has been derived; and the determination of this first term for any function is the object of this first part of our calculus.

In like manner, in the function $u = x^3$, which, when x becomes $x + h$, changes to $u' = u + 3x^2h + 3xh^2 + h^3$, the whole difference between the two states of magnitude of the function is $3x^2h + 3xh^2 + h^3$, and its differential is $3x^2h$. And the whole difference between the first and succeeding value of the function $u = x^4$ is $4x^3h + 6x^2h^2 + 4xh^3 + h^4$, and its differential, is $4x^2h$. And, in general, whatever be the nature of the function u, if $x + h$ be substituted in it instead of x, and the expression thus formed be expanded into a series,

$$u + ph + qh^2 + rh^3 + sh^4, \text{\&c.}$$

Direct Method.

the complete difference between the two states of the function is

$$ph + qh^2 + rh^3 + sh^4 +, \&c.$$

and its differential is the first term ph.

In conformity with this definition, the differential of the variable x itself will be its increment h, which, because of its use in generating the differential of the function, has been designated by a peculiar symbol, viz. dx: here the letter d is to be understood as a characteristic, not as a co-efficient. The letter d is also prefixed to the symbol for a function to denote its differential. Thus, supposing $u = x^2$, we have $du = 2xdx$, an expression which means that the differential of the function u is equal to the differential of the variable multiplied by $2x$ as a co-efficient; so also, if $u = x^3$, the equation $du = 3x^2dx$ means that the differential of u is equal to the differential of x multiplied by $3x^2$.

6. Since, when $u = x^2$, then $du = 2xdx$, this last expression may otherwise stand thus, $\frac{du}{dx} = 2x$; under this form $2x$ is the co-efficient in the expression for the differential of u, and it is on that account called the *differential co-efficient* of the function u or x^2. In like manner, when $u = x^3$, then $du = 3x^2dx$ and $\frac{du}{dx} = 3x^2$; in this case $3x^2$ is the differential co-efficient of the function $u = x^3$. The general symbol for the differential co-efficient of any function u is $\frac{du}{dx}$, and the new value of u being $u + ph + qh^2 +$, &c. we have $\frac{du}{dx} = p$, where p is some function of x, which depends on the form of the function u, and is deducible from it when its form is known.

To denote the differential of an expression formed in any way, we prefix the symbol d to the expression. Thus $d\{(a+x)(b^2-x^2)\}$ denotes the differential of a function produced by multiplying the factors $a+x$ and b^2-x^2, and $\frac{d\{(a+x)(b^2-x^2)\}}{dx}$ serves to denote its differential co-efficient.

The definition which has been given of a differential suggests immediately this rule for finding the differential of a function of a single variable.

Substitute x + h *in the function instead of* x; *expand the expression thus formed into a series of terms composed of integer powers of* h, *and take the term which contains the first power of* h *for the differential, exchanging the letter* h *for the symbol* dx.

Thus, let the function be $u = ax + bx^2$, in which a and b are constants, then, putting $x + h$ for x, and u' for the new value of u, we have

$$u' \begin{cases} = a(x+h) + b(x+h)^2 \\ = ax + bx^2 + (a+2bx)h + bh^2 \\ = u + (a+2bx)h + bh^2. \end{cases}$$

Here du, the differential of the function, is $(a+2bx)h$, or $(a+2bx)dx$, and $\frac{du}{dx} = a + 2bx$ the differential co-efficient.

7. The rule given in last article, for determining the differential of a function, supposes that we have methods by which any function may be expanded into a series of terms, into each of which some integer power of the increment h enters only as a factor. It is sufficient for our purpose, however, if we can find that term of the series which contains the simple power of h; and this can in general be found easier than the general development, which indeed may be the very thing to be investigated by the calculus. Now we have seen (4) that the co-efficient of this term is the expression for the limit of the ratio of the corresponding increments of a function and its variable, and the same quantity is the differential co-efficient of the function (6), therefore the determination of the differential of a function is the same thing as the determination of the limit of the ratio of the increments.

Let the function be $u = \frac{a^2}{x}$; then $u' = \frac{a^2}{x+h}$, and

$$u' - u = \frac{a^2}{x+h} - \frac{a^2}{x} = \frac{-a^2h}{x(x+h)};$$

and the limit of the ratio of the increments is

$$\frac{u'-u}{h} = \frac{-a^2}{x(x+h)}.$$

Now, without expanding the expression for the limit, it is obvious that as h decreases, that expression approaches to $-\frac{a^2}{x^2}$, which is therefore $\frac{du}{dx}$, the differential co-efficient of the function; hence $du = -\frac{a^2dx}{x^2}$. In like manner, u being the general expression for any function, and $u' = u + ph + qh^2 +$, &c. its expanded value when $x + h$ is put instead of x, we have

$$\frac{u'-u}{h} = p + qh +, \&c.$$

$$\text{and limit of } \frac{u'-u}{h} = p = \frac{du}{dx}, \text{ and } du = pdx.$$

According to this view of the subject, *the differential calculus is the finding of the ratios of the simultaneous increments of a function and of the variable on which it depends.*

The process of calculation by which the differential of any function u is found, may be regarded as a particular operation performed on quantity, analogous to the elementary operations of algebra; and it may, like these, be distinguished by a particular name accordingly. The result of the process being the *differential*, the process itself is called *differentiation*, and to perform the process on a function is to *differentiate* the function.

8. It is material to observe, that the limit of the ratio of the increments of a function and its variable are the very same, whichever of the two be considered as a function of the other. Thus, u being a function of x, when x becomes $x + h$, u becomes $u + ph + qh^2 + rh^3 +$, &c. p, q, r, &c. being functions of x, deducible from the function u. Let us put

$$k = ph + qh^2 + rh^3 +, \&c.$$

so that the contemporaneous increments of x and u are h and k. Now, from the value of k, by the reversion of series (ALGEBRA, art. 163), we find

$$h = \frac{1}{p}k - \frac{q}{p^3}k^2 +, \&c.$$

So that, regarding x as a function of u, when u becomes $u + k$, x becomes

$$\frac{1}{p}k - \frac{q}{p^3}k^2 +, \&c.$$

and the general expression for the ratio of the increments is

$$\frac{h}{k} = \frac{1}{p} - \frac{q}{p^3}k +, \&c.$$

which has for its limit $\frac{1}{p}$, and the limit of the ratio $\frac{k}{h}$ is, as before, $= p$.

9. It is easy to see that two equal functions must have equal differentials; for whatever be the value of the va-

Direct Method.

riable on which they depend, it must necessarily happen that the respective changes they receive in consequence of the change which is attributed to the variable must also be equal. Thus, if u and v be two functions, such, that $u = v$, whatever may be the value of x; and if, when x becomes $x + h$, then u becomes u', and v becomes v', we shall have $u' = v'$, and $u' - u = v' - v$, and

$$\frac{u' - u}{h} = \frac{v' - v}{h}.$$

If then p and q denote the limits of these ratios, $p = q$ and $pdx = qdx$, that is, $du = dv$.

From this it follows, that under whatever form a function appears, its differential is the very same quantity. For example, the differential of $x^3 + a^3$ will be identical with the differential of $(x + a)(x^2 - ax + a^2)$, its equal.

The converse of this proposition is not generally true, and we should be wrong in affirming that two equal differentials belong to equal functions. For, let $u = a + bx$ be a function of x, then, substituting $x + h$ for x, and putting u' for the new value of u, we have $u' = a + bx + bh = u + bh$, and $\frac{u' - u}{h} = b$.

We see here that the constant a does not enter into the limit of the ratio of the increments, which would therefore be the very same for the function $u = bx$; hence it follows that the differential bdx belongs alike to $a + bx$, and to bx. Thus it appears, that in differentiating any function whatever, all the constant quantities combined with it, either by addition or subtraction, disappear. With respect to those which are connected by multiplication and division, they enter the result as co-efficients.

10. The differential of any function of a variable x may be found by the general methods indicated in article 6; but it is convenient to have rules adapted to particular cases.

Let r and s be two functions of a variable x. It is proposed to investigate a rule for finding the differential of $u = rs$, their product.

Suppose that by the substitution of $x + h$ for x in the functions r and s, and their expansion, they become

$r' = r + ph + qh^2 +$, &c. $s' = s + p'h + q'h^2 +$, &c.

In these expressions, p, q, &c. represent functions of x, derived from r; and p', q', &c. other functions of x derived from s. Corresponding to these let u' denote $r's'$, the new value of the product $rs = u$. By actual multiplication we find

$u' = r's' = rs + (rp' + sp)h + (rq + pp' + sq)h^2 +$, &c.

Hence, putting u for rs, also transposing and dividing by h, there is got

$$\frac{u' - u}{h} = rp' + sp + (rq' + pp' + sq)h +, \&c.$$

The terms rp' and sp in the second member of this equation are functions of x, which are independent of the function h; the following terms are all multiplied by h, therefore they decrease and vanish with it. So that

$$\text{limit of ratio } \frac{u' - u}{h} = rp' + sp.$$

$$\text{Now } p = \text{limit of } \frac{r' - r}{h}, \text{ and } q = \text{limit of } \frac{s' - s}{h}.$$

Instead of the limits of the ratios, let us put the differential co-efficients of the functions u, r, s (art. 6), and we find

$$\frac{du}{dx} = r\frac{ds}{dx} + s\frac{dr}{dx},$$

$$\text{and } du = rds + sdr.$$

Hence we have this rule, *To find the differential of the product of two functions, multiply the differential of each by the differential of the other function, and add the products.*

11. Since, when $u = rs$, we have $du = sdr + rds$, it follows that

$$\frac{du}{u} = \frac{dr}{r} + \frac{ds}{s}.$$

If we suppose $u = rtv$, the product of three factors, by putting $s = tv$, we have $u = rs$, and

$$\frac{du}{u} = \frac{dr}{r} + \frac{ds}{s};$$

but since $s = tv$, we have for the same reason

$$\frac{ds}{s} = \frac{dt}{t} + \frac{dv}{v};$$

$$\text{therefore } \frac{du}{u} = \frac{dr}{r} + \frac{dt}{t} + \frac{dv}{v}.$$

By writing the product rs instead of u, there is got, after proper reduction,

$$du = tvdr + rvdt + rtdv.$$

In general, *If a function be the product of any number of functions of a variable, its differential is the sum of the products obtained by multiplying the differential of each by the product of all the other functions.*

The same rule may also be briefly expressed in symbols, thus: whatever be the number of functions r, s, t, v,

$$d\,(rstv) = rstv\left\{\frac{dr}{r} + \frac{ds}{s} + \frac{dt}{t} + \frac{dv}{v}\right\}.$$

12. To find the differential of a fraction whose numerator and denominator are functions of a variable x; let $u = \frac{r}{s}$, then $r = us$, and

$$dr = uds + sdu,$$

and, putting for u its value $\frac{r}{s}$,

$$dr = \frac{rds}{s} + sdu;$$

$$\text{therefore, } du = \frac{sdr - rds}{s^2}.$$

Hence we have this rule: *To find the differential of a fraction; from the differential of the numerator multiplied by the denominator subtract the differential of the denominator multiplied by the numerator, and divide by the square of the denominator.*

The rule for the differential of $u = \frac{r}{s}$ may be also symmetrically expressed thus:

$$\frac{du}{u} = \frac{dr}{r} - \frac{ds}{s};$$

and in general, if $u = \frac{rst}{vy}$, then

$$\frac{du}{u} = \frac{dr}{r} + \frac{ds}{s} + \frac{dt}{t} - \frac{dv}{v} - \frac{dy}{y}.$$

For, by what has been shown, it appears that when $u = \frac{rst}{vy}$, then

$$\frac{du}{u} = \frac{d(rst)}{rst} - \frac{d(vy)}{vy},$$

$$\text{Now } \frac{d(rst)}{rst} = \frac{dr}{r} + \frac{ds}{s} + \frac{dt}{t},$$

$$\text{and } \frac{d(vy)}{vy} = \frac{dv}{v} + \frac{dy}{y};$$

Direct Method.

therefore, $\frac{du}{u} = \frac{dr}{r} + \frac{ds}{s} + \frac{dt}{t} - \frac{dv}{v} - \frac{dy}{y}$.

It also follows, from what has been shown, that if the numerator of a fraction consist of any number of factors r, s, t, and the denominator of any number v, y, then

$$d\left\{\frac{rst}{vy}\right\} = \frac{rst}{vy}\left\{\frac{dr}{r} + \frac{ds}{s} + \frac{dt}{t} - \frac{dv}{v} - \frac{dy}{y}\right\}.$$

13. We shall next investigate a rule for the differential of any power of a function y, which may be either itself an independent variable, or else some function of another variable.

First, let $u = y^n$, n being any whole number. The function may be put under this form,

$$u = y \cdot y \cdot y \cdot y \ldots \text{ to } n \text{ terms,}$$

and then (11) we have

$$\frac{du}{u} = \frac{dy}{y} + \frac{dy}{y} + \frac{dy}{y} + \frac{dy}{y} \ldots \text{ to } n \text{ terms;}$$

that is, $\frac{du}{u} = \frac{ndy}{y}$,

$$\text{and } du = \frac{ndy}{y} u = ny^{n-1}\, dy.$$

Next, let us suppose that the function has a fractional exponent, and that $u = y^{\frac{m}{n}}$, then $u^n = y^m$,

and $nu^{n-1}\, du = my^{m-1}\, dy$, by art. 9,

$$\text{and } du = \frac{m}{n} \frac{y^{m-1}}{u^{n-1}}\, dy;$$

$$\text{but } u = y^{\frac{m}{n}} \text{ and } u^{n-1} = y^{m - \frac{m}{n}};$$

$$\text{therefore } \frac{y^{m-1}}{u^{n-1}} = y^{\frac{m}{n} - 1},$$

$$\text{and } du = \frac{m}{n} y^{\frac{m}{n} - 1}\, dy$$

Lastly, let us suppose n to be a negative whole number or fraction, so that $u = \frac{1}{y^n}$. In this case we may apply the rule for a fraction (12); and observing that the numerator here is a constant, of which the differential must be accounted $= 0$, we have

$$du = -\frac{ny^{n-1}dy}{y^{2n}} = -ny^{-n-1}dy;$$

thus it appears, that whether n be whole or fractional, positive or negative,

$$d(y^n) = ny^{n-1}dy.$$

Hence this rule: *To differentiate any power of a function, multiply it by the exponent, diminish the exponent by an unit, and multiply by the differential of the variable.*

If the function have a co-efficient, the differential must be multiplied by that co-efficient. Thus

$$d(ax^n) = nax^{n-1}\, dx.$$

The determination of the differential of a power of a variable might have been shortened by assuming the truth of the binomial theorem, as found in our article ALGEBRA, art. 160, 161. That theorem however may be derived from the differential calculus, and we shall give its investigation as one of its applications.

It frequently happens that the differential of $\sqrt{y} = y^{\frac{1}{2}}$, the square root of a function, is to be found; therefore a rule for that case will be convenient. By the general rule for a power,

$$d(y^{\frac{1}{2}}) = \tfrac{1}{2}y^{\frac{1}{2}-1}dy = \tfrac{1}{2}y^{-\frac{1}{2}}dy,$$

$$\text{that is, } d(\sqrt{y}) = \frac{dy}{2\sqrt{y}}.$$

Direct Method.

Hence it appears that *the differential of the square root of a function is the differential of the function divided by twice its square root.*

14. Let y be a function of a variable x, and let u be a function of y; it is proposed to investigate a rule for finding the differential of u relatively to x.

Suppose x to change its value and become $x + h$, then y becomes $y' = y + ph + qh^2 + rh^3 +$, &c.; or, putting $ph + qh^2 + rh^3 +$, &c. $= k$, y becomes $y + k$. But u being a function of y, when y becomes $y + k$, then u becomes $u' = u + p'k + q'k^2 + r'k^3 +$, &c.; here p', q', r', &c. denote certain functions of y, which are independent of k and also of h. Hence, by substituting for k in this last series, its value $ph + qh^2 +$, &c., it appears that when x becomes $x + h$, u becomes

$$u' = u + p'ph + (p'q + q'p^2)\, h^2 +, \&c.$$

$$\text{and hence } \frac{u' - u}{h} = p'p + (p'q + q'p^2)h +, \&c.$$

Suppose now h to decrease continually, we have

$$\text{limit of } \frac{u' - u}{h} = p'p.$$

Now, y being a function of x, $p = \frac{dy}{dx}$, and u being considered as a function of y, $p' = \frac{du}{dy}$; but if we consider u as a function of x, then

$$\frac{du}{dx} = \text{limit } \frac{u' - u}{h} = p'p.$$

Hence it follows that

$$\frac{du}{dx} = \frac{du}{dy} \times \frac{dy}{dx},$$

$$\text{and } du = \left(\frac{du}{dy} \times \frac{dy}{dx}\right)dx.$$

Hence this rule: To find, relatively to x, the differential of u, a function of y, the quantity y being a function of x, *Find the differential co-efficient of* u *considered as a function of* y *only, and the differential co-efficient of* y *considered as a function of* x; *multiply the product of these co-efficients by the differential of* x, *and the result is the differential of* u.

It has been found that

$$\frac{du}{dy} \times \frac{dy}{dx} = \frac{du}{dx};$$

Now if we suppose that $u = x$, then this expression becomes

$$\frac{dx}{dy} \times \frac{dy}{dx} = \frac{dx}{dx} = 1;$$

and hence it appears that

$$\frac{dx}{dy} = \frac{1}{\frac{dy}{dx}}.$$

This shows that the differential co-efficient of x considered as a function of y, is the reciprocal of the differential co-efficient of y considered as a function of x, a conclusion which may also be deduced from art. 8.

15. Let v, y, z be functions of a variable x, and let it be proposed to find the differential of

$$u = a + bv + cy - ez,$$

where a, b, c, e, denote constants.

Let us suppose that when x becomes $x + h$, then

$$v \text{ becomes } v + ph + qh^2 +, \&c.$$
$$y \text{ becomes } y + p'h + qh^2 +, \&c.$$
$$z \text{ becomes } z + p''h + q''h^2 +, \&c.$$

Direct Method.

Let u' be the corresponding value of u, so that

$$u'=\begin{cases}a+bv+cy-ez\\+(bp+cp'-ep'')h\\+(bq+cq'-eq'')h^2\\+,\ \&c.\end{cases}$$

Hence, putting for the first term of the second member of the equation its value u, and transposing and dividing by h, we get

$$\frac{u'-u}{h}=bp+cp'-ep''+(bq+cq'-eq'')h,\ \&c.$$

And passing to the limits, observing that the limit of $\frac{u'-u}{h}$ is the differential co-efficient of u, also that p, p', and p'' are the differential co-efficients of v, y, and z respectively, we get

$$\frac{du}{dx}=\frac{bdv}{dx}+\frac{cdy}{dx}-\frac{edz}{dx},$$

and $du=bdv+cdy-edz$.

From this it appears that *the differential of a function made up of others simply by addition and subtraction is composed in like manner of the differentials of the several terms, each with the sign of the function from which it was derived; the differential of a constant being reckoned* $=0$.

16. These rules are sufficient for the differentiation of any explicit algebraic function, and we shall now give examples.

1. Let $u=ax^5$; this is a particular case of the general function $u=ax^n$; therefore, by the rule (13) $du=5ax^4dx$.

2. Let $u=\frac{a}{x^5}=ax^{-5}$; then $du=-5\,ax^{-6}\,dx=\frac{-5adx}{x^6}$.

3. Let $u=\sqrt{x^3}=x^{\frac{3}{2}}$; in this case $du=\frac{3}{2}x^{\frac{1}{2}}dx=\frac{3}{2}\,dx\sqrt{x}$.

4. Let $u=ax^3+bx^2+cx+e$;
then $du=3ax^2dx+2bxdx+cdx$,
or $du=(3ax^2+2bx+c)\,dx$.

Here the constant e, which is a term of the function, has disappeared by the differentiation.

5. Let $u=(a+bx^n)^p$; we may put $y=a+bx^n$, and then $u=y^p$; and $du=py^{p-1}dy$.

Now $y^{p-1}=(a+bx^n)^{p-1}$, and $dy=bnx^{n-1}dx$;

therefore $du=bnp\,(a+bx^n)^{p-1}x^{n-1}dx$.

We might have dispensed with using the symbol y, and regarded $a+bx^n$ as a single function, and u as a power of that function, and found the differential by the rule of art. 13.

As an example of the rule of art. 10, for the product of two functions,

6. Let $u=x^3\,(a+x)^2$;
put $p=x^3$, and $q=(a+x)^2$; then $u=pq$,
and $du=qdp+pdq$.

Now $dp=3x^2dx$, and $dq=2\,(a+x)\,dx$;
therefore $du=3x^2\,(a+x)^2\,dx+2x^3\,(a+x)\,dx$
$=x^2\,(a+x)\,(3a+5x)\,dx$.

In practice, the introduction of the symbols p and q may be omitted.

7. Let $u=x\,(1+x)\,(1+x^2)$. In this case, u is the product of three functions; therefore, by the rule of art. 11,
$du=(1+x)\,(1+x^2)\,dx+x\,(1+x^2)\,dx+2x^2\,(1+x)\,dx$.
This, when abbreviated by multiplication, becomes
$du=(1+2\,x+3x^2+4x^3)\,dx$.

We might have proceeded otherwise by the rule

$$d\,(rst)=rst\left\{\frac{dr}{r}+\frac{ds}{s}+\frac{dt}{t}\right\};$$

accordingly, we would have had

$$du=x(1+x)\,(1+x^2)\left\{\frac{dx}{x}+\frac{dx}{1+x}+\frac{2xdx}{1+x^2}\right\},$$

an expression reducible to the former.

8. As an example of a fractional function, let $u=\frac{x}{1+x^2}$; we have, following the rule of art. 12,

$$du=\frac{(1+x^2)\,dx-2\,x^2dx}{(1+x^2)^2}=\frac{(1-x^2)dx}{(1+x^2)^2}.$$

9. Again, let $u=\frac{x^3+x}{x^4-x^2+1}=\frac{x(x^2+1)}{x^4-x^2+1}$; this may exemplify the rule

$$d\left(\frac{rs}{t}\right)=\frac{rs}{t}\left\{\frac{dr}{r}+\frac{ds}{s}-\frac{dt}{t}\right\}.$$

Accordingly, making $x=r$, $x^2+1=s$, $x^4-x^2+1=t$, we have

$$du=\frac{x^3+x}{x^4-x^2+1}\left\{\frac{dx}{x}+\frac{2xdx}{1+x^2}-\frac{(4x^3-2x)\,dx}{x^4-x^2+1}\right\}.$$

This by reduction becomes

$$du=\frac{-\{x^6+4x^4-4x^2-1\}dx}{(x^4-x^2+1)^2}.$$

10. As an example of the rule in art. 14, let $u=3y^2$, and $y=x^3+ax$; then

$$\frac{du}{dy}=6y,\ \frac{dy}{dx}=3x^2+a;$$

$$\frac{du}{dy}\cdot\frac{dy}{dx}=6y\,(3x^2+a)=18\,x^2y+6ay,$$

$$\text{and } du=\frac{du}{dy}\cdot\frac{dy}{dx}\cdot dx=18x^2ydx+6aydx.$$

We may in such an example proceed otherwise, thus;
because $u=3y^2$, $du=6ydy$;
and since $y=x^3+ax$, $dy=3x^2dx+adx$,
substitute this value of dy in the expression for du, and it becomes

$$du=18x^2ydx+6aydx,$$

the same as before.

17. The subjects which are to follow require the application of the binomial theorem, we shall therefore give its investigation, as the first application of the calculus.

Supposing n to be any number whatever, whole or fractional, positive or negative, it is easy to infer, from the consideration of particular cases, that

$(1+x)^n=1+\mathrm{A}x+\mathrm{B}x^2+\mathrm{C}x^3+\mathrm{D}x^4+$, &c.,
the co-efficients A, B, C, &c., in the series being numbers altogether independent of x, and deducible from the index n alone. The expression $(1+x)^n$ and its development being equal for all values of x, they form an identical equation, and must have equal differentials, hence (art. 9) we have, taking the differential of each term,
$n(1+x)^{n-1}dx=\mathrm{A}dx+2\mathrm{B}xdx+3\mathrm{C}x^2dx+4\mathrm{D}x^3dx+$, &c.
Leaving now dx out of each term, and multiplying both sides by $1+x$, the result is
$n(1+x)^n=\mathrm{A}+(\mathrm{A}+2\mathrm{B})x+(2\mathrm{B}+3\mathrm{C})x^2+(3\mathrm{C}+4\mathrm{D})x^3$ $+$, &c.

But from the assumed series we have

$$n(1+x)^n=n+n\mathrm{A}x+n\mathrm{B}x^2+n\mathrm{C}x^3+,\ \&c.$$

Now the terms of these two expansions of $n(1+x)^n$ must be identical; therefore

$$\left.\begin{aligned}\mathrm{A}&=n,\\ \mathrm{A}+2\mathrm{B}&=n\mathrm{A},\\ 2\mathrm{B}+3\mathrm{C}&=n\mathrm{B},\\ 3\mathrm{C}+4\mathrm{D}&=n\mathrm{D},\\ \&\text{c}.\end{aligned}\right\}\text{and hence}\left\{\begin{aligned}\mathrm{A}&=n;\\ \mathrm{B}&=\frac{(n-1)}{2}\mathrm{A};\\ \mathrm{C}&=\frac{n-2}{3}\mathrm{B};\\ \mathrm{D}&=\frac{n-3}{4}\mathrm{C};\\ \&\text{c}.\end{aligned}\right.$$

Direct Method.

By substituting for A its value in B, and for B the resulting value in C, and so on, there is found

$$(1+x)^n=1+\frac{n}{1}x+\frac{n(n-1)}{1\ .\ 2}x^2+\frac{n(n-1)(n-2)}{1\ .\ 2\ .\ 3}x^3+\&c.$$

and again, by putting $\frac{v}{a}$ instead of x, and multiplying both sides of the equation by a^n, we get

$$(a+x)^n=a^n+\frac{n}{1}a^{n-1}x+\frac{n(n-1)}{1\ .\ 2}a^{n-2}x^2$$
$$+\frac{n(n-1)(n-2)}{1\ .\ 2\ .\ 3}a^{n-3}x^3+,\ \&c.$$

18. In the investigation of the binomial theorem we have employed a principle of analysis of continual use in the calculus, namely, that in such an equation as this (called an *Identical Equation*),

$a+bx+cx^2+ex^3+\&c.,=A+Bx+Cx^2+Ex^3+\&c.$ (1.)

in which a, b, c, &c., A, B, C, &c. are constants, and x is variable; in order that the equation may hold universally true, it is necessary that $a=A$, $b=B$, $c=C$, $e=E$, &c. For since x is indeterminate, we may suppose it to decrease until it vanish; then all the terms into which it enters also vanish, and we have $a=A$; therefore, leaving these equal terms out of both sides of (1), and dividing all the remaining terms by x, we get

$b+cx+ex^2+,\&c.,=B+cx+Ex^2+,\&c.$ (2.)

By proceeding with this equation as with the former, we obtain $b=B$, $c=C$, $e=E$, &c., and so on.

19. We come now to the investigation of the differentials of transcendental functions of a variable, and begin with the exponential function $u=a^x$, the exponent x being variable, and the quantity a constant. Assuming that when x becomes $x+h$, u becomes u', we have

$$u=a^x,\quad u'=a^{x+h}=a^x\ a^h;$$

therefore, $u'-u=a^x\ a^h-a^x=a^x(a^h-1)$;

$$\text{and } \frac{u'-u}{h}=a^x\frac{a^h-1}{h}.$$

The determination of the limit of the ratio of the increments requires that we determine the limit to which the value of the fraction $\frac{a^h-1}{h}$ tends when h is supposed to decrease continually. Let us put $a=1+c$; by the binomial theorem (art. 17),

$$a^h=(1+c)^h=1+hc+\frac{h(h-1)}{1\ .\ 2}c^2+\frac{h(h-1)(h-2)}{1\ .\ 2\ .\ 3}c^3+\&c.$$

therefore, $\frac{ah-1}{h}=c+\frac{h-1}{2}c^2+\frac{(h-1)(h-2)}{2\ .\ 3}c^3+\&c.$

Now h being supposed to decrease continually, the second side of this formula manifestly approaches to

$$c-\tfrac{1}{2}c^2+\frac{-1\ .-2}{2\ .\ 3}c^3+\frac{-1\ .-2\ .-3}{2\ .\ 3\ .\ 4}c^4+\&c.$$

that is, to $c-\frac{1}{2}c^2+\frac{1}{3}c^3-\frac{1}{4}c^4+,\&c.$

$=(a-1)-\frac{1}{2}(a-1)^2+\frac{1}{3}(a-1)^3-\frac{1}{4}(a-1)^4+,\&c.$

Now it has been shown in ALGEBRA (art. 173), and will be proved in the sequel, that this series expresses Napier's logarithm of the number a. Therefore,

$$\text{limit of } \frac{a^h-1}{h}=\text{Nap. log } a,$$

and hence, $\frac{du}{dx}=\text{limit}\frac{u'-u}{h}=a^x(\text{Nap. log } a)$,

$$\text{and } du=(\text{Nap. log } a)\ a^x dx.$$

We have now this rule for differentiating a function which is a variable power of a constant quantity.

Multiply the function by the differential of the variable index, and by Napier's log. of the constant quantity.

Note.—The logarithm of a number a, in any system whatever, will in what follows be expressed by the abbreviation log a; but when the system is that of Napier, we shall denote it thus, l. a.

20. To find the differential of the transcendental $u=\log x$, the base of the system being a. By the definition of a logarithm (ALGEBRA, art. 165),

$$x=a^u,$$

and, supposing that x becomes $x+h$, and that u becomes u',

$$x+h=a^{u'};$$

therefore, $h=a^{u'}-a^u=a^u(a^{u'-u}-1)=x(a^{u'-u}-1)$;

and hence, making $k=u'-u$,

$$\frac{h}{u'-u}=\frac{x(a^k-1)}{k};$$

$$\text{and } \frac{u'-u}{h}=\frac{1}{x}\cdot\frac{k}{a^k-1}.$$

Passing now to the limits of the two sides of the equation, and observing (as was proved in last article) that k being supposed to decrease continually,

$$\text{limit of } \frac{k}{a^k-1}=\frac{1}{\text{l.}\,a},$$

$$\text{we have } \frac{du}{dx}=\frac{1}{\text{l.}\,a}\cdot\frac{1}{x}.$$

Let M denote the constant factor, viz. the reciprocal of Napier's logarithm of the base of the system of logarithms, which is the modulus of the system (ALGEBRA, art. 172), and we have

$$du=\frac{Mdx}{x};$$

That is, *The differential of the logarithm of a number is found by multiplying the differential of the number by the modulus of the system and dividing by the number.*

Note.—In Napier's system M = 1.

21. The differentials of the trigonometrical functions $\sin x$ and $\cos x$ are next to be investigated.

Let $u=\sin x$, and $u'=\sin(x+h)$; then (ALGEBRA, 240),

$u'-u=\sin(x+h)-\sin x=2\cos(x+\frac{1}{2}h)\sin\frac{1}{2}h$,

$$\text{and } \frac{u'-u}{h}=\cos(x+\tfrac{1}{2}h)\frac{\sin.\frac{1}{2}h}{\frac{1}{2}h}.$$

Observing now that h being understood to decrease continually until it vanish, the limit of $\cos(x+\frac{1}{2}h)$ is $\cos x$, and the limit of $\frac{\sin\frac{1}{2}h}{\frac{1}{2}h}=1$ (ALGEBRA, 266), we have

$$\frac{du}{dx}=\text{limit}\frac{u'-u}{h}=\cos x;$$

$$\text{and } du=dx\cos x.$$

Next let $u=\cos x$, and $u'=\cos(x+h)$ we have now

$u'-u=\cos(x+h)-\cos x=-2\sin(x+\frac{1}{2}h)\sin\frac{1}{2}h$;

$$\frac{u'-u}{h}=-\sin(x+\tfrac{1}{2}h)\frac{\sin\frac{1}{2}h}{\frac{1}{2}h}.$$

Passing now to the limits by supposing h to decrease continually,

$$\frac{du}{dx}=\text{limit}\frac{u'-u}{h}=-\sin x;$$

$$\text{and } du=-dx\sin x.$$

Hence it appears that *The differential of the sine of an arc is the product of the differential of the arc and its cosine:*

Direct Method.

and that the differential of the cosine is the product of the differential of the arc and its sine with the sign — prefixed.

Note.—The negative sign indicates, that while the arc increases the cosine decreases when it is positive.

The differential of the cosine might have been found otherwise, by regarding it as a function of the sine. Thus, putting v for the sine, and y for the cosine; because $y^2 = 1 - v^2$, by differentiating, $ydy = -vdv$; now x being the arc, $dv = ydx$; therefore $ydy = -vydx$, and $dy = -vdx$.

22. The functions $u = \tan x$, $u = \cot x$, &c. may be considered as formed from the elementary functions sin x and cos x.

(1.) Let $u = \tan x = \frac{\sin x}{\cos x}$, then (art. 12 and 20),

$$du = \frac{d(\sin x)\cos x - d(\cos x)\sin x}{\cos^2 x}$$

$$= \frac{(\cos^2 x + \sin x^2)dx}{\cos^2 x} = \frac{dx}{\cos^2 x}.$$

Hence, again, $du = dx \sec^2 x = dx(1 + \tan^2 x)$.

(2.) In the same way, if $u = \cot x$, we find

$$du = \frac{-dx}{\sin x^2} = -dx \operatorname{cosec}^2 x = -dx(1 + \cot^2 x).$$

(3.) Let $u = \sec x = \frac{1}{\cos x}$; then

$$du = \frac{dx \sin x}{\cos^2 x} = dx \tan x \sec x.$$

(4.) Let $u = \operatorname{cosec} x = \frac{1}{\sin x}$;

$$du = -\frac{dx \cos x}{\sin^2 x} = -dx \cot x \operatorname{cosec} x.$$

23. Corresponding to the direct functions

$u = \sin x$, $u = \cos x$, &c.

there are the reverse functions,

$u = \text{arc}(\sin = x)$, $u = \text{arc}(\cos x)$, &c.

The first, viz. the arc whose sine is x, is sometimes by British writers expressed thus; $u = \sin^{-1}x$; and the second, the arc whose cosine is x, thus; $u = \cos^{-1}x$.

(1.) Let $u = \text{arc}(\sin = x) = \sin^{-1}x$;

then $x = \sin u$; and $dx = du \cos u = du\sqrt{1-x^2}$;

$$\text{and } du = \frac{dx}{\sqrt{1-x^2}}.$$

(2.) Let $u = \text{arc}(\cos = x) = \cos^{-1}x$:

then $x = \cos u$; and $dx = -du \sin u = -du\sqrt{1-x^2}$;

$$\text{and } du = \frac{-dx}{\sqrt{1-x^2}}.$$

(3.) Let $u = \text{arc}(\tan = x) = \tan^{-1}x$:

then $x = \tan u$ and $dx = du(1 + x^2)$;

$$\text{and } du = \frac{dx}{1+x^2}.$$

(4.) Let $u = \text{arc}(\cot = x) = \cot^{-1}x$;

then $x = \cot u$ and $dx = -du(1 + u^2)$,

$$\text{and } du = \frac{-dx}{1+x^2}.$$

(5.) Let $u = \text{arc}(\sec = x) = \sec^{-1}x$;

then $x = \sec u$; and $dx = du \sec u \tan u = du\,x\sqrt{x^2-1}$,

$$\text{and } du = \frac{dx}{x\sqrt{x^2-1}}.$$

(6.) Let $u = \text{arc}(\operatorname{cosec} = x) = \operatorname{cosec}^{-1}x$,

then, proceeding as in the foregoing examples, we find

$$du = \frac{-dx}{x\sqrt{x^2-1}}.$$

24. Having now found rules for the differentiation of the elementary transcendentals and trigonometrical functions, we proceed to exemplify their application to the differentiation of complex functions.

(1.) Let the function be $u = x^y$, that is a variable x raised to a power y, a function of the variable.

By the theory of logarithms $\text{l.}\,u = y\,\text{l.}\,x$.

Put $v = \text{l.}\,u$ and $z = \text{l.}\,x$; then $v = yz$;

and $dv = ydz + zdy$ (art. 10).

Now $dv = d(\text{l.}u) = \frac{du}{u}$; and $dz = d(\text{l.}x) = \frac{dx}{x}$ (20);

$$\text{therefore, } \frac{du}{u} = \frac{ydx}{x} + \text{l.}\,x\,.\,dy,$$

$$\text{and } du \begin{cases} = u\left\{\frac{y}{x}dx + \text{l.}\,x\,.\,dy\right\} \\ = x^y\left\{\frac{y}{x}dx + \text{l.}\,x\,.\,dy\right\} \\ = x^{y-1}\,ydx + x^y\,\text{l.}\,x\,.\,dy. \end{cases}$$

(2.) If $u = x^x$, then, by last example,

$$du = x^x\left\{1 + \text{l.}\,x\right\}dx.$$

(3.) Let $u = a^{b^x}$; put $b^x = y$, then $u = a^y$,

and $du = \text{l.}\,a\;a^y dy$, also $dy = \text{l.}\,b\,.\,b^x\,dx$ (19);

therefore $du = \text{l.}\,a.\,\text{l.}\,b.\,a^{b^x}\,b^x\,dx$.

In the following examples we shall suppose the logarithms to be those of Napier's system.

(4.) Let $u = \text{l.}\left\{\frac{x}{\sqrt{a^2+x^2}}\right\}$. Making $\frac{x}{\sqrt{a^2+x^2}} = z$,

we have $du = \frac{dz}{z}$; but

$$dz = \frac{dx\sqrt{a^2+x^2} - \frac{x^2dx}{\sqrt{a^2+x^2}}}{a^2+x^2} = \frac{a^2dx}{(a^2+x^2)^{\frac{3}{2}}};$$

$$\text{therefore } du = \frac{a^2dx}{x(a^2+x^2)}.$$

(5.) Let $u = \text{l.}\left\{\frac{\sqrt{1+x}+\sqrt{1-x}}{\sqrt{1+x}-\sqrt{1-x}}\right\}$;

put $y = \sqrt{1+x} + \sqrt{1-x}$, $z = \sqrt{1+x} - \sqrt{1-x}$;

then $u = \text{l.}\left(\frac{y}{z}\right) = \text{l.}\,(y) - \text{l.}\,(z)$;

$$\text{and } du = \frac{dy}{y} - \frac{dz}{z}.$$

$$\text{Now } dy = \frac{dx}{2\sqrt{1+x}} - \frac{dx}{2\sqrt{1-x}}$$

$$= \frac{-dx}{2\sqrt{1-x^2}}\left\{\sqrt{1+x} - \sqrt{1-x}\right\} = \frac{-zdx}{2\sqrt{1-x^2}},$$

$$\text{and } dz = \frac{dx}{2\sqrt{1+x}} + \frac{dx}{2\sqrt{1-x}}$$

$$= \frac{dx}{2\sqrt{1-x^2}}\left\{\sqrt{1+x} + \sqrt{1-x}\right\} = \frac{ydx}{2\sqrt{1-x^2}};$$

$$\text{therefore } \frac{dy}{y} - \frac{dz}{z} = \frac{-zdx}{2y\sqrt{1-x^2}} - \frac{ydx}{2z\sqrt{1-x^2}}$$

$$=\frac{-(y^2+z^2)dx}{2yz\sqrt{1-x^2}};$$

and observing that

$$y^2+z^2=4,\quad yz=2x,$$

we find at last $du=\dfrac{-dx}{x\sqrt{1-x^2}}$.

In the next two examples we shall merely put down the results

(6.) $$u=\mathrm{l}.\left\{x+\sqrt{1+x^2}\right\}$$

$$du=\frac{dx}{\sqrt{1+x^2}},$$

(7.) $$u=\mathrm{l}\cdot\left\{\frac{\sqrt{1+x^2}+x}{\sqrt{1+x^2}-x}\right\}^{\frac{1}{2}}$$

$$du=\frac{dx}{\sqrt{1+x^2}}.$$

25. As examples combining logarithmic and angular functions:

(1.) Let $u=\mathrm{l.}\sin x$;

then $du=\dfrac{dx\cos x}{\sin x.}=dx\,\mathrm{cotan}\,x.$

(2.) Let $u=\mathrm{l.}(\tan x)$;

$$du\begin{cases}=\dfrac{dx\sec^2 x}{\tan x}=\dfrac{dx}{\sin x\cos x}\\[2mm] =\dfrac{2dx}{\sin 2x}.\end{cases}$$

26. As examples of complex angular functions:

(1.) Let $u=\tan^{-1}x$; that is, let u be the arc whose tangent is x, and let $z=\cos nu\cos^n u$.

It is proposed to find the differential co-efficient $\dfrac{dz}{dx}$.

In the first place, $du=\dfrac{dx}{\sec^2 u}=dx\cos^2 u$,

$$dz\begin{cases}=-ndu\,(\sin nu\cos^n u+\cos nu\sin u\cos^{n-1}u)\\ =-ndu\cos^{n-1}u\cdot(\sin nu\cos u+\cos nu\sin u)\\ =-ndu\cos^{n-1}u\sin(n+1)u,\end{cases}$$

and $\dfrac{dz}{dx}=-n\sin(n+1)u\cos^{n+1}u.$

(2.) Next, u being the same function of x as before,

let $z=\sin nu\cos^n u$,

to find the differential co-efficient $\dfrac{dz}{dx}$.

In this case,

$$dz\begin{cases}=ndu\,(\cos nu\cos^n u-\sin nu\sin u\cos^{n-1}u)\\ =ndu\cos^{n-1}u\,(\cos nu\cos u-\sin nu\sin u)\\ =ndu\cos^{n-1}u\cos(n+1)u,\end{cases}$$

and $\dfrac{dz}{dx}=n\cos(n+1)u\cos^{n+1}u.$

Successive Differentiations.

27. A function of a variable, when differentiated, produces a new function, viz. its differential co-efficient. This in its turn may be differentiated, and there will be produced another differential co-efficient, which will stand in the same relation to the former as that did to the original function. By another differentiation, a third differential co-efficient may be formed; and so on continually, unless some differential co-efficient come out $=0$.

For example, from the function $u=x^n$, we deduce $\dfrac{du}{dx}=n\,x^{n-1}$: putting now $p=nx^{n-1}$, we hence derive the differential co-efficient $\dfrac{dp}{dx}=n(n-1)x^{n-2}$; and putting $q=n(n-1)x^{n-2}$, we find $\dfrac{dq}{dx}=n(n-1)(n-2)x^{n-3}$. We may proceed in this way, until the result of a differentiation be a constant, and then the process will stop; but in some cases it may be continued indefinitely.

There is an appropriate notation to express the relation in which the successive differentials, p, q, &c. stand to the original function u, from which they have been derived: since

$$p=\frac{du}{dx},\ \text{and}\ q=\frac{dp}{dx},\ \text{therefore}\ q=\frac{d\left(\frac{du}{dx}\right)}{dx}:$$

The symbol $d\left(\dfrac{du}{dx}\right)$ will be more simply expressed by $\dfrac{d^2u}{dx}$; and thus we have

$$p=\frac{du}{dx},\ q=\frac{dp}{dx}=\frac{d^2u}{dx^2};$$

so that by the expression $q=\dfrac{d^2u}{dx^2}$, it is to be understood that q is the result of two differentiations performed on the function u, the differential of the variable, viz. dx, being considered as constant.

From the function q we may now deduce

$$r=\frac{dq}{dx}=\frac{d^3u}{dx^3},$$

and so on continually; but the different import of the characters d^3u and dx^3 must be carefully attended to; the former implies that the operation of differentiation has been performed three times on the function u, and the latter denotes the third power of dx. The combination of the two, $\dfrac{d^3u}{dx^3}$, expresses the function that results from the three differentiations, in each of which the factor dx has been left out, and the final result divided by its third power, or, if retained, that it has been regarded as constant.

(1.) As a particular case of the function $u=ax^n$, let $u=ax^5$;

$$\text{then}\ \frac{du}{dx}=5ax^4,\quad \frac{d^2u}{dx^2}=4\cdot5ax^3,$$
$$\frac{d^3u}{dx^3}=3\cdot4\cdot5ax^2,\quad \frac{d^4u}{dx^4}=2\cdot3\cdot4\cdot5ax,$$
$$\frac{d^5u}{d^5x}=2\cdot3\cdot4\cdot5a.$$

In this example we have come to a differential co-efficient which is a constant, and the series stops; but if the index of the power x^n be a fraction or negative, the series may be continued indefinitely.

The expression $\dfrac{du}{dx}$ is called the *first* differential co-efficient of the function u, or the differential co-efficient of the *first order*; those which follow are called the *second*, *third*, &c. or the differential co-efficients of the *second*, *third*, &c. orders.

In the case of the function $u=x^5$, writers on the calculus of fluxions call $du=5x^4dx$ the *first* fluxion of the function; $d^2u=20x^3dx^2$ its *second* fluxion; $d^3u=60x^2dx^3$ its *third* fluxion; and so on, the terms of the series constituting the different *orders* of fluxions.

Direct Method.

Other examples of successive differentiation:

(2.) Let $u = a^x$; then (article 9), $\frac{du}{dx} = 1.a\,a^x$,

$\frac{d^2u}{dx^2} = (1.a)^2\,a^x$, $\frac{d^3x}{dx^3}\,(1.a)^3\,a^x$, $\frac{d^4x}{dx^4} = (1.a)^4\,a^x$, &c.

(3.) Let $u = \log. x$; then (art. 20) $\frac{du}{dx} = \frac{M}{x}$,

$\frac{d^2u}{dx} = -\frac{M}{x^2}$, $\frac{d^3u}{dx^3} = +\frac{1\cdot 2M}{x^3}$, $\frac{d^4u}{dx^4} = -\frac{1\cdot 2\cdot 3M}{x^4}$, &c.

(4.) Let $u = \sin x$; then $\frac{du}{dx} = \cos x$,

$\frac{d^2u}{dx^2} = -\sin x$, $\frac{d^3u}{dx^3} = -\cos x$, $\frac{d^4u}{dx^4} = \sin x$, &c.

(5.) Let $u = \cos x$; then $\frac{du}{dx} = -\sin x$,

$\frac{d^2u}{dx^2} = -\cos x$, $\frac{d^3u}{dx^3} = \sin x$, $\frac{d^4u}{dx^4} = \cos x$, &c.

(6.) Let $u = \frac{a^2}{a^2 + x^2}$; then $\frac{du}{dx} = \frac{-2a^2x}{(a^2+x^2)^2}$,

$$\frac{d^2u}{dx^2} = \frac{-2a^4 + 6a^2x^2}{(a^2+x^2)^3},$$

$$\frac{d^3u}{dx^3} = \frac{24a^4x - 24a^2x^3}{(a^2+x^2)^4}, \text{ \&c.}$$

Taylor's Theorem.

28. We have assumed for the foundation of the differential calculus an important analytical principle, first particularly recognised by Euler, viz. Let $f(x)$ denote any function of a variable quantity x; if instead of x there be substituted $x + h$, h being any indeterminate quantity, so that the function becomes $f(x + h)$, this new value may always be expanded into a series of this form,

$$f(x) + ph + qh^2 + rh^3 +, \text{\&c.},$$

in which the quantities p, q, &c. are new functions of x derived from the primitive function, and independent of the indeterminate quantity h.

29. The truth of this principle has been exemplified by induction from particular cases. Lagrange has, however, given a demonstration of it in his *Théorie des Fonctions*, which is to the following effect:

In the first place, the development of the function $(x + h)$ cannot contain any fractional power of h, so long as x is entirely indeterminate. For the radicals of h can only come from radicals in the primitive function; and it is manifest that the substitution of $x + h$ instead of x can neither increase nor diminish their number, nor change their nature, while x and h are indeterminate. On the other hand, by the theory of equations, every radical expression has as many different values as there are units in its exponent; from which it follows, that every irrational function has as many distinct values as there are combinations of the different values of the radicals which it contains. Therefore, if the development of the function $f(x + h)$ could contain a term of the form $uh^{\frac{m}{n}}$, the function fx must necessarily be irrational, and contain a certain number of different values, which must be the same for its development; but this development being represented by the series $f(x) + ph + qh^2 +$, &c. $+ uh^{\frac{m}{n}} +$, &c. every value of the function $f(x)$ (the first term) might be combined with each of the n values of the radical $\sqrt[n]{x^m}$, so that the function $f(x + h)$ expanded would have more values than the same function unexpanded, which is impossible.

This demonstration is general and rigorous so long as x and h continue indeterminate; but it fails if determinate values be given to x, for it may happen that these values may destroy some radicals in the function $f(x)$, which may yet exist in the function $f(x + h)$.

30. It being proved that the development of the function cannot have any fractional powers of h, it is easy to be assured that it cannot contain negative powers. For if among the terms one had the form $\frac{r}{h^m}$, m being a positive integer number, then, in making $h = 0$, that term would become infinite, and the function $(x + h)$, and of course $f(x)$, would in this case be infinite, which cannot be, unless a particular value be given to x. Thus it is clearly established that the development of the function can contain neither fractional nor negative exponents.

31. The general form of the development of the function, viz.

$$f(x + h) = f(x) + ph + qh^2 + rh^3 +, \text{\&c.}$$

being thus ascertained, the next question is, what is the law of relation between the original function $f(x)$ and the functions p, q, r, &c. which are derived from it? We owe the discovery of this relation to a celebrated English mathematician, Brooke Taylor, who gave it in his *Methodus Incrementorum*, published in the year 1715 in the form of an analytical theorem, which is now called by his name: we shall now give its investigation. The following is that of Lagrange.

Let $f(x) = u$ be any function of x;
then, supposing x to become $x + h$, u becomes

$$f(x + h) = u + ph + qh^2 + rh^3 + sh^4 +, \text{\&c.}$$

Suppose now that x changes again its value, and becomes $x + k$, and here k, like h, is independent of x. Then

$$f(x + h) \text{ becomes } f(x + h + k).$$

There are two ways of finding what the series

$$f(x + h) = u + ph + qh^2 + rh^3 + sh^4 +, \text{\&c.}$$

becomes, when $x + h$ becomes $x + h + k$. 1*st*, We may have the value of the series by substituting $h + k$ in every term instead of h. 2*dly*, We may also have its value by substituting $x + k$ in the functions p, q, r, s, &c. for x; that is, instead of p, and q, and r, &c. we must put the values they have when $x + k$ is supposed to be substituted in them instead of x.

By the first-mentioned process we find $f(x + h + k) =$

$$\begin{array}{llllll} u + ph + qh^2 & + rh^3 & + sh^4 & +, \text{\&c.} \\ + pk + 2qhk & + 3rh^2k & + 4sh^3k & +, \text{\&c.} \\ \quad + qk^2 & + 3rhk^2 & + 6sh^2k^2 & +, \text{\&c.} \\ & + rk^3 & + 4shk^3 & +, \text{\&c.} \\ & & + sk^4, & +, \text{\&c.} \end{array}$$

And, in employing the second, it must be considered that, when x becomes $x + k$, then

$$u \text{ becomes } u + pk + qk^2 + rk^3 + sk^4 +, \text{\&c.}$$

because k here takes the place of h in the function $f(x + h)$, and its development $u + ph + qh^2 + rh^3 +$, &c.

The supposition that x changes its value to $x + k$, leads to corresponding changes in the functions p, q, r, &c.; so that

$$\begin{array}{ll} p \text{ becomes} & p + p'k + p''k^2 + p'''k^3 +, \text{\&c.} \\ q \quad . \; . \; . & q + q'k + q''k^2 + q'''k^3 +, \text{\&c.} \\ r \quad . \; . \; . & r + r'k + r''k^2 + r'''k^3 +, \text{\&c.} \\ s \quad . \; . \; . & s + s'k + s''k^2 + s'''k^3 +, \text{\&c.} \\ \text{\&c.} & \end{array}$$

Direct Method.

Here p', p'', &c. denote functions of x derived from p, just as p, q, r, &c. are derived from the function u; and a like remark applies to q', q'', &c. also to r', r'', &c. and so on. Substituting now these new values of u, p, q, r, &c. in the series $u + ph + qh^2 + rh^3 + sh^4 +$, &c. we have $f(x + h + k) =$

$$\begin{aligned} u + pk + qk^2 &+ rk^3 + sk^4 +, \text{\&c.} \\ + ph + p'hk &+ p''hk^2 + p'''hk^3 +, \text{\&c.} \\ + qh^2 &+ q'h^2k + q''h^2k^2 +, \text{\&c.} \\ &+ rh^3 + r'h^3k +, \text{\&c.} \\ &+ sh^4 +, \text{\&c.} \end{aligned}$$

By comparing the co-efficients of like powers, or products of powers, of h and k in the two expressions for $f(x + h + k)$, it appears that, to make them identical, we must have

$$2q = p',\ 3r = q',\ 4s = r', \text{ and so on.}$$

$$\text{Therefore } q = \frac{p'}{2}, r = \frac{q'}{3}, s = \frac{r'}{4}, \text{\&c.}$$

Now, by the definition of a differential, pdx is the differential of u, where p is the co-efficient of h in the series $u + ph + qh^2 +$, &c. Therefore $p = \frac{du}{dx}$. Similarly, $q'dx$ is the differential of q, where q' is the co-efficient of k in the development $q - q'k + q''k^2 +$, &c. Therefore, $q' = \frac{dq}{dx}$; and in like manner, $r' = \frac{dr}{dx}$ and $s' = \frac{ds}{dx}$, and so on; hence

$$p = \frac{dy}{dx},$$

$$q = \tfrac{1}{2}p' = \tfrac{1}{2}\frac{dp}{dx} = \frac{1}{1.2}\frac{d^2u}{dx^2},$$

$$r = \tfrac{1}{3}q' = \tfrac{1}{3}\frac{dq}{dx} = \frac{1}{1.2.3}\frac{d^3u}{dx^3},$$

$$s = \tfrac{1}{4}r' = \tfrac{1}{4}\frac{dr}{dx} = \frac{1}{1.2.3.4}\frac{d^4u}{dx^4},$$

&c.

These values of p, q, r, s, &c. being substituted in the series $u + ph + qh^2 + rh^3 + sh^4 +$, &c. we obtain $f(x + h) =$

$$u + \frac{du}{dx}h + \frac{d^2u}{dx^2}\frac{h^2}{1.2} + \frac{d^3u}{dx^3}\frac{h^3}{1.2.3} + \frac{d^4u}{dx^4}\frac{h^4}{1.2.3.4} +, \text{\&c.}$$

where $u = f(x)$; this is Taylor's theorem.

32. We shall now give another investigation of this important formula, which is remarkable for its brevity and simplicity. It rests on the following analytic principle.

If u *be any function whatever of* v + z, *which relation may be expressed thus,* u = f (v + z); *the differential co-efficient of* u, *found on the supposition that* v *is variable and* z *constant, will be the very same as if it were found on the supposition that* z *is variable and* v *constant.*

To exemplify this in particular cases, suppose $u = (v + z)^n$, then, making v variable and z constant, $\frac{du}{dv} = n(v + z)^{n-1}$; and making z variable and v constant, $\frac{du}{dz} = n(v + z)^{n-1}$, the same as before. Again, let $u = a^{v+z} = a^v\ a^z$, then $\frac{du}{dv}$ and $\frac{du}{dz}$ are expressed by the same quantity $1.a.a^v\ a^z = 1.a.a^{v+z}$.

The truth of the principle is almost self-evident; for if we make $v + z = x$, so that $f(v + z) = f(x)$; then, whether we suppose v to vary and to become $v + h$, while z remains the same, or z to vary and become $z + h$, while v remains constant, the result is the very same, viz.

$$f(v + z + h) = f(x + h);$$

therefore, in the development of $f\ (v + z + h) = f(x + h)$, viz.

$$f(x) + ph + qh^2 + rh^3 +, \text{\&c.}$$

in which p, q, &c. are functions of x; that is, of $v + z$, these functions will be the very same, whichever of the two, v and z, has been considered as the variable, the other remaining constant. Now, by the nature of a differential (art. 7), we have

$$p = \frac{d\{f(x)\}}{dx} = \frac{d\{f(v + z)\}}{d(v + z)};$$

and upon the supposition that v is variable and z constant, then

$$p = \frac{d\{f(v + z)\}}{dv};$$

but supposing z variable and v constant,

$$p = \frac{d\{f(v + z)\}}{dz};$$

$$\text{therefore } \frac{d\{f(v + z)\}}{dv} = \frac{d\{f(v + z)\}}{dz};$$

the first side of this equation being the result of the differentiation, supposing v variable, and the second the result, on the hypothesis that z is variable. Since the two expressions $\frac{d\{f(v + z)\}}{dv}$ and $\frac{d\{(v + z)\}}{dz}$ are identical and the same function of $v + z$, we may represent that function by the symbol $\mathrm{F}(v + z)$; then, by reasoning as before, we shall have

$$\frac{d\{\mathrm{F}(v + z)\}}{dv} = \frac{d\{\mathrm{F}(v + z)\}}{dz},$$

$$\text{that is, } \frac{d^2\{f(v + z)\}}{dv^2} = \frac{d^2\{f(v + z)\}}{dz^2}.$$

Thus it appears that the second differential co-efficient of the function $f(v + z)$ is the same expression, whether v or z be regarded as the variable; and the reasoning may be extended to the co-efficient of any order.

33. Supposing now $f(x) = u$ to be any function of x, and $f(x + h) = u'$ to be its value when x becomes $x + h$, it has been proved (art. 29, 30), that the expansion of u is

$$u' = u + ph + qh^2 + rh^3 + sh^4;$$

and here p, q, r, &c. are functions of x, into which x does not at all enter; while, on the other hand, h is entirely independent of x. From the identity of the function u' and its expansion, their differentials, taken on the same hypothesis, must be equal, whichever of the quantities x and h be regarded as the variable. Supposing, first, x variable and h constant, we have

$$\frac{du'}{dx} = \frac{du}{dx} + \frac{dp}{dx}h + \frac{dq}{dx}h^2 + \frac{dr}{dx}h^3 + \frac{ds}{dx}h^4 +, \text{\&c.}$$

and next, supposing h to be variable and x constant,

$$\frac{du}{dh} = p + 2qh + 3rh^2 + 4sh^3 +, \text{\&c.}$$

Now it has been shown in last article that $\frac{du'}{dx} = \frac{du'}{dh}$; therefore the series which are their expansions must be identical; and hence the terms independent of h must be equal, also the co-efficients of the same power of h, so that

$$p = \frac{du}{dx},\quad 2q = \frac{dp}{dx},\quad 3r = \frac{dq}{dx},\quad 4s = \frac{dr}{dx}, \text{\&c.};$$

and since $p=\frac{du}{dx}$, therefore $q=\frac{1}{2}\frac{dp}{dx}=\frac{1}{2}\frac{d^2u}{dx^2}$, and $r=\frac{1}{3}\frac{dq}{dx}=\frac{1}{2.3}\frac{d^3u}{dx^3}$; also $s=\frac{1}{4}\frac{dr}{dx}=\frac{1}{2.3.4}\frac{d^4u}{dx^4}$, &c.; and, on the whole, $f(x+h)=$

$$u'=u+\frac{du}{dx}h+\frac{d^2u}{dx^2}\frac{h^2}{2}+\frac{d^3u}{dx^3}\frac{h^3}{2.3}+\frac{d^4u}{dx^4}\frac{h^4}{2.3.4}+, \&c.$$

From this formula it appears, that if h be the increment of the variable x; the whole increment of u, any function of x, is

$$u'-u=\frac{du}{dx}\frac{h}{1}+\frac{d^2u}{dx^2}\frac{h^2}{1.2}+\frac{d^3u}{dx^3}\frac{h^3}{1.2.3}+, \&c.$$

a series composed of the successive differential co-efficients of the function, each multiplied by an integer power of h, and divided by the products 1, 1.2, 1.2.3, &c.

Application of Taylor's Theorem to the Development of Functions.

We shall now give some applications of this most important analytic formula to the development of functions.

34. Let the function $f(x)$ be $u=x^n$, so that $f(x+h)=(x+h)^n$. By successive differentiation (art. 13 and 27),

$$\frac{du}{dx}=nx^{n-1},\ \frac{d^2u}{dx^2}=n(n-1)x^{n-2},\ \frac{d^3u}{dx^3}=n(n-1)(n-2)x^{n-3},$$

$$\frac{d^4u}{dx^4}=n(n-1)(n-2)(n-3)x^{n-4}, \&c.$$

These differential co-efficients, when substituted in the formula, give

$$(x+h)^n=x^n+nx^{n-1}h+\frac{n(n-1)}{1.2}x^{n-2}h^2+\frac{n(n-1)(n-2)}{1.2.3}x^{n-3}h^3+, \&c.$$

This is the well-known binomial theorem (ALGEBRA, art. 160).

35. Next, let $f(x)$ be $u=a^x$, a variable power of the constant quantity a. Then, putting

$$A=(a-1)-\tfrac{1}{2}(a-1)^2+\tfrac{1}{3}(a-1)^3-\tfrac{1}{4}(a-1)^4+, \&c.$$

By article 19, $\frac{du}{dx}=Aa^x$, $\frac{d^2u}{dx^2}=A^2a^x$, $\frac{d^3u}{dx^3}=A^3a^x$,

$$\frac{d^4u}{dx^4}=A^4a^x, \&c.$$

Remarking now that $f(x+h)=a^{x+h}=a^x\,a^h$, we have

$$a^x\,a^h=a^x\left\{1+Ah+\frac{A^2h^2}{1.2}+\frac{A^3h^3}{1.2.3}+\frac{A^4h^4}{1.2.3.4}+, \&c.\right\};$$

and dividing both sides by a^x, and changing h into x,

$$a^x=1+Ax+\frac{A^2x^2}{1.2}+\frac{A^3x^3}{1.2.3}+\frac{A^4x^4}{1.2.3.4}+, \&c.$$

If we suppose $x=1$, then,

$$a=1+A+\frac{A^2}{1.2}+\frac{A^3}{1.2.3}+\frac{A^4}{1.2.3.4}+, \&c.$$

and if we make $x=\frac{1}{A}$, we have

$$a^{\frac{1}{A}}=1+1+\frac{1}{1.2}+\frac{1}{1.2.3}+\frac{1}{1.2.3.4}+, \&c.$$

Hence it appears that $a^{\frac{1}{A}}$ is a constant number, which is the sum of this series. By taking the sum of a sufficient number of its terms, we find

$$a^{\frac{1}{A}}=2{\cdot}718281828459.$$

Let this number, which will frequently recur, be denoted by the letter e, and we have

$$a^{\frac{1}{A}}=e, \text{ and } a=e^A \text{ and}$$

$$e^{Ax}=a^x=1+Ax+\frac{A^2x^2}{1.2}+\frac{A^3x^3}{1.2.3}+\frac{A^4x^4}{1.2.3.4}+, \&c.;$$

and making $y=Ax$, so that y may be any number,

$$e^y=1+y+\frac{y^2}{1.2}+\frac{y^3}{1.2.3}+\frac{y^4}{1.2.3.4}+, \&c.$$

This formula expresses a remarkable property of the number e.

36. Let the function $f(x)$ be $u=\log x$ to base a, then, by article 20,

$$\frac{du}{dx}=\frac{1}{Ax},\ \frac{d^2u}{dx^2}=\frac{-1}{Ax^2},\ \frac{d^3u}{dx^3}=\frac{1.2}{Ax^3}, \&c.$$

$$\frac{d^4u}{dx^4}=-\frac{1.2.3}{Ax^4},\ \frac{d^5u}{dx^5}=\frac{1.2.3.4.5}{Ax^5}, \&c.$$

Hence, by the theorem, $f(x+h)=\log(x+h)=\log x+\frac{1}{A}\left\{\frac{h}{x}-\frac{h^2}{2x^2}+\frac{h^3}{3x^3}-\frac{h^4}{4x^4}+\frac{h^5}{5x^5}-, \&c.\right\}$.

Make $x=1$, and observe that $\log 1=0$, and change h into x, and we have

$$\log(1+x)=\frac{1}{A}\left\{x-\tfrac{1}{2}x^2+\tfrac{1}{3}x^3-\tfrac{1}{4}x^4+, \&c.\right\}$$

This is the logarithm of $1+x$ in the system whose base is a.

In the preceding article we found that $a=e^A$, hence, from the theory of logarithms (ALGEBRA, sect. xix.), A is the logarithm of a to the base e. Now

$$A=a-1-\tfrac{1}{2}(a-1)^2+\tfrac{1}{3}(a-1)^3-\tfrac{1}{4}(a-1)^4,+, \&c.$$

Therefore, in the system whose base is e,

$$\log a=a-1-\tfrac{1}{2}(a-1)^2+\tfrac{1}{3}(a-1)^3-\tfrac{1}{4}(a-1)^4;$$

and hence, putting $1+x$ for a, and x for $a-1$, in that system,

$$\log(1+x)=x-\tfrac{1}{2}x^2+\tfrac{1}{3}x^3-\tfrac{1}{4}x^4+, \&c.$$

Now we found that in the system whose base is a,

$$\log(1+x)=\frac{1}{A}\{x-\tfrac{1}{2}x^2+\tfrac{1}{3}x^3-\tfrac{1}{4}x^4+, \&c.\}$$

By comparing these two expressions for $\log(1+x)$, it appears that in the system whose base is e, the constant quantity A, which is

$$e-1-\tfrac{1}{2}(e-1)^2+\tfrac{1}{3}(e-1)^3-\tfrac{1}{4}(e-1)^4+, \&c.$$

is equal to unity. Logarithms computed according to this system are the same as those first given to the world by Napier, the celebrated inventor of logarithms, who was, however, led to them by a very different path from that here followed. It so happens that the same logarithms express hyperbolic areas, and hence they were called *hyperbolic* logarithms, a distinction quite improper, because hyperbolic areas may be expressed by logarithms of any system. Accordingly, it is now common to denominate them, in honour of the inventor, *Napierian* logarithms. In speaking of these, then, it must be understood that their base is $e=2{\cdot}718281828459$, &c.; and remembering that the letter l prefixed to any expression of a function means *Napier's logarithm* of that function (art. 19).

$$\mathrm{l.}(1+x)=x-\tfrac{1}{2}x^2+\tfrac{1}{3}x^3-,\tfrac{1}{4}x^4+, \&c.$$

and since $A=$ Nap. $\log a$ (see last article), therefore in the system whose base is a,

$$\log(1+x)=\frac{1}{\mathrm{l.}a}\{x-\tfrac{1}{2}x^2+\tfrac{1}{3}x^3-\tfrac{1}{4}x^4+, \&c.\}$$

The constant multiplier $\frac{1}{1.\,a}$, called the *modulus* of the system, is, for Briggs's logarithms,

$\frac{1}{1.(10)} = \cdot 4342944819033$ —, and its reciprocal,

$1.(10) = 2\cdot 302585092994$.

37. Let the function be $fx = u = \sin x$, then

$$\frac{du}{dx} = +\cos x, \frac{d^2u}{dx^2} = -\sin x, \frac{d^3u}{dx^3} = -\cos x,$$

$$\frac{d^4u}{dx^4} = +\sin x, \frac{d^5u}{dx^5} = +\cos x, \&c.$$

These values of the differential co-efficients being substituted in the theorem, it gives $f(x+h) = \sin(x+h)$

$$= \sin x + \cos x\frac{h}{1} - \sin x\frac{h^2}{1.2} - \cos x\frac{h^3}{1.2.3} + \sin x\frac{h^4}{1.2.3.4} +, \&c.$$

$$= \begin{cases} \sin x\left(1 - \frac{h^2}{2} + \frac{h^4}{2.3.4} - \frac{h^6}{2.3.4.5.6} +, \&c.\right) \\ +\cos x\left(h - \frac{h^3}{2.3} + \frac{h^5}{2.3.4.5} - \frac{h^7}{2.3.4.5.6.7} +, \&c.\right) \end{cases}$$

Let the function be $fx = u = \cos x$, then

$$\frac{du}{dx} = -\sin x, \frac{d^2u}{dx^2} = -\cos x, \frac{d^3u}{dx^3} = \sin x,$$

$$\frac{d^4u}{du^4} = \cos x, \frac{d^5u}{dx^5} = -\sin x, \&c.$$

and by substituting in the formula $f(x+h) = \cos(x+h)$

$$= \cos x - \sin x\frac{h}{1} - \cos x\frac{h^2}{2} + \sin x\frac{h^3}{2.3} + \cos x\frac{h^4}{2.3.4} -, \&c.$$

$$= \begin{cases} \cos x\left(1 - \frac{h^2}{2} + \frac{h^4}{2.3.4} - \frac{h^6}{2.3.4.5.6} +, \&c.\right) \\ -\sin x\left(h - \frac{h^3}{2.3} + \frac{h^5}{2.3.4.5} - \frac{h^7}{2.3.4.5.6.7} +, \&c.\right) \end{cases}$$

Put $P = 1 - \frac{h^2}{2} + \frac{h^4}{2.3.4} - \frac{h^6}{2.3.4.5.6} +, \&c.$

$Q = h - \frac{h^3}{2\cdot 3} + \frac{h^5}{2.3.4.5} - \frac{h^7}{2.3.4.5.6.7} +, \&c.$

Then $\sin(x+h) = P\sin x + Q\cos x$,

$\cos(x+h) = P\cos x - Q\sin x$.

Hence, by eliminating Q and P in succession,

$\sin(x+h)\sin x + \cos(x+h)\cos x = P$,

$\sin(x+h)\cos x - \cos(x+h)\sin x = Q$.

Therefore (ALGEBRA, 239), $\cos h = P$, $\sin h = Q$; and exchanging h for x,

$$\cos x = 1 - \frac{x^2}{2} + \frac{x^4}{2.3.4} - \frac{x^6}{2.3.4.5.6} +, \&c.$$

$$\sin x = x - \frac{x^3}{2.3} + \frac{x^5}{2.3.4.5} - \frac{x^7}{2.3.4.5.6.7} +, \&c.$$

The same results might have been obtained easier by making $x = 0$ in the series for $\sin(x+h)$ and $\cos.(x+h)$.

38. Let the function be the arc whose tangent is x, that is, $u = \tan^{-1} x$;

then $du = \frac{dx}{1+x^2} = dx\cos^2 u$ (art. 23),

and $\frac{du}{dx} = \cos u \cos u$,

The succeeding differential co-efficients will be found by formulæ (1) and (2) of article 26.

By (1) $\frac{d^2u}{dx^2} = -\sin 2u\cos^2 u$,

By (2) $\frac{d^3u}{dx^3} = -2\cos 3u\cos^3 u$,

By (1) $\frac{d^4u}{dx^4} = 2.3\sin 4u\cos^4 u$,

By (2) $\frac{d^5u}{dx^5} = 2.3.4\cos 5u\cos^5 u$,

By (1) $\frac{d^6u}{dx^6} = 2.3.4.5\sin 6u\cos^6 u$,

By (2) $\frac{d^7u}{dx^7} = -2.3.4.5.6\cos 7u\cos^7 u$, &c.

Hence, if we put $\tan u = x$, and $\tan u' = x+h$, we deduce from Taylor's theorem this very general and remarkable formula:

$$u' = u + \cos u\cos u\frac{h}{1} - \sin 2u\cos^2 u\frac{h^2}{2} - \cos 3u\cos^3 u\frac{h^3}{3}$$

$$+ \sin 4u\cos^4 u\frac{h^4}{4} + \cos 5u\cos^5 u\frac{h^5}{5}$$

$$- \sin 6u\cos^6 u\frac{h^6}{6} -, \&c.$$

If the arc u be supposed $= 0$, then $\sin u$, $\sin 2u$, &c. are each 0, and the powers of $\cos u$ each $= 1$, and the formula becomes

$$u = \tan u - \frac{1}{3}\tan^3 u + \frac{1}{5}\tan^5 u - \frac{1}{7}\tan^7 u +, \&c.$$

a formula due to James Gregory. We have found this series in a very different way (ALGEBRA, art. 270), and have there applied it to the determination of the ratio of the diameter to the circumference. It will be therefore sufficient to state the result here. Let π denote half the circumference of a circle, of which the rad. $= 1$, then

$\pi = 3\cdot 141592653590$—.

Maclaurin's Theorem.

39. There is a general formula nearly related to that of Taylor, and indeed an easy deduction from it, commonly called *Maclaurin's Theorem.* It is given at page 610 of the second volume of his fluxions (printed in 1742); but it is proper to say, that the same formula, in substance, was given in 1717 by Stirling, in his *Lineæ Tertii Ordines Neutonianæ*, p. 32.

We have found that $f(x) = u$ being any function of a variable x,

$$f(x+h) = u + \frac{du}{dx}h + \frac{d^2u}{dx^2}\frac{h^2}{2} + \frac{d^3u}{dx^3}\frac{h^3}{2.3} + \frac{d^4u}{dx^4}\frac{h^4}{2.3.4} +, \&c.$$

Suppose now that $x = 0$, and that by making this assumption

$f(x) = u$ becomes U,

also that $\frac{du}{dx}$ becomes U',

$\frac{d^2u}{dx^2}$ .... U'',

$\frac{d^3u}{dx^3}$ .... U''',

&c.

Then Taylor's theorem becomes

$$f(h) = U + U'h + U''\frac{h^2}{1.2} + U'''\frac{h^3}{1.2.3} +, \&c.$$

or, changing h into x,

$$f(x) = U + U'x + U''\frac{x^2}{1.2} + U'''\frac{x^3}{1.2.3} +, \&c.$$

From this it appears, that provided u be such a function of x as admits of being expanded into a series of the form

$$u = A + Bx + Cx^2 + Dx^3 +, \&c.$$

where A, B, C, D, &c. are constant quantities, then, U being the value of u when $x = 0$, and U', U'', U''', &c. be-

ing the values of the differential co-efficients $\frac{du}{dx}, \frac{d^2u}{dx^2}, \frac{d^3u}{dx^3}$, &c. found on that hypothesis, we have

$$A = U, B = U', C = U'', D = U''', \&c.$$

and consequently,

$$u = U + U'x + U''\frac{x^2}{2} + U'''\frac{x^3}{2 . 3} +, \&c.$$

This is Maclaurin's theorem, of which we shall now give some applications.

40. Let $u = (a + x)^n$. The expression of this expression has the requisite form; then $\frac{du}{dx} = n(a + x)^{n-1}$,

$$\frac{d^2u}{dx^2} = n(n-1)(a+x)^{n-2},$$

$$\frac{d^3u}{dx^3} = n(n-1)(n-2)(a+x)^{n-3}, \&c.$$

The supposition that $x = 0$ makes

$$u = a^n = U, \frac{du}{dx} = na^{n-1} = U', \frac{d^2x}{dx^2} = n(n-1)a^{n-2} = U'',$$

$$\frac{d^3u}{dx^3} = n(n-1)(n-2)a^{n-3} = U''', \&c.$$

The proper substitutions being made in the general theorem, we have

$$(a + x)^n = a^n + na^{n-1}x + \frac{n(n-1)}{1 . 2}a^{n-2}x^2 + \frac{n(n-1)(n-2)}{1 . 2 . 3}a^{n-3}x^3 +, \&c.$$

41. Let $u = a^x$. This function is also of the kind that admits of expansion by the theorem; the differential co-efficients are (art. 19), putting $A = l. a$,

$$\frac{du}{dx} = Aa^x, \frac{d^2u}{dx^2} = A^2a^x, \frac{d^3u}{dx^3} = A^3a^x, \&c.$$

The supposition that $x = 0$ gives $u = 1$, and

$$\frac{du}{dx} = A, \frac{d^2u}{dx^2} = A^2, \frac{d^3u}{dx^3} = A^3, \&c.$$

Hence $a^x = 1 + Ax + \frac{A^2x^2}{1 . 2} + \frac{A^3x^3}{1 . 2 . 3} +, \&c.$

as was found in art. 35.

42. The formula $u = \log x$ does not admit of being expanded into a series of the prescribed form, for in this case $\frac{du}{dx} = \frac{1}{Ax}$; the supposition that $x = 0$ makes u and $\frac{du}{dx}$, as well as all the following differential co-efficients, infinite. The function $u = \log(n + x)$, however, admits of the application of the formula. In this case (art. 20),

$$\frac{du}{dx} = \frac{1}{A(n + x)}, \frac{d^2u}{dx^2} = \frac{-1}{A(n+x)^2}, \frac{d^3u}{dx^3} = \frac{1 . 2}{A(n+x)^3}, \&c.$$

The assumption that $x = 0$ makes $u = \log n = U$, and

$$\frac{du}{dx} = \frac{1}{An} = U', \frac{d^2u}{dx^2} = -\frac{1}{An^2} = U'', \frac{d^3u}{dx^3} = \frac{1 . 2}{An^3} = U''', \&c.$$

We have now, by the general formula,

$$\log(n + x) = \log n + \frac{1}{A}\left\{\frac{x}{n} - \frac{x^2}{2n} + \frac{x^3}{3n} -, \&c.\right\}.$$

By making $n = 1$, and therefore $\log n = 0$, we have the expression for $\log(1 + x)$, as already found.

43. The theorem may be applied to the functions $u = \sin x$, and $u = \cos x$, without the least difficulty. For the first we have

$$U = 0, \quad U' = 1, \quad U'' = 0, \quad U''' = -1, \&c.$$

and $\sin x = x - \frac{x^3}{1 . 2 . 3} + \frac{x^5}{1 . 2 . 3 . 4 . 5} +, \&c.$;

for the second function

$$U = 1, \quad U' = 0, \quad U'' = -1, \quad U''' = 0, \&c.$$

$$\cos x = 1 - \frac{x^2}{1 . 2} + \frac{x^4}{1 . 2 . 3 . 4} - \frac{x^6}{1 . 2 . 3 . 4 . 5 . 6} +, \&c.$$

44. Let u denote the arc whose sine is x; that is, let $u = \sin^{-1} x$. In this case (23),

$$\frac{du}{dx} = (1 - x^2)^{-\frac{1}{2}},$$

$$\frac{d^2u}{dx^2} = x(1 - x^2)^{-\frac{3}{2}},$$

$$\frac{d^3u}{dx^3} = (1 - x^2)^{-\frac{3}{2}} + 3x^2(1 - x^2)^{-\frac{5}{2}},$$

$$\frac{d^4u}{dx^4} = 3 . 3x(1 - x^2)^{-\frac{5}{2}} + 3 . 5x^3(1 - x^2)^{-\frac{7}{2}},$$

&c.

Making $x = 0$ we get $U = 0$, $U' = 1$, $U'' = 0$, $U''' = 1$, $U^{IV} = 0$; and, by continuing the process of differentiation, $U^{V} = 3 . 3$, &c. therefore

$$u = x + \frac{x^3}{1 . 2 . 3} + \frac{3 . 3x^5}{1.2.3.4.5} + \frac{3^2 . 5^2x^7}{1.2.3.4.5.6.7} +, \&c.$$

Cases in which Taylor's Theorem fails.

45. We have seen that Taylor's theorem, viz. $u = f(x)$ being any function of a variable x,

$$f(x+h) = u + \frac{du}{dx}\frac{h}{1} + \frac{d^2u}{dx^2}\frac{h^2}{1 . 2} + \frac{d^3u}{dx^3}\frac{h^3}{1.2.3} +, \&c.$$

will always hold true, provided that the variable x be regarded as indeterminate. If however particular values be given to x, there are cases in which the development is of no use, because in these cases it is not applicable to the function.

For example, let $u = b + (x - a)^{\frac{1}{2}}$; in this case,

$$\frac{du}{dx} = \frac{1}{2(x - a)^{\frac{1}{2}}}, \frac{d^2u}{dx^2} = -\frac{1}{4(x - a)^{\frac{3}{2}}}, \&c.$$

and by the theorem,

$$f(x + h) = b + (x - a + h)^{\frac{1}{2}} = b + (x - a)^{\frac{1}{2}} + \frac{1}{2(x - a)^{\frac{1}{2}}}h - \frac{1}{8(x - a)^{\frac{3}{2}}}h^2 +, \&c.$$

Now if we give to x any particular value greater than a, the development is perfectly significant, and expresses truly the value of $b + (x - a + h)^{\frac{1}{2}}$. If however we give to x the particular value a, then $x - a = 0$, and the development becomes $b + 0 + \frac{h}{2(0)^{\frac{1}{2}}} - \frac{h^2}{8(0)^{\frac{3}{2}}} +, \&c.$ from which no conclusion whatever can be drawn, because all the terms having *zero* in the denominator are infinite. If in the expression $b + (x - a + h)^{\frac{1}{2}}$ we make $x = a$, it becomes $b + h^{\frac{1}{2}}$. This expression has two values, viz. $b + \sqrt{h}$, $b - \sqrt{h}$. The development given by the theorem contains, however, only positive integer powers of h; therefore it can have only a single value; and hence it is impossible that it should express the function in the particular case of $x = a$. In such cases the theorem has been said to *fail*; this however happens not from any imperfection in the theorem, but merely because it is unsuitable to the purpose to which it has been applied; and this want of applicability is indicated by the co-efficients of the powers of h failing to express any thing definite.

46. Again, let the function be $u = \frac{b}{(x - a)^2}$; then

Direct Method.

$$\frac{du}{dx} = -\frac{2b}{(x-a)^3}, \frac{d^2u}{dx^2} = \frac{6b}{(x-a)^4}, \text{ \&c.}$$

In this case

$$f(x+h) = \frac{b}{(x-a+h)^2} = \frac{b}{(x-a)^2} - \frac{2b}{(x-a)^3}h + \frac{3b}{(x-a)^4}h^2 -, \text{ \&c.}$$

Here x may have any particular value greater or less than a, and the development will be perfectly significant; if, however, x be equal to a, it becomes

$$\frac{b}{(o)^2} - \frac{2\,b}{(o)^3}h + \frac{3\,b}{(o)^4}h^2 -, \text{ \&c.};$$

an expression that has no meaning, because each of the co-efficients of h is infinite.

If we make $x = a$ in $\frac{b}{(x-a+h)^2}$, the function to be expanded, it becomes $\frac{b}{h^2} = bh^{-2}$, an expression in which the exponent of h is negative; therefore this case cannot be included in a formula which contains only positive integers of h, and hence the apparent failure of the theorem.

47. That a general formula should not express all particular cases, was at one time regarded as a kind of paradox in analysis. Lagrange first cleared up this point, and showed, that when by giving particular values to x, the new state of the function contains terms of the form Ph^{-n}, or $Qh^{\frac{m}{n}}$, that is, negative or fractional powers of h, then, from the very nature of the calculus, all the co-efficients in the general development after a certain term will become infinite. On the other hand, when a particular value of x renders the co-efficients infinite, we may conclude that the development in that case ought to contain fractional or negative powers of h. In such particular cases as appear not to admit of expansion by Taylor's theorem, other methods deducible from the calculus are applicable; in general, the ordinary algebraic methods are sufficient.

Differentiation of Equations of two Variables.

48. We have as yet differentiated only equations in which the variables were separated, such as this, $y = a + b\,x + cx^2$, where y is an explicit function of x. But the equations which chiefly occur in analytical inquiries contain for the most part the two variables combined or mixed together; as in this equation,

$$y^2 - 2\,mxy + x^2 - a^2 = 0.$$

If we suppose the equation resolved, so that y is expressed in terms of x only, which gives

$$y = mx \pm \sqrt{a^2 + (m^2-1)\,x^2},$$

the differentials may be found by the rules already explained. In general, however, the variables cannot be so separated, and therefore it is necessary that we be able to determine the differential co-efficients of a function by other means.

49. An equation formed in any way from two independent variable quantities may be represented by the general symbol

$$f(x, y) = 0.$$

The variable y must be expressible in some way by x; therefore we may represent its value, however found, by the equation $y = X$, where X denotes an expression made up of terms containing only x and constant quantities. When this value of y is substituted in the equation, it becomes

$$f(x, X) = 0.$$

This is an identical equation, involving x only, which must hold true whatever value be given to x. Let the expression $f(x, X) = f(x, y)$ be denoted briefly by u. Suppose now x to change its value and become $x + h$; by Taylor's theorem, its new values will be

$$u' = u + \frac{du}{dx}h + \frac{d^2u}{dx^2}h^2 + \frac{d^3u}{dx^3}h^3 +, \text{ \&c.}$$

The equation $f(x, y) = u = 0$ must hold true whatever value be given to x; therefore we must have $u' = 0$, and this requires that the co-efficients of the different powers of the indeterminate quantity h be separately $= 0$ (art. 18), so that from the equation $u = f(x, y) = 0$ there may be derived a series of equations,

$$\frac{du}{dx} = 0, \frac{d^2u}{dx^2} = 0, \frac{d^3u}{dx^3} = 0, \text{ \&c.}$$

which must all hold true at the same time as the original equation.

50. Let us take for example the equation

$$y^2 + x^2 = a^2, \text{ or } y^2 + x^2 - a^2 = 0 \ldots\ldots\ldots(1.)$$

in which a is a constant quantity; in this case,

$$u = y^2 + x^2 - a^2;$$

hence we have by differentiation

$$\frac{du}{dx} = 2\,y\frac{dy}{dx} + 2\,x = 0,$$

$$\text{and } \frac{dy}{dx} = -\frac{x}{y} \ldots\ldots\ldots\ldots\ldots\ldots(2.).$$

To determine the differential co-efficient of the second order, put $\frac{dy}{dx} = p$, and we have

$$\frac{du}{dx} = 2\,yp + 2\,x;$$

as p is a function of x and y, and y is a function of x, therefore p is a function of x. Taking now the differentials, and dividing by dx, the result is

$$\frac{d^2u}{dx^2} = 2\left(y\frac{dp}{dx} + p\frac{dy}{dx} + 1\right) = 0;$$

hence, because $p = \frac{dy}{dx}$, and $\frac{dp}{dx} = \frac{d^2y}{dx^2}$,

$$\frac{d^2u}{dx^2} = 2\left(y\frac{d^2y}{dx^2} + \frac{dy^2}{dx^2} + 1\right) = 0 \ldots\ldots\ldots\ldots(3.)$$

From this equation we get

$$\frac{d^2y}{dx^2} = -\frac{1}{y}\left(\frac{dy^2}{dx^2} + 1\right),$$

$$\text{or, since } \frac{dy}{dx} = -\frac{x}{y},$$

$$\frac{d^2y}{dx^2} = -\frac{x^2}{y^3} - \frac{1}{y} \ldots\ldots\ldots\ldots(4.)$$

To find the differential co-efficient of the third order, we put $\frac{d^2y}{dx^2} = \frac{dp}{dx} = q$; and substituting p for $\frac{dy}{dx}$ in equation (3), it becomes

$$\frac{d^2u}{dx^2} = 2\,(yq + p^2 + 1) = 0;$$

observing that p and q are functions of x and y, and consequently of x, we may find by differentiation an expression which will involve, besides x and y, these quantities,

$$\frac{dq}{dx}, \frac{dp}{dx} = \frac{d^2y}{dx^2}, q = \frac{d^2y}{dx^2}, p = \frac{dy}{dx};$$

and from this equation $\frac{dq}{dx} = \frac{d^3y}{dx^3}$ may be determined, observing that $\frac{d^2y}{dx^2}$ and $\frac{dy}{dx}$ are expressed by x and y in equations (4) and (2).

51. The preceding analysis gives the following rule for

determining the differential co-efficients of y, a function of x, when the relation between x and y is expressed by an equation.

Take the differentials of the terms of the equation, considering y as a function of x, and dividing by dx, the result will be an equation which gives the value of $\frac{dy}{dx}$. Again, take the differentials of the terms of this equation, considering y and $\frac{dy}{dx}$ as functions of x, and the result will be an equation involving $\frac{d^2y}{dx^2}$ and $\frac{dy}{dx}$, which, combined with the former, serves to determine $\frac{d^2y}{dx^2}$. A third equation may be found from this, by taking the differentials, and considering y, $\frac{dy}{dx}$, and $\frac{d^2y}{dx^2}$, as functions of x; and this, combined with the other two, gives $\frac{d^3y}{dx^3}$, and so on to any number of equations.

Let y be such a function of x that

$$y^2 - 2\,mxy + x^2 - a^2 = 0 \quad \ldots\ldots\ldots\ldots (1.)$$

It is proposed to determine its differential co-efficients.

By a first differentiation

$$(y - mx)\,dy - (my - x)\,dx = 0,$$

$$\text{and } \frac{dy}{dx} = \frac{my - x}{y - mx} \quad \ldots\ldots\ldots\ldots (2.)$$

Again, by differentiating,

$$\frac{d^2y}{dx^2} = \frac{(1 - m^2)x}{(y - mx)^2} \cdot \frac{dy}{dx} - \frac{(1 - m^2)y}{(y - mx)^2} \ldots\ldots (3.)$$

and, substituting for $\frac{dy}{dx}$ its value,

$$\frac{d^2y}{dx^2} = -(1 - m^2)\frac{y^2 - 2\,mxy + x^2}{(y - mx)^3} = \frac{-(1 - m^2)a^2}{(y - mx)^3} (4.)$$

If we take the differentials of both sides of equation (3), and consider $\frac{dy}{dx}$, $\frac{d^2y}{dx^2}$, as functions of x, we shall obtain

$$\frac{d^3y}{dx^3} = \mathrm{P}\frac{d^2y}{dx^2} + \mathrm{Q}\frac{dy}{dx} + \mathrm{R} \ldots\ldots\ldots\ldots (5.)$$

Here P, Q, R, denote expressions composed of y and x. By substituting for $\frac{d^2y}{dx^2}$ and $\frac{dy}{dx}$ their values as given by equations (4) and (2), there will be obtained the value of $\frac{d^3y}{dx^3}$, in terms of x and y.

52. The equations which may be deduced by differentiation from a proposed equation are called *fluxional* or *differential* equations, and the equation from which they have been deduced is called the *primitive* equation. The equation which gives the value of $\frac{dy}{dx}$ is said to be of the *first order*, and that which involves $\frac{d^2y}{dx^2}$ is of the *second order*, and so on for the higher orders.

Thus, the primitive equation being

$$y^2 - 2mxy + x^2 - a^2 = 0,$$

we have found, for the differential equation of the first order,

$$\frac{dy}{dx} - \frac{my - x}{y - mx} = 0;$$

and that of the second order,

$$\frac{d^2y}{dx^2} - \frac{(1 - m^2)x}{(y - mx)^2} \cdot \frac{dy}{dx} + \frac{(1 - m^2)y}{(y - mx)^2} = 0,$$

equivalent to $\frac{d^2y}{dx^2} + (1 - m^2)\frac{y^2 - 2mxy + x^2}{(y - mx)^3} = 0.$

53. Differential equations of all orders hold true simultaneously with the primitive from which they have been derived, therefore any combination of them will also hold true; and whatever number of values the function y has (in the preceding example it has two), the differential co-efficients into which y enters will have the same number.

It has appeared (art 15) that in functions of a certain form the constants they contain vanish from their differentials. A like remark applies to differential equations. Thus, if $y^2 = ax + b$ be a primitive equation, in which a and b are constants, the differential equation is $2ydy = adx$; and this belongs to every particular equation which can be formed from the primitive, by giving all possible values to b. The constant a may also be made to disappear by putting the equation under this form,

$$\frac{y^2}{x} = a + \frac{b}{x};$$

for this by differentiation gives

$$\frac{2xydy - y^2dx}{x^2} = \frac{-bdx}{x^2},$$

$$\text{and } 2xydy - (y^2 - b)\,dx = 0;\ \text{or } \frac{dy}{dx} = \frac{y^2 - b}{2xy}.$$

This equation expresses a relation which subsists between the quantities x, y, $\frac{dy}{dx}$, independently of any particular value of the constant a.

The very same equation will be obtained by eliminating, by the ordinary process (ALGEBRA, sect. 7), a from the two equations

$$y^2 = ax + b,\ 2ydy = adx.$$

If the constant quantity which is eliminated is not of the first degree in the proposed equation, the result will contain powers of the co-efficient $\frac{dy}{dx}$ higher than the first. For example, let the equation be

$$y^2 - 2ay + x^2 = a^2;$$

then, by differentiating,

$$ydy - ady + xdx = 0,$$

hence $a = \frac{ydy + xdx}{dy}$.

This value of a being substituted in the proposed equation, we obtain, after due reduction,

$$(x^2 - 2y^2)\frac{dy^2}{dx^2} - 4xy\frac{dy}{dx} - x^2 = 0;$$

an equation that expresses a relation between x, y, $\frac{dy}{dx}$, which is independent of any particular value of a.

By resolving the equation in respect of a, we find

$$a = -y \pm \sqrt{2y^2 + x^2};$$

and hence, the constant a forming a term by itself, it disappears by differentiation, and we have

$$dy \pm \frac{2ydy + xdx}{\sqrt{2y^2 + x^2}} = 0,$$

an equation which, being freed from the radical sign, will be identical with the former.

54. Any number of constants whatever may be made to disappear by repeating the process of differentiation as often as there are quantities to be eliminated; for example, let the equation be $y^2 = m\,(a^2 - x^2)$; by a first differentiation $y\,\frac{dy}{dx} = -mx$; taking the differentials a se-

cond time, we get $y\frac{d^2y}{dx^2}+\frac{dy^2}{dx^2}=-m$. This value of $-m$ being substituted in the former equation, it becomes

$$y\frac{dy}{dx}-x\frac{dy^2}{dx^2}-xy\frac{d^2y}{dx^2}=0,$$

a result which is independent of both a and m.

Of Vanishing Fractions.

55. When the numerator and denominator of a fraction are such functions that, by giving a particular value to their variable, they both become $=0$ at the same time, the fraction is then called a *vanishing* fraction. The fraction $\frac{x^2-a^2}{x-a}$ is of this kind; for when $x=a$, the numerator and denominator both vanish, and the fraction takes the form $\frac{0}{0}$, from which we can draw no conclusion as to its true value, although it be evident that the fraction has then a determinate value; for

$$\frac{x^2-a^2}{x-a}=\frac{(x+a)(x-a)}{x-a}=x+a;$$

and when $x=a$, its true value is as $a+a=2a$.

It appears that the above fraction has taken the peculiar form $\frac{0}{0}$ when $x=a$, from the circumstance of its having the factor $x-a$ in the numerator and denominator. The same is true of this other fraction,

$$\frac{x^3-x^2a-xa^2+a^3}{ax-a^2},$$

which takes form $\frac{0}{0}$ when $x=a$. The numerator and denominator have a common divisor, $x-a$; when freed from this, it becomes $\frac{x^2-a^2}{a}$; when $x=a$, this fraction becomes $\frac{0}{a}$, which is truly $=0$. Again, this fraction $\frac{ax-a^2}{x^2-2ax+a^2}$, which has the same property when $x=a$, by reason of the common factor $x-a$, when freed from the factor is $\frac{a}{x-a}$. Thus when $x=a$ becomes $\frac{a}{0}$, that is, the value is infinite. In these cases the common factor is obvious; but it is not so always. Take this as an example, $\frac{1-\sin x+\cos x}{\sin x+\cos x-1}$; when x is a quadrant, or $=\frac{1}{2}\pi$, this fraction becomes $\frac{0}{0}$. For its true value in this case, see ex. 4 of art. 57.

56. When the terms of the fraction are algebraic functions, their greatest common measure may be found by an elementary operation in ALGEBRA (art. 20), and the fraction disengaged from it by division. A more simple and general solution may, however, be obtained from the differential calculus.

Let $\frac{P}{Q}$ denote a fraction, the terms of which are functions of x that vanish when $x=a$, some given quantity. Suppose now that x becomes $x+h$, then, by Taylor's theorem, the fraction will become

$$\frac{P+\frac{dP}{dx}h+\frac{d^2P}{dx^2}\frac{h^2}{1.2}+\frac{d^3P}{dx^3}\frac{h^3}{1.2.3}+,\&c.}{Q+\frac{dQ}{dx}h+\frac{d^2Q}{dx^2}\frac{h^2}{1.2}+\frac{d^3Q}{dx^3}\frac{h^3}{1.2.3}+,\&c.}.$$

By hypothesis, when $x=a$, then P and Q both vanish; therefore, leaving them out of the expression, and putting P', P'', P''', &c. to denote the differential co-efficients of P in the numerator, and Q', Q'', Q''', &c. those of Q in the denominator, and dividing the terms by h, the fraction will be expressed by

$$\frac{P'+\frac{1}{2}P''h+\frac{1}{6}P'''h^2+,\&c.}{Q'+\frac{1}{2}Qh+\frac{1}{6}Q'''h^2+,\&c.}.$$

When $h=0$, this expression becomes $\frac{P'}{Q'}$; and when a is put in this fraction instead of x, the result will be the true value of $\frac{P}{Q}$; for it is manifestly the same thing to suppose, first, that x becomes $x+h$, and then that $x=a$ and $h=0$, as to suppose at once that $x=a$.

If it happen that one of the two quantities, P', Q', becomes $=0$ when a is substituted instead of x, then the fraction $\frac{P}{Q}$ will be $=0$, or infinite, according as the vanishing quantity is the numerator or denominator; if both become $=0$ at once, then, leaving them out, the expression becomes, by reduction,

$$\frac{P''+\frac{1}{3}P'''h+,\&c.}{Q''+\frac{1}{3}Q'''h+,\&c.};$$

and making $h=0$, it become $\frac{P''}{Q''}$, which, putting a instead of x, will be the value of the fraction $\frac{P}{Q}$, and so on.

57. Hence we have this rule: To find the fraction $\frac{P}{Q}$ in the particular case of $x=a$, supposing that P and Q are both reduced to 0 by this supposition. Divide the differential co-efficient of the numerator by that of the denominator; let the result be $\frac{P'}{Q'}$, in which make $x=a$; then, if this expression does not become $\frac{0}{0}$, it is the value sought; but if it takes the form $\frac{0}{0}$, treat the fraction $\frac{P'}{Q'}$ in all respects like the original fraction, and deduce from it a new fraction $\frac{P''}{Q''}$, and proceed in this way until an expression be found which does not become $\frac{0}{0}$ when a is put for x; and the first expression that is found having this property is the value sought.

Ex. 1. The sum of the geometrical series

$$1+x+x^2+x^3\ldots+x^{n-1} \text{ to } n \text{ terms}$$

is $\frac{x^n-1}{x-1}$. Find its value when $x=1$.

In this case, $P=x^n-1$, $Q=x-1$; hence we deduce $\frac{dP}{dx}=nx^{n-1}=P'$; $\frac{dQ}{dx}=1=Q$, $\frac{P'}{Q'}=nx^{n-1}$;

when $x=1$, the fraction $\frac{P'}{Q'}=n$, the value of the sum of the series, as is manifest.

Ex. 2. Let the fraction be $\frac{ax^2+ac^2-2acx}{bx^2-2bcx+bc^2}=\frac{P}{Q}$, which becomes $\frac{0}{0}$ when $x=c$, to find its value. In this case $\frac{dP}{dx}=2ax-2ac=P'$; $\frac{dQ}{dx}=2bx-2bc=Q'$;

$$\frac{P'}{Q'} = \frac{2ax - 2ac}{2bx - 2bc} = \frac{ax - ac}{bx - bc}.$$

Making $x = c$, this fraction becomes $\frac{0}{0}$, therefore, proceeding as before,

$$\frac{d^2P}{dx^2} = 2a = P'', \ \frac{d^2Q}{dx^2} = 2b = Q'', \ \frac{P''}{Q''} = \frac{a}{b};$$

hence it appears that when $x = c$, the value of the fraction is $\frac{a}{b}$.

Ex. 3. The fraction $\frac{a^x - b^x}{x}$ becomes $\frac{0}{0}$ when $x = 0$. Find its value then. In this case,

$$\frac{dP}{dx} = \text{l.}\ (a)\ a^x - \text{l.}\ (b)\ b^x = P'; \ \frac{dQ}{dx} = 1 = Q'.$$

When $x = 0$, $\frac{P'}{Q'}$ becomes $\text{l.}\,(a) - \text{l.}\,(b) = \text{l.}\,\frac{a}{b}$, the value required.

Ex. 4. Let the fraction be $\frac{1 - \sin x + \cos x}{\sin x + \cos x - 1}$, which becomes $\frac{0}{0}$ when $x = \frac{1}{2}\pi$. Here

$$\frac{dP}{dx} = -\cos x - \sin x = P'; \ \frac{dQ}{dx} = \cos x - \sin x = Q';$$

$$\frac{P'}{Q'} = \frac{-\cos x - \sin x}{\cos x - \sin x}.$$

When $x = \frac{1}{2}\pi$, a quadrant, then $\cos x = 0$, and $\sin x = 1$; the value of the proposed fraction is therefore $\frac{-1}{-1} = 1$.

Ex. 5. Let the fraction be $\frac{a^{a-n} - x^{x-n}}{a - x}$; to find its value when $x = a$. In this case $P = a^{a-n} - x^{x-n}$, $Q = a - x$.

$$P' = \frac{dP}{dx} = -x^{x-n}\left\{\text{l.}\,x + \frac{x-n}{x}\right\};$$

$$Q' = \frac{dQ}{dx} = -1,$$

$$\frac{P'}{Q'} = x^{x-n}\left\{\text{l.}\,x + \frac{x-n}{x}\right\}:$$

making $x = a$, we have $a^{a-n}\left\{\text{l.}\,a + \frac{a-n}{a}\right\}$ for the value required.

58. The rule of last article will not apply when Taylor's theorem fails to give the developments of the functions P, Q, in the case when $x = a$. When this happens, we may substitute $a + h$ instead of x in the fraction $\frac{P}{Q}$, and expand the numerator and denominator into ascending series, which proceed by the powers of h; we shall then have

$$\frac{Ah^{\alpha} + Bh^{\beta} +, \&c.}{A'h^{\alpha'} + B'h^{\beta'} +, \&c.}$$

instead of the proposed fraction. If in this result we suppose $h = 0$, we shall have the value of the fraction $\frac{P}{Q}$ when $x = a$. Now there are here three cases; viz. $\alpha > \alpha'$, $\alpha = \alpha'$, and $\alpha < \alpha'$. In the first case, we may write the expression thus:

$$\frac{Ah^{\alpha - \alpha'} + Bh^{\beta - \alpha} +, \&c.}{A' + B'h^{\beta - \alpha'} +, \&c.};$$

Under this form, it is manifest that as long as α is greater than α', the supposition of $h = 0$ will make the fraction equal to nothing, and that it will become $\frac{A}{A'}$ when $\alpha = \alpha'$; but when $\alpha < \alpha'$, we write the expression thus:

$$\frac{A + Bh^{\beta - \alpha} +, \&c.}{A'h^{\alpha' - \alpha} + B'h^{\beta' - \alpha} +, \&c.};$$

and by the supposition of $h = 0$, this result becomes infinite. In all cases the true value depends on the first term alone of each series.

59. The following rule extends to all fractions which can occur under the indeterminate form $\frac{0}{0}$.

Take the first term of each of the series which express the development of the numerator and denominator when x = a + h; *reduce the resulting fraction to its most simple form, and then make* h = 0.

The fraction $\frac{(x^2 - a^2)^{\frac{5}{2}}}{(x - a)^{\frac{5}{2}}}$, whose value cannot be found by differentiation, when $x = a$ becomes by this method

$$\frac{(2ah + h^2)^{\frac{5}{2}}}{h^{\frac{5}{2}}} = (2a + h)^{\frac{5}{2}},$$

when x is changed into $x + h$; making now $h = 0$, we have its true value $(2a)^{\frac{5}{2}}$.

This last rule will sometimes be preferable to the former, by differentiation, even when that process is applicable. For example, four successive differentiations must be performed on the numerator and denominator of this fraction,

$$\frac{x^3 - 4ax^2 + 7a^2x - 2a^3 - 2a^2\sqrt{2ax - a^2}}{x^2 - 2ax - a^2 + 2a\sqrt{2ax - x^2}},$$

in order to find its true value when $x = a$; by writing $a + h$ instead of x, it becomes

$$\frac{2a^3 + 2a^2h - ah^2 + h^3 - 2a^2\sqrt{a^2 + 2ah}}{-2a^2 + h^2 + 2a\sqrt{a^2 - h^2}}$$

and reducing the radical quantities into series, we have

$$\sqrt{a^2 + 2ah} = a + h - \frac{h^2}{2a} + \frac{h^3}{2a^2} - \frac{5h^4}{8a^3} +, \&c.$$

$$\sqrt{a^2 - h^2} = a - \frac{h^2}{2a} - \frac{h^4}{8a^3} -, \&c.$$

By substituting these series in the fraction, and putting $h = 0$, we obtain $-5a$ for the value sought.

Of the greatest and least Values of a Function.

60. In supposing that a function changes its value, we may assume that the variable increases continually from 0 to infinity, either positively or negatively. To get distinct notions, it may be convenient to suppose that the variable increases or decreases by successive equal differences. The function however may not increase or decrease continually along with its variable. It may first increase to a certain magnitude, and afterwards decrease; or it may decrease and afterwards increase; or it may alternately increase and decrease several times. We may represent the variable x by the abscissa of a curve, and the function y by the corresponding ordinate. The curve, from

Direct Method.

its nature, may recede continually from its axis, like the parabola and hyperbola; or it may first recede from and afterwards approach to the axis, like the circle and ellipse; or it may be sinuous, alternately approaching and receding.

When a variable function, by a continual change in its magnitude, first increases and afterwards decreases, there will be one value of the function which will be greater than those which immediately preceded it, and also greater than those which immediately follow it. In this state the value of the function is the greatest possible, at least within certain limits on each side of that extreme value; and then it is said to be a *maximum*. On the other hand, if a function, by a continual change in its value, first decreases, until it be reduced to a certain magnitude, and afterwards increases, it is said to be a *minimum*, when it is just changing from the state of a decreasing to that of an increasing quantity.

A variable function may have several values, each of which will be a *maximum* or *minimum*, according to the definition. *The essential character of a maximum consists in its being greater than the values which preceded and which follow it; and that of a minimum in being less than the preceding and following values.* So that as many changes as there may be from increase to decrease, or the contrary, so many *maxima* and *minima* there will be.

61. Before proceeding farther, it will be convenient to establish this principle. In a series of the form

$$ph + qh^2 + rh^3 + sh^4 +, \&c.$$

in which h is indeterminate, and independent of p, q, r, &c. such a value may be given to h, that any term shall exceed the amount of all that follow it. For, putting the series under this form,

$$h\,(p + qh + rh^2 + sh^3 +, \&c.);$$

by supposing h to decrease, $qh + rh^2 + sh^3 +$, &c. may become less than any assignable quantity, and therefore less than p; consequently, $qh^2 + rh^3 + sh^4 +$, &c. may be less than ph, in any ratio of inequality. In the same way it will appear that $rh + sh^2 +$, &c. may be less than q, and $rh^3 + sh^4 +$, &c. less than qh^2, and so on. Hence it follows, that in the series $ph + qh^2 + rh^3 + sh^4 +$, &c. h may have such a value that the amount of all the terms beginning with any assigned term shall have the sign of that term, $+$ if it be $+$, and $-$ if it be $-$.

62. Let y denote any function which may become a *maximum* or *minimum* when its variable has attained some particular value; then, if $x - h$ and $x + h$ be substituted successively in the function instead of x, the two results must be both less than the maximum value, and both greater than the minimum value. Denoting now the value of the function which corresponds to $x - h$ by ${}_1y$, and the value which corresponds to $x + h$ by y_1, we have, by Taylor's theorem,

$${}_1y = y - \frac{dy}{dx}h + \frac{d^2y}{dx^2}\frac{h^2}{1.2} - \frac{d^3x}{dx^3}\frac{h^3}{1.2.3} +, \&c.$$

$$y_1 = y + \frac{dy}{dx}h + \frac{d^2y}{dx^2}\frac{h^2}{1.2} + \frac{d^3y}{dx^3}\frac{h^3}{1.2.3} +, \&c.$$

Now, it is impossible that ${}_1y$ and y_1 can at the same time be both less or both greater than y, if the co-efficient $\frac{dy}{dx}$ be not $= 0$; for if it have some value different from *zero*, then such a value may be given to h that $\frac{dy}{dx}h$ shall exceed in any given ratio of inequality all the terms which follow it, and one of the two series beginning with $\mp\frac{dy}{dx}h$ will be a positive quantity and the other negative; and if this were true, y would be of an intermediate magnitude between ${}_1y$ and y_1, which cannot be, when it is a *maximum* or *minimum*. Therefore, in order that y may be a *maximum* or *minimum*, we must have $\frac{dy}{dx} = 0$, and then, in the expressions

$${}_1y = y + \frac{d^2y}{dx^2}\frac{h^2}{1.2} - \frac{d^3y}{dx^3}\frac{h^3}{1.2.3} +, \&c.$$

$$y_1 = y + \frac{d^2y}{dx^2}\frac{h^2}{1.2} + \frac{d^3y}{dx^3}\frac{h^3}{1.2.3} +, \&c.$$

such a value may be given to h as shall make ${}_1y$ and y_1 both less than y in the case of a *maximum*, or both greater in that of a *minimum*.

It may, however, happen that the value of x which makes $\frac{d^2y}{dx^2} = 0$ shall also make $\frac{d^2y}{dx^2} = 0$, so that we have

$${}_1y = y - \frac{d^3y}{dx^3}\frac{h^3}{1.2.3} + \frac{d^4y}{dx^4}\frac{h^4}{1.2.3.4} -, \&c.$$

$$y_1 = y + \frac{d^3y}{dx^3}\frac{h^3}{1.2.3} + \frac{d^4y}{dx^4}\frac{h^4}{1.2.3.4} +, \&c.$$

Then the function cannot be a maximum or minimum, unless the same value of x make $\frac{d^3y}{dx^3} = 0$, and give a finite value for $\frac{d^4y}{dx^4}$

63. On the whole, we have this rule, to determine the maximum or minimum value of y, a function of x.

Make the differential co-efficient $\frac{dy}{dx} = 0$: *Find the value of* x, *and substitute it in* $\frac{d^2y}{dx^2}$; *and if the result be negative, the function is a* maximum; *but if it be positive, the function is a* minimum. *And if it be* $= 0$, *then put* $\frac{d^3y}{dx^3} = 0$, *and find* x, *and substitute it in* $\frac{d^4y}{dx^4}$, *and draw the same conclusions from the signs as before, and so on.*

The rule for determining a maximum or minimum of a function was first given correctly by Maclaurin, in his FLUXIONS, chap. ix.

64. We shall now apply the theory to the resolution of problems, of which there may be an endless variety, and many highly interesting.

Ex. 1. To determine whether the function $u = 2ax - x^2$ has a *maximum* or *minimum* value.

In this case the differential co-efficient $\frac{du}{dx} = 2\,(a - x)$, which being put $= 0$, we have $x = a$. The second differential co-efficient $\frac{d^2u}{dx^2} = -2$, a negative quantity, therefore the function has a maximum value (art. 63), viz. when $x = a$; and that value is $u = a^2$, as is indeed evident from the nature of the function.

Ex. 2. Let $u = x^2 + 3x + 2$; then $\frac{du}{dx} = 2x + 3$. This put $= 0$, gives $x = -\frac{3}{2}$. Again, $\frac{d^2u}{dx^2} = 2$, a positive quantity, therefore the function is a *minimum* when $x = -\frac{3}{2}$. In that case $u = -\frac{1}{4}$.

Ex. 3. Let $u = x^3 - 15x^2 + 56x - 60$. Here

$$\frac{du}{dx} = 3x^2 - 30x + 56,\ \frac{d^2u}{dx^2} = 6x - 30.$$

Direct Method.

The equation $\frac{du}{dx} = 3x^2 - 30x + 56 = 0$ being resolved, we find $x = \frac{15 \pm \sqrt{57}}{3}$. Making $x = \frac{15 \pm \sqrt{57}}{3}$, we find $\frac{d^2u}{dx^2} = 6x - 30 = \pm 2\sqrt{57}$. Hence it appears that the function has a *minimum*, and also a *maximum* value; the former corresponding to $x = \frac{15 + \sqrt{57}}{3}$, and the latter to $x = \frac{15 - \sqrt{57}}{3}$.

If $x = \frac{15 + \sqrt{57}}{3}$, $u = -30 - \frac{38}{9}\sqrt{57}$, a *minimum.*

If $x = \frac{15 - \sqrt{57}}{3}$, $u = -30 + \frac{38}{9}\sqrt{57}$, a *maximum.*

Ex. 4. Let $u = x^5 - 5x^4 + 5x^3 + 1$;

then $\frac{du}{dx} = 5x^4 - 20x^3 + 15x^2 = 5x^2(x^2 - 4x + 3)$;

$$\frac{d^2u}{dx^2} = 20x^3 - 60x^2 + 30x = 10x(2x^2 - 6x + 3).$$

The equation $\frac{du}{dx} = 5x^2(x^2 - 4x + 3) = 0$,

gives four values of x, viz. $x = 3, x = 1$, the other two are $= 0$.

These being substituted in $\frac{d^2u}{dx^2}$, show that the function has a *maximum* and *minimum:*

when $x = 3$, $u = -26$, a *minimum;*

$x = 1$, $u = 2$, a *maximum;*

when $x = 0$, then $\frac{d^2u}{dx^2}$ vanishes, therefore there is neither *maximum* or *minimum* in this case.

Ex. 5. To determine the *maxima* and *minima* values of the function $y = x^x$; we have found (art. 24, ex. 2), that

$$\frac{dy}{dx} = x^x(1 + \text{l}.\,x);$$

and hence $\frac{d^2y}{dx^2} = x^x \left\{ \frac{1}{x} + (1 + \text{l}.\,x)^2 \right\}$;

The function x^x cannot be $= 0$; we must therefore put $1 + \text{l}.\,x = 0$;

hence $\text{l}.\,x = -1$, and $x = e^{-1} = \frac{1}{e}$.

This value of x, substituted in the second differential coefficient, makes

$$\frac{d^2u}{dx^2} = \left(\frac{1}{e}\right)^{\frac{1}{e}} . e, \text{ a positive quantity};$$

therefore, when $x = \frac{1}{e}$, $x^x = \left(\frac{1}{e}\right)^{\frac{1}{e}}$, a *minimum.*

Ex. 6. To find the greatest space that can be enclosed by four given straight lines:

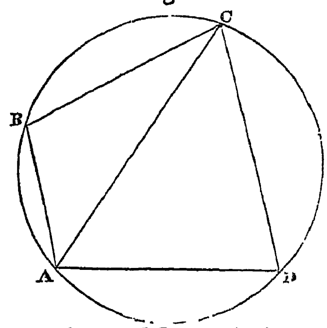
Let the given lines be AB $= a$, BC $= b$, CD $= e$, DA $= f$: Let $x =$ angle B, $v =$ angle D, $y =$ the area ABCD: Draw the diagonal AC.

By trigonometry, $a^2 + b^2 - 2ab \cos x = \text{AC}^2$,

$e^2 + f^2 - 2ef \cos v = \text{AC}^2$;

Hence, $2ab \cos x - 2ef \cos v = a^2 + b^2 - e^2 - f^2$.........(1)

Fig. 1.



And because trian. ABC $= \frac{1}{2}ab \sin x$; trian. ADC $= \frac{1}{2}ef \sin v$,

therefore, $y = \frac{1}{2}ab \sin x + \frac{1}{2}ef \sin v$.........................(2)

This last equation by differentiation gives, by the nature of a maximum,

$\frac{dy}{dx} = \frac{1}{2}ab \cos x + \frac{1}{2}ef \frac{dv}{dx} \cos v = 0$.......................(3)

By differentiating equation (1), we find

$$ab dx \sin x - ef dv \sin v = 0;$$

and hence $ef \frac{dv}{dx} = ab \frac{\sin x}{\sin v}$:

Therefore, from eq. (3), $ab \left\{ \cos x + \frac{\sin x \cos v}{\sin v} \right\} = 0$;

and hence $\sin v \cos x + \cos v \sin x = 0$;

that is (Algebra, art. 239), $\sin(x + v) = 0$, and $x + v = \pi$.

Thus it appears that the opposite angles B, D must together make two right angles; therefore the figure will be a *maximum* when it is inscribed in a circle; and since in this case

$$\cos x = -\cos v, \ \sin x = \sin v;$$

from equations (1) and (2),

$2(ab + ef) \cos x = a^2 + b^2 - e^2 - f^2$,

$2(ab + ef) \sin x = 4y$.

By squaring both sides of these equations, and adding, and observing that $\cos^2 x + \sin^2 x = 1$, we have

$4(ab + ef)^2 = (a^2 + b^2 - e^2 - f^2)^2 + 16y^2$,

and $16y^2 = 4(ab + ef)^2 - (a^2 + b^2 - e^2 - f^2)^2$.

The right-hand side of this formula admits of being resolved into these two factors, viz.

$2ab + 2ef + a^2 + b^2 - e^2 - f^2 = (a + b)^2 - (e - f)^2$,

$2ab + 2ef - a^2 - b^2 + e^2 + f^2 = (e + f)^2 - (a - b)^2$;

and these again admit of this further resolution,

$(a + b + e - f)(a + b - e + f)$,

$(e + f + a - b)(e + f - a + b)$;

If we now put $s = \frac{1}{2}(a + b + e + f)$,

we have $a + b + e - f = 2(s - f)$,

$a + b - e + f = 2(s - e)$,

$e + f + a - b = 2(s - b)$,

$e + f - a + b = 2(s - a)$.

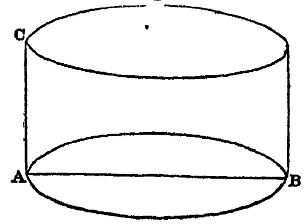
Hence $16y^2 = 16(s - a)(s - b)(s - e)(s - f)$;

and $y = \sqrt{(s - a)(s - b)(s - e)(s - f)}$.

We have now found by the calculus an elegant geometrical theorem.

Ex. 7. To determine the dimensions of a cylindric measure, open at top, which shall contain a given quantity of grain, liquor, &c. under the least internal superficies.

Fig. 2.



Direct Method.

Let $x =$ AB be the diameter of the base, $v =$ AC its depth, π the number 3·1416 (viz. half the circumference of a circle whose rad. $= 1$), and c the content of the cylinder. By GEOMETRY, the area of the base $= \frac{\pi x^2}{4}$, and its circumference $= \pi x$, and the internal curved surface of the cylinder $= v\pi x$. Now, the content of the cylinder $c = \frac{\pi x^2 v}{4}$; and therefore $v = \frac{4c}{\pi x^2}$; therefore the internal curved surface $= \frac{4c}{x}$; and putting y for the whole inside surface of the measure,

$$y = \frac{\pi x^2}{4} + \frac{4c}{x},$$

$$\text{therefore, } \frac{dy}{dx} = \frac{\pi x}{2} - \frac{4c}{x^2} = 0;$$

$$\frac{d^2y}{dx^2} = \frac{\pi}{2} + \frac{8c}{x^3}.$$

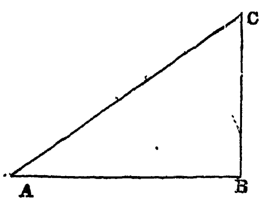
The first of these equations gives

$$\pi x^3 = 8c = 2\pi x^2 v, \text{ and } x = 2v;$$

hence the diameter of the base must be twice the depth: The second differential co-efficient being a positive quantity, shows the surface to be a *minimum*.

Ex. 8. A candle stands on a horizontal table, directly over a point at a given distance from a small object on the table; what ought to be the height of the flame when the object is illuminated the most possible.

Fig. 3.



Let A be the object on the table, B the point under the candle, and C the flame, considered as condensed at a point. The intensity of the illumination on the object A depends on its distance from C, and on the angle which the rays make with the surface (supposed to be horizontal). By the principles of optics, the intensity at different distances, the angle of obliquity being the same, will be inversely as the square of the distance; and with different degrees of obliquity, the distance being the same, as the sine of the angle which the rays make with the surface. Therefore the intensity, as depending on both obliquity and distance, will be expressed by

$$\frac{1}{AC^2} \sin CAB = \frac{BC}{AC^3}.$$

Put $a =$ AB, $x = \sin$ CAB, and let y denote the illuminating power on the surface at A; then

$$y = \frac{BC}{AC} \times \frac{AB^2}{AC^2} \times \frac{1}{AB^2} = \frac{\sin x \cos^2 x}{a^2},$$

$$\frac{dy}{dx} = \left\{ \cos^3 x - 2 \sin^2 x \cos x \right\} \frac{1}{a^2} = 0;$$

hence, $2 \sin^2 x \cos x = \cos^3 x$,

$$\text{and } \frac{\sin^2 x}{\cos^2 x} = \frac{1 - \cos 2x}{1 + \cos 2x} = \tfrac{1}{2}, \text{ and } \cos 2x = \tfrac{1}{3}.$$

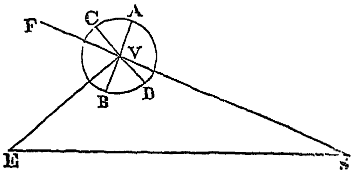
By the trigonometrical tables, $2x = 70° 32'$, and $x = 35° 16'$; this gives BC $=$ AB $\times$ .71 nearly: so that the height of the flame must be about $\frac{7}{10}$ of the distance AB.

Ex. 9. To find the position of the planet Venus in respect of the earth and sun when her light is the greatest.

The planet does not appear brightest when her disc is perfectly round; she is then too remote to produce that effect; and besides, she is seen in the direction of the sun. In her inferior conjunctions her crescent is too narrow, almost the whole illuminated part being turned towards the sun. It is therefore in some intermediate position, which is to be determined, that she is brightest.

Let S be the sun, E the earth, and ACBD Venus, ADB its illuminated hemisphere which is turned towards the sun, and CBD its hemisphere towards the earth: produce S V to F.

Fig. 4.



The portion of the illuminated surface turned towards the earth is contained between two planes DV, BV, perpendicular to the plane EVS; and this surface will manifestly be projected into a crescent, the breadth of which is the versed sine of the angle BVD, which is equal to EVF, because if BVE be added to both, each is a right angle. Now the area of the crescent is always as its breadth; therefore, the whole disk being taken as an unit, the illuminated part of it will be expressed by the versed sine of the angle EVF, or by $1 + \cos$ EVS.

Again, the brightness of the planet at different distances is inversely as the square of the distance; therefore the brightness depending on its position in respect of the sun and its distance from the earth jointly, will be proportional to $\frac{1 + \cos EVS}{EV^2}$.

Let $a =$ ES the distance of the earth from the sun,
$b =$ VS the distance of Venus from the sun,
$x =$ VE the distance of Venus from the earth;

$$\text{Then, } \cos EVS = \frac{x^2 + b^2 - a^2}{2bx},$$

$$\text{and } 1 + \cos EVS = \frac{x^2 + 2bx + b^2 - a^2}{2bx}$$

$$= \frac{(x + b + a)(x + b - a)}{2bx};$$

therefore, putting y to denote the brightness of the planet,

$$y = \frac{(x + b + a)(x + b - a)}{2bx^3} \text{ a } maximum;$$

and this, by differentiation, gives

$$\frac{dy}{dx} = \frac{(x + b + a)(x + b - a)}{2bx^3} \left\{ \frac{1}{x + b + a} + \frac{1}{x + b - a} - \frac{3}{x} \right\} = 0;$$

$$\text{and hence, } 3(a^2 - b^2) - 4bx - x^2 = 0;$$

$$x^2 + 4bx = 3(a^2 - b^2),$$

$$x = \pm\sqrt{3a^2 + b^2} - 2b.$$

The negative value of x is not applicable, and we have

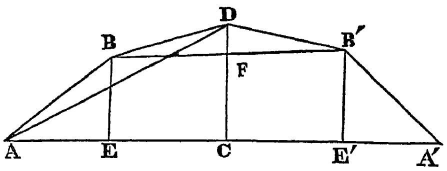
$$x = \sqrt{3a^2 + b^2} - 2b.$$

In numbers, $a = 10000$, $b = 7233$, therefore $x = 4304$, the angles E $= 39° 43' 30''$, V $= 117° 55' 20''$, S $= 22° 21' 10''$.

Ex. 10. Let ABDB'A' be a kirb roof supported by

four rafters AB, BD, DB′, B′A′, two and two of which are equal, viz. AB = A′B′, and BD = B′D, and all perfectly free to turn about the points A, B, D, B′, A′, as joints. Suppose also that AA′ the span, and DC the height of the roof, are given, and that AB has to BD a given ratio. Determine the position of the rafters when by their weight they form an equilibrium.

Fig. 5.



Suppose the roof to be inverted so as to form a polygon hanging suspended from the points A, A′; by a known principle in statics, when it forms an equilibrium, the centre of gravity of the mass of matter in the polygon will be the lowest possible. If now the polygon were reversed and placed in its position as a roof, without changing the angles at the joints, the equilibrium would not be disturbed, and in this position the centre of gravity would be the highest possible.

Draw a line from B to B′, which will be parallel to AA′; and draw the perpendiculars BE, B′E′. Put the angle BAC = B′A′C = x, DBF = DB′F = v; let the given ratio of AB to BD be that of a given number m to a given number n; these numbers may represent the length, also the weight, of the rafters, which may be supposed placed in their centres of gravity, or middle of the beams.

By trigonometry, BE = $m \sin x$, DF = $n \sin v$, therefore DC = $m \sin x + n \sin v$; and, by statics, the height of the centre of gravity of AB, also of A′B′, above AA will be $\frac{1}{2}$ BE = $\frac{1}{2} m \sin x$, and the height of the centre of gravity of BD, also of B′D, will be $\frac{1}{2}$ (BE + DC) = $m \sin x + \frac{1}{2} n \sin v$; and since the distance of the common centre of gravity of all the beams from AA′ will be found by multiplying the distance of each centre by the mass, supposed placed at that centre, and adding the results into one sum, and dividing by the sum of all the masses; the height of the centre of gravity of the whole system of beams above AA′ will be

$$\frac{m^2 \sin x + n\,(2\,m \sin x + n \sin v)}{2\,(m + n)}.$$

Let this height be denoted by y; then, rejecting the constant denominator $2\,(m + n)$,

$y = (m^2 + 2\,mn) \sin x + n^2 \sin v$, a maximum; and since AC, half the span of the roof, is a given quantity, we have

$$m \cos x + n \cos v = \text{AC, } a \textit{ constant.}$$

From the first equation,

$$\frac{dy}{dx} = (m^2 + 2\,mn) \cos x + n^2 \cos v \frac{dv}{dx} = 0;$$

and from the second,

$$m \sin x + n \sin v \frac{dv}{dx} = 0; \text{ hence } \frac{dv}{dx} = -\frac{m \sin x}{n \sin v}.$$

This value of $\frac{dv}{dx}$ being substituted in the value of $\frac{dy}{dx}$, we obtain

$$(m^2 + 2\,mn) \cos x - \frac{mn \cos v \sin x}{\sin v} = 0;$$

and from this again,

$$\frac{\tan x}{\tan v} = \frac{m}{n} + 2 \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(1.)$$

This formula expresses a property of all roofs made of four beams, which are equal two and two, when by their position they form an equilibrium.

Join AD, and put γ = angle DAC which is known, because $\tan \gamma = \frac{\text{DC}}{\text{AC}}$. The angle BAD $= x - \gamma$, and BDA $= \gamma - v$. Now, in the triangle ABD, sin A : sin D = DB : BA, that is, $\sin (x - \gamma) : \sin (\gamma - v) = n : m$; therefore,

$$\frac{\sin (x - \gamma)}{\sin (\gamma - v)} = \frac{n}{m} \ldots\ldots\ldots\ldots(2.)$$

These equations (1), (2), determine the angles x, v, when the ratio of AB to BD is given; from their form, the angles may be easily found by trials in the trigonometrical tables. The elimination of one of the angles would produce an equation of the fourth degree; for this reason, the method of trials is the best way of proceeding. When the angles x and v are known, every thing else may be readily found.

If we suppose the beams AB, BD, to be of equal length, then $m = n$, and our two equations become

$$\frac{\tan x}{\tan v} = 3, \quad \sin (x - \gamma) = \sin (\gamma - v).$$

In this case, $x + v = 2\gamma$; then, from the equation

$$\frac{\tan x}{\tan v} = \frac{\sin x \cos v}{\cos x \sin v} = 3,$$

we get $$\frac{\sin x \cos v - \cos x \sin v}{\sin x \cos v + \cos x \sin v} = \frac{\sin (x - v)}{\sin (x + v)} = \tfrac{1}{2};$$

and hence $\sin (x - v) = \frac{1}{2} \sin (x + v) = \frac{1}{2} \sin 2\gamma$; and putting for v its value $2\gamma - x$,

$$\sin 2\,(x - \gamma) = \tfrac{1}{2} \sin 2\gamma.$$

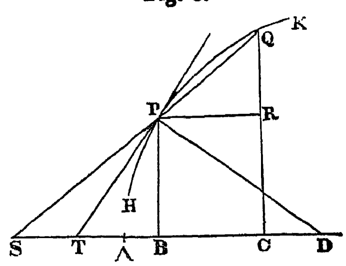
This determines the angle x, and $v = 2\gamma - x$.

The theory of equilibriums opens a wide field for the application of the calculus, as must be evident from the preceding solution; but our limits will not permit us to enter on it farther.

Determination of Tangents to Curves.

65. Let HPK be any curve referred to an axis AC; and let AB = x and PB = y be the co-ordinates of any point P in the curve; the point A being the origin of the abscisses. Let PT, a tangent to the curve at P, meet the axis in T; and let SPQ, any straight line drawn through P, meet the curve in Q and the axis in S. Draw QC perpendicular to the axis, and PR perpendicular to QC; and let PR = BC = h, and QC = y', the ordinate corresponding to the absciss $x + h$.

Fig. 6.



By similar triangles, QR : RP = PB : BS, that is,

$$y' - y : h = y : \text{BS}.$$

Now, by Taylor's theorem (art. 31),

$$y' - y = \frac{dy}{dx} h + \frac{d^2y}{d^2x} h^2 + \text{\&c.}$$

hence, dividing the first antecedent and consequent by h,

$$\frac{dy}{dx}+\frac{d^2y}{dx^2}h+\text{\&c.}:1=y:\text{BS}.$$

This proposition holds true whatever be the magnitude of h, the increment of x. But now let us suppose h to decrease continually; the point Q will approach to P, and the line QPS approaching to coincidence with PT, the point S will approach to T; and when h vanishes, Q will be at P, and S at T, and BS will have become BT; our proportion will now be

$$\frac{dy}{dx}:1=y:\text{BT}.$$

The line BT, between the ordinate PB and tangent PT, is called the *subtangent;* from this proportion it appears, that x and y being co-ordinates at any point in the curve,

$$\text{BT, the subtangent,}=y\div\frac{dy}{dx}=y\frac{dx}{dy};\ldots\ldots\ldots\ldots(1)$$

that is, the subtangent is equal to the ordinate divided by its differential co-efficient; or it is a third proportional to the differential of the ordinate, the differential of the abscissa and the ordinate. The subtangent being known, the position of the tangent is determined.

Let PD, a perpendicular to the tangent at P, and consequently to the curve, meet the axis in D; the line PD is called a *normal* to the curve; and BD, the segment of the axis between the ordinate and normal, is called the *subnormal.*

The triangles TBP, PBD are similar, therefore

$$\text{TB}:\text{BP}=\text{BP}:\text{BD, or } dx:dy=y:\text{BD},$$

$$\text{hence the } \textit{subnormal}\ \text{BD}=y\frac{dy}{dx}\ldots\ldots\ldots(2).$$

Because the tangent of the angle $\text{PTB}=\frac{\text{PB}}{\text{TB}}$, and the tangent of the angle $\text{PDB}=\frac{\text{PB}}{\text{BD}}$; therefore,

$$\tan \textit{angle}\ \text{T}=\frac{dy}{dx}, \text{ and } \tan \text{D}=\frac{dx}{dy}\ldots\ldots\ldots(3).$$

In the right-angled triangles TBP, PBD, we have $\text{PT}^2=\text{PB}^2+\text{BT}^2$, and $\text{PD}^2=\text{PB}^2+\text{BD}^2$; therefore,

$$\textit{tangent}\ \text{PT}=y\sqrt{1+\frac{dx^2}{dy^2}}\ldots\ldots\ldots\ldots\ldots\ldots(4)$$

$$\textit{normal}\ \text{PD}=y\sqrt{1+\frac{dy^2}{dx^2}}\ldots\ldots\ldots\ldots\ldots\ldots(5)$$

66. We shall now apply these general formulæ to some particular curves.

Ex. 1. Let the curve be the parabola, and supposing AC to be the axis, and A its vertex: by the nature of the curve, putting a for the parameter, $y^2=ax$,

$$\text{hence } 2ydy=adx;\ \frac{dx}{dy}=\frac{2y}{a},$$

$$\text{subtan. BT}=\frac{dx}{dy}y=\frac{2y^2}{a}=\frac{2ax}{a}=2x;$$

that is, the subtangent is double the absciss AB.

Again, for the subnormal, we have

$$\text{subnor. BD}=\frac{dy}{dx}y=\frac{adx}{2dx}=\frac{a}{2}.$$

Thus it appears that the subnormal is constant, and equal to half the parameter.

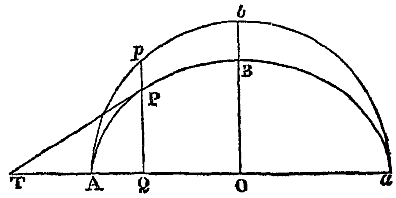
Ex. 2. Let the curve be an ellipse, of which OA half the greater axis $=a$, OB half the lesser axis $=b$; and supposing the origin of the co-ordinates to be at O the centre, let $\text{OQ}=x$, $\text{PQ}=y$. By the nature of the curve,

$$a^2:b^2=(a+x)(a-x):y^2 \text{ (Conics)};$$

$$\text{hence } y^2=\frac{b^2}{a^2}(a^2-x^2), \text{ and } ydy=-\frac{b^2xdx}{a^2};$$

$$\text{and subtan. QT}=\frac{dx}{dy}y=-\frac{a^2y^2}{b^2x}=-\frac{a^2-x^2}{x}=-\left(\frac{a^2}{x}-x\right).$$

Fig. 7.



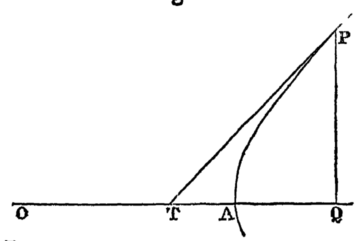
The general formula for the subtangent was found on the hypothesis that it was on the same side of the ordinate as the absciss; in this case they are supposed to be on opposite sides, and hence its value has the negative sign; leaving the direction of the subtangent in respect of the absciss out of consideration, we have

$$\text{QT}=\frac{a^2}{x}-x, \text{ and OT}=\frac{a^2}{x},$$

hence it appears that $\text{OQ}:\text{OA}=\text{OA}:\text{OT}$.

When the axes are equal, the ellipse becomes a circle, but the subtangent is independent of the ratio of the axes.

Fig. 8.



Ex. 3. Let the curve be the hyperbola, of which $a=\text{OA}$ the semitransverse axis, and $b=$ the semiconjugate; then, putting $\text{OQ}=x$, and $\text{PQ}=y$, we have (by Conics),

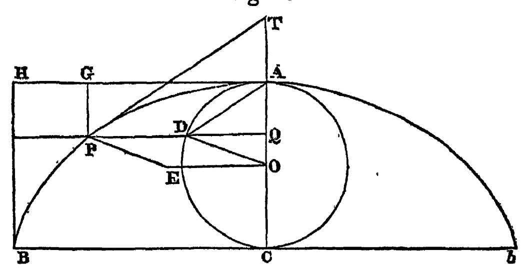
$$y^2=\frac{b^2}{a^2}(x^2-a^2),\quad ydy=\frac{b^2}{a^2}xdx;$$

$$\text{subtan. QT}=\frac{dx}{dy}y=\frac{a^2y^2}{b^2x}=\frac{x^2-a^2}{x}=x-\frac{a^2}{x};$$

$$\text{hence OT}=\text{OQ}-\text{QT}=\frac{a^2}{x}.$$

This shows that the tangent always passes between the centre and the vertex when x has a finite value; but when x becomes infinite, then $\text{OT}=0$, and the tangent becomes an asymptote to the hyperbola.

Fig. 9.



Ex. 4. We shall next draw a tangent to the cycloid; but first the nature of the curve must be expressed analytically. Conceive a circle to roll along a straight line, moving always in the same plane, just as the wheel of a carriage rolls along a straight road. By this motion any given point in the circumference of the circle will describe

a continuous curve in that plane, which will meet the line along which it rolls at intervals equal to its circumference.

Let bB be the line along which a circle CDA rolls, beginning its motion from a point of contact b, and completing a revolution when it has come to B. The point of the circumference which was in contact with the line at b will then have generated the curve line bAB. This is the *cycloid*, and the line bB its *base*.

Let ADC be a fixed circle in the position of the *generating* circle when it has completed half a revolution, O its centre, and AC its diameter, called the axis of the cycloid. Let AD be any arc of this circle. Draw the radius OD. When the generating circle, by rolling along CB from the position C, has passed over a distance equal to the arc AD, the centre O will have generated a straight line OE parallel to CB, and equal to the same arc AD; moreover, the moveable radius, which was coincident with OA, will, by the rotation of the circle, have come into a position EP, parallel to OD, because the angular motion of the radius about the moving point E will always be proportional to the arc of the circle that has been applied to the base, that is, by hypothesis, to the arc AD; and since the lines OD, EP are equal and parallel, a straight line drawn from P through D, meeting AC in Q, will be parallel to EO, and therefore perpendicular to AC; and since PD = OE = arc AD, it follows that PQ, any ordinate to the axis AC, is equal to the sum of the arc AD and its sine DQ. This is the distinguishing property of a cycloid. To express it by equations, let the radius of the generating circle be a, and the angle AOD $= v$, then PD = arc AD $= av$, and DQ $= a \sin v$, so that, putting AQ $= x$, and PQ $= y$, we have for the equations of the curve

$$x = a\,(1 - \cos v), \quad y = a\,(v + \sin v);$$

and from these every property of the curve may be investigated.

To determine the tangent: by differentiation,

$$dx = adv \sin v, \quad dy = adv\,(1 + \cos v), \quad \frac{dx}{dy} = \frac{\sin v}{1 + \cos v},$$

$$\text{subtan QT} = y\frac{dx}{dy} = \frac{(v + \sin v)\sin v}{1 + \cos v} = \frac{\text{PQ}\,.\,\text{QD}}{\text{CQ}};$$

hence CQ : DQ = PQ : QT.

But by the nature of the circle CQ : DQ = DQ : QA; therefore PQ : QT = DQ : QA; hence the triangles PQT, DQA are similar, and the tangent PT is parallel to the chord DA.

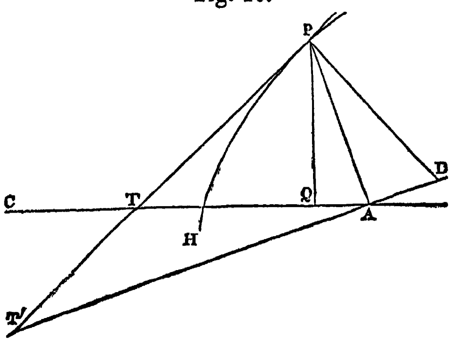
Ex. 5. In the logarithmic curve of which the equation is $y = a^x$, we have $dy = a^x \,.\, \text{l.}\, a \,.\, dx = y\,\text{l.}\, a \,.\, dx$; therefore

$$\frac{dx}{dy}y = \frac{1}{\text{l.}\, a} = \text{subtangent.}$$

Hence it appears that the subtangent is a line of a constant given length.

67. To find a formula for the subtangent and normal of curves whose nature is expressed by a polar equation.

Fig. 10.



Let HPK be such a curve, generated by the revolution of a variable radius AP about a given point A in AC, a line given in position. Through A draw AT' perpendicular to AP; let a tangent to the curve at P meet this line in T' and the axis in T; draw PQ perpendicular to the axis AC, and draw the normal PD, meeting T'A in D. Then AT' is the subtangent and AD the subnormal. Let AQ $= x$, PQ $= y$, the revolving radius AP $= r$, the variable angle PAC $= v$, and the angle PTA $= t$. The lines x, y, r are now to be considered as functions of the angle v.

The angle T'PA being the supplement of the sum of PTA and PAT; that is, of $v + t$, we have (ALGEBRA, art. 236 and 242),

$$\tan \text{angle T'PA} = -\tan(v + t) = \frac{\tan v + \tan t}{\tan v \tan t - 1}.$$

$$\text{Now } \tan v = \frac{y}{x}, \text{ and } \tan t = \frac{\text{PQ}}{\text{TQ}} = -\frac{dy}{dx};$$

$$\text{therefore } \tan \text{T'PA} = \frac{\frac{y}{x} - \frac{dy}{dx}}{-\frac{ydy}{xdx} - 1} = \frac{xdy - ydx}{xdx + ydy}.$$

$$\text{Again, } \frac{xdy - ydx}{x^2} = d\left(\frac{y}{x}\right) = d\,(\tan v) = \frac{dv}{\cos^2 v},$$

$$\text{therefore } xdy - ydx = dv\frac{x^2}{\cos^2 v} = r^2 dv;$$

$$\text{and } xdx + ydy = \tfrac{1}{2}d\,(x^2 + y^2) = \tfrac{1}{2}d\,(r^2) = rdr;$$

$$\text{therefore } \tan \text{T'PA} = \frac{r^2 dv}{rdr} = \frac{rdv}{dr};$$

and since by trigonometry T'A = AP tan TPA, therefore

$$\text{subtangent T'A} = \frac{dv}{dr}r^2;$$

also, since T'A : AP = AP : AD; therefore

$$\text{subnormal AD} = \frac{dr}{dv}.$$

Ex. Let the curve PH be the spiral of Archimedes, the nature of which is defined by the equation $2\pi r = av$, where $\pi = 2$ right angles, and a is a given line, viz. the value of r when $v = 2\pi$. In this case

$$\text{subtangent} = \frac{dv}{dr}\,.\,r^2 = \frac{2\pi r^2}{a}.$$

68. In some curves the segment of the axis between the origin of the co-ordinates and the tangent increases with the variable x, and may exceed any given line. In others the tangent cuts the axis always at a finite distance from the origin; it is then an *asymptote* to the curve. If from the subtangent QT $= \frac{dx}{dy}y$ (fig. 8) the absciss AQ $= x$ be subtracted, the remainder $\frac{dx}{dy}y - x$ is the general expression for AT. Now if when x is infinite this expression is finite, we may conclude that the curve has asymptotes; but if it be infinite, the curve has no asymptotes.

In the conic hyperbola we found (ex. 3, art. 66) $\frac{dx}{dy}y = x - \frac{a^2}{x^2}$; therefore $\frac{dx}{dy}y - x = -\frac{a^2}{x^2}$; when x is infinite, the expression $-\frac{a^2}{x} = 0$, hence it follows that the hyperbola has an asymptote which passes through the centre.

In the parabola, ex. 1, we found $\frac{dx}{dy}y = \frac{2y^2}{a}$, therefore

Direct Method.

$\frac{dx}{dy}y - x = \frac{2y^2}{a} - x = 2x - x = x$. When x is infinite this quantity is also infinite, therefore the parabola has no asymptote.

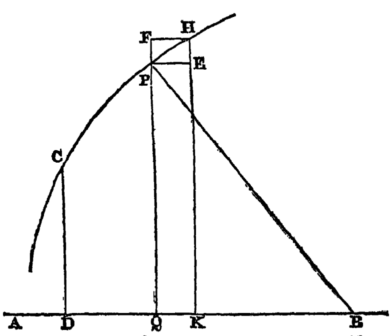
The method of drawing tangents to curves is an important branch of the theory of curve lines. It serves also to determine their greatest and least ordinates (which may also be found by the theory of *maxima* and *minima*), and many other circumstances relating to their figure.

Differential of the Area of a Curvilineal Space, and of the Arc of a Curve.

69. In curve lines it is convenient to consider x, one of the co-ordinates, as an independent variable quantity; and any area having an arc of the curve for a boundary, also the arc, and in general every other variable quantity connected with the curve, as functions of that variable. If the curve be expressed by a polar equation, the angle which the revolving radius makes with the variable may be taken as the independent variable, and the co-ordinates and other variable quantities related to the curve as functions of that angle.

We begin by investigating a formula for the area.

Fig. 11.



Let AB be the axis of any curve CP, A and C given points in the axis and curve, PQ, HK any two variable ordinates, and CD an ordinate given in position at the given point C; draw PE and HF perpendiculars to HK, PQ.

Put $AQ = x$, $PQ = y$, *curvilineal space* $PQDC = s$;
$AK = x'$, $HK = y'$, $HKDC = s'$;
then $QK = x' - x$, and $PHKQ = s' - s$.

The space PHKQ is greater than the rectangle PEKQ, but less than the rectangle FHKQ (supposing y to increase from the position PQ to HK), therefore,

$$s' - s > (x' - x)\,y, \quad s' - s < (x' - x)\,y';$$

$$\text{and } \frac{s' - s}{x' - x} > y, \quad \frac{s' - s}{x' - x} < y'.$$

Hence, since when HK approaches to coincidence with PQ, y' approaches to equality with y, we have

$$\frac{ds}{dx} = \lim.\,\frac{s' - s}{x' - x} = y,$$

and $ds = ydx$..............................(1).

Thus it appears that *The differential of a curvilineal area is the product of the ordinate and the differential of the absciss.*

In the formula just found, the ordinates have been supposed perpendicular to the axis. If they be oblique, let α be the angle of inclination; then $s' - s$ will be greater than $(x' - x)\,y \,.\, \sin\alpha$, but less than $(x' - x)\,y' \,.\, \sin\alpha$; and hence, reasoning as before, we find

$ds = \sin\alpha \,.\, ydx$..........................(2).

70. To find a formula applicable when the nature of the curve is expressed by a polar equation, let B be the pole, and PB the variable radius.

Direct Method.

Put $PB = r$, the angle $PBQ = v$, and the curvilineal space $PCDB = s$; also let $BQ = x$, $PQ = y$, then

$$ds = d\,(\text{space } CDQP) + d\,(\text{triangle } PQB).$$

Now d (space CDQP) $= -\,ydx$, which is negative, because x decreases when the space increases; and d (triangle PQB) $= d\left(\frac{1}{2}xy\right) = \frac{1}{2}ydx + \frac{1}{2}xdy$; therefore,

$$ds = -\,ydx + \tfrac{1}{2}ydx + \tfrac{1}{2}xdy = \tfrac{1}{2}\,(xdy - ydx)$$
$$= \tfrac{1}{2}x^2 d\left(\frac{y}{x}\right) \text{ (art. 12).}$$

But in the right-angled triangle PBQ,

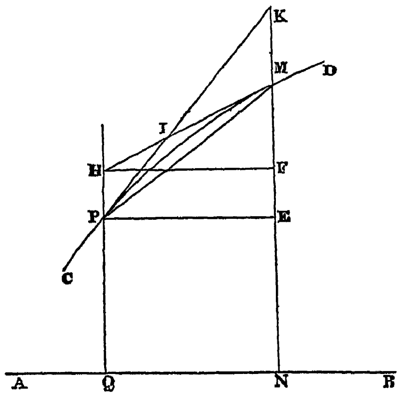
$$BQ = x = r\cos v, \quad \frac{y}{x} = \tan v, \quad d\left(\frac{y}{x}\right) = \frac{dv}{\cos^2 v} \text{ (art. 22);}$$

hence $ds = \frac{1}{2}r^2 dv$..........................(3).

In this case *The differential of the area is half the product of the square of the revolving radius, and the differential of the angle which it makes with the axis.*

71. We have already found (art. 23) various expressions for the differential of the arc of one particular curve, viz. the circle. We shall now investigate general expressions for the differential of the arc of any curve. For this purpose it will be convenient to establish the following geometrical proposition.

Fig. 12.



Let CPMD be a curve, that between the points P and M continually approaches to or continually recedes from an axis AB. Let PQ, MN be ordinates to the axis at the extremities of the arc PM, and PK, MH tangents to the curve at the points P, M, meeting the ordinates in K and H: The length of the arc is always of an intermediate magnitude between the lengths of the tangents PK, MH.

Draw the chord PM, and let I be the intersection of the tangents. It is easy to see that PK, one of the tangents, meets the parallel ordinates in an angle K more acute than M, the angle made by the chord PM and ordinate MN; and the other in an angle H less acute; therefore the chord will be less than the former and greater than the latter. Now the arc is greater than the chord; therefore MH, the least of the tangents, is less than the arc PM.

Again, in the two triangles PIH, MIK, it is evident that the two parts PI, IK, of the longest tangent, are respectively greater than HI, IM, those of the shorter; therefore PK is longer than the sum of PI and IM; but the arc PM is by an axiom of geometry less than the sum of PI and IM, therefore the tangent PK is greater than the arc PM.

72. Let A be a given point in the axis, and C in the curve; draw PE, HF parallel to AB; put $AQ = x$, $AN = x'$, $PQ = y$, $CP = z$, $CM = z'$; then $PE = x' - x$, and arc $PM = z' - z$. Because $PM = z' - z$ is less than PK, but greater than MH, therefore

$$\frac{z'-z}{x'-x}<\frac{PK}{PE}, \text{ and } \frac{z'-z}{x'-x}>\frac{HM}{HF}.$$

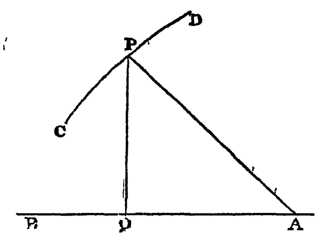
Now $\frac{PK}{PE}$ and $\frac{HM}{HF}$ are the secants of the angles KPE and MHF; therefore the ratio $\frac{z'-z}{x'-x}$ is expressed by a quantity less than the secant of one of these angles, and greater than the secant of the other angle. Suppose now $z'-z$ and $x'-x$, the terms of the ratio, to be continually diminished; the angles at H and P will approach to equality, and at last become equal, therefore the limit of the ratio, viz. $\frac{dz}{dx}$, is equal to the secant of the angle KPE; but it was shown (art. 65) that the tangent of the angle which a line touching a curve makes with the axis, or any line parallel to the axis, is equal to $\frac{dy}{dx}$, and consequently its secant to $\sqrt{1+\frac{dy^2}{dx^2}}$; therefore

$$\frac{dz}{dx}=\sqrt{1+\frac{dy^2}{dx^2}} \text{ and } dz=\sqrt{dx^2+dy^2}\ldots\ldots\ldots\ldots(1)$$

Hence it appears that *The square of the differential of the arc of a curve is equal to the sum of the squares of the differentials of its rectangular co-ordinates.*

73. In the case of curves expressed by a polar equation, let A be the given point about which the variable radius

Fig. 13.



AP turns; put v for the variable angle which the line AP $= r$ makes with AB, a line given in position; let the rectangular co-ordinates be AQ $= x$, PQ $= y$; then

$$x=r\cos v,\ y=r\sin v;$$

$$dx=-r\sin v\,dv+\cos v\,dr=-ydv+\frac{x}{r}dr;$$

$$dy=r\cos v\,dv+\sin v\,dr=xdv+\frac{y}{r}dr;$$

$$dx^2=y^2dv^2+\frac{x^2}{r^2}dr^2-\frac{2xy}{r}dvdr;$$

$$dy^2=x^2dv^2+\frac{y^2}{r^2}dr^2+\frac{2xy}{r}dvdr;$$

$$\text{therefore, } dx^2+dy^2=(x^2+y^2)\left(dv^2+\frac{dr^2}{r^2}\right).$$

But $dx^2+dy^2=dz^2$, and $x^2+y^2=r^2$;
therefore, $dz^2=r^2dv^2+dr^2$,

$$\text{and } dz=\sqrt{r^2dv^2+dr^2}\ldots\ldots\ldots\ldots\ldots\ldots(2)$$

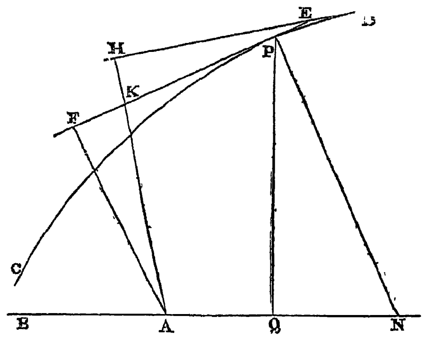
This formula gives the differential of an arc of a curve in terms of the differentials of the variable *radius vector,* and of the angle which it makes with the axis.

74. We shall now give a method of defining a curve by a polar equation, which leads to a simple and elegant expression for the differential of an arc of the curve.

Let CPD be any curve, and A a given point in AB, a line given by position; draw a tangent PF at any point P in the curve, and a perpendicular AF from the given point A on the tangent; if now we know the relation between the perpendicular AF, and the angle FAB, which it makes with the line AB, the length of the perpendicular corresponding to any given value of the angle can be found; thus the position of the tangent will be known; the calculus gives a general formula for PF, the segment of the tangent between the point of contact and its intersection with the perpendicular; thus the point of contact P is known, and in this way may any number of points in the curve be determined.

75. Let D be another point in the curve, DH a tangent, and AH a perpendicular on the tangent, and let us put angle FAB $= u$, perp. AF $= p$, tan PF $= t$, arc CP $= z$;
HAB $= u'$, AH $= p'$, DH $= t'$, CD $= z'$

Fig. 14.



From the position of the lines in the figure,

$$\begin{aligned}HD-FP&=HE+ED-(FK+KE-EP)\\&=PE+ED-FK-(KE-HE).\end{aligned}$$

By trigonometry, FK $=$ AF . tan FAK $= p\tan(u'-u)$; and because in the equiangular triangles AFK, EHK, the angles at A and E are equal, therefore HE $=$ KE . cos $(u-u')$; hence the above equation may be expressed thus,

$$t-t'=PE+ED-p.\tan(u'-u)-\{1-\cos(u'-u)\}KE;$$

and dividing by $u'-u$,

$$\frac{t'-t}{u'-u}=\frac{PE+ED}{u'-u}-p.\frac{\tan(u'-u)}{u'-u}-\frac{1-\cos(u'-u)}{u'-u}KE.$$

Suppose now the point D to approach to coincidence with P, we have these limits to the ratios:

$$\lim.\frac{t'-t}{u'-u}=\frac{dt}{du};\qquad \lim.\frac{PE+ED}{u'-u}=\frac{dz}{du};$$

$$\lim.\frac{\tan(u'-u)}{u'-u}=1;\qquad \lim.\frac{1-\cos(u'-u)}{u'-u}$$

$$=\lim.\frac{2\sin^2\frac{1}{2}(u'-u)}{u'-u}=0;$$

hence, on the whole,

$$\frac{dt}{du}=\frac{dz}{du}-p, \text{ and } dz=dt+pdu,$$

$$\text{or } d(z-t)=pdu.$$

In the figure from which the formula has been investigated, the arc and tangent lie in the same direction from the point of contact. If they had proceeded in contrary directions, the formula would have been $d(z+t)=pdu$, so that, in general,

$$d(z\mp t)=pdu\ldots\ldots\ldots\ldots\ldots(3)$$

The differential of the arc may be expressed independently of t; for

$$AH-AF=KH+AK-AF;$$

Now KH $=$ HE . tan HEK $=$ HE tan $(u'-u)$, and AF $=$ AK cos $(u'-u)$; therefore, dividing by $u'-u$, we have

$$\frac{p'-p}{u'-u} = \mathrm{HE}\,\frac{\tan(u'-u)}{u'-u} + \frac{1-\cos(u'-u)}{u'-u}\,\mathrm{AK}:$$

and, passing to the limits, observing that lim. HE $= t$,

$$\text{lim.}\frac{\tan(u'-u)}{u'-u} = 1, \text{ and lim.}\frac{1-\cos(u'-u)}{u'-u} = 0,$$

we find $\dfrac{dp}{du} = t$; if the tangent and arc lie in contrary directions, then $-\dfrac{dp}{du} = t$, so that, including both cases in one formula, $t = \pm\dfrac{dp}{du}$.

The sign $+$ is to be taken when the arc and tangent lie in the same direction, but the sign $-$ when they have contrary directions; and because $dt = \pm\dfrac{d^2p}{du}$, therefore in every curve

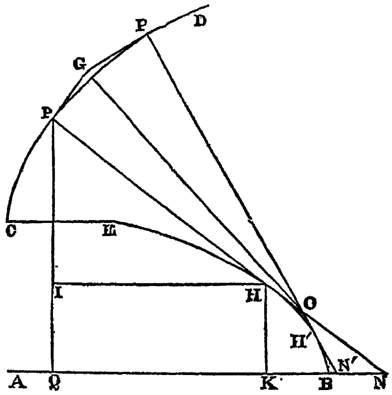
$$dz = pdu + \frac{d^2p}{du^2}\,du = \left(p + \frac{d^2p}{du^2}\right)du \ldots\ldots\ldots\ldots (4)$$

This is the formula which was to be found.

Generation of Curves by Evolution: Radius of Curvature: Evolutes.

76. The method of generating curves by evolution is a geometrical theory invented by Huygens, and given in his *Horologium Oscillatorium.* He explained it upon geometrical principles, for his work appeared many years before the calculus was invented.

Fig. 15.



Let BHE be a model of a plane curve made of a solid material, having some thickness, and let one end of a thread HEC be fastened at a point B on the edge of the model, and applied along its convexity, so as to coincide with it entirely between B and E, the remaining portion EC of the thread forming a straight line touching the curve at E. Suppose now the thread to be gradually unlapped from the curve BE, keeping it always tight; the end C will now describe another curve CPD.

All curves, in which the curvature is neither infinitely great nor infinitely small, may be generated in this way by the evolution of a thread from another curve.

77. The curve EHB, by means of which the curve CPD is generated, is called its EVOLUTE; and the curve CPD thus generated by evolution, is called the INVOLUTE of the other curve.

From the way in which the involute is generated from its evolute, we may infer,

(1.) That PH, the part of the thread disengaged from the arc EH, is a tangent to the evolute at H.

(2.) That the line PH is perpendicular to a tangent to the curve CPD at P, and that at the same time it describes an element of the curve, and an element of a circle whose momentary centre is H and radius HP.

(3.) That to a certain extent the part of the involute adjoining to P, and towards C, is *more* incurvated than a circle whose radius is PH; because, supposing P to proceed towards C, the variable radius PH is gradually becoming shorter. On the other hand, a portion of the curve from P towards D is *less* incurvated than a circle whose radius is CP, because the generating radius is continually becoming longer.

(4.) That since the curvature of the involute on one side of P, and adjoining to it, is less than that of a circle whose radius is PH, and the curvature on the other side of P is greater, it follows that at the point P the curvature of the involute is exactly the same as that of a circle described with the radius HP. The point H is therefore called the *centre of curvature* of the curve CPD in the point P; and PH, its *radius of curvature* at that point; and a circle described with the line PH is the *circle of equal curvature* with the curve at the point P. From the close union of the circle and curve they have been said to *osculate.* It must, however, be kept in mind that the two curves have no common segment; they meet in a geometrical point at P, and separate on both sides of it. We may also infer that the circle of curvature has a more intimate contact with the curve than any other circle that passes through that point.

(5.) That the evolute of a curve is the *locus* of the centre of curvature of every point in the curve.

78. We shall now investigate general formulæ for the radius of curvature, and for the evolute of any curve, by which these may be found when the nature of the curve is known.

Let AB be the common axis of the involute CPD, and its evolute EHB, and A the origin of co-ordinates; let H be the centre, and PH the radius of curvature at P; and H′ the centre, and P′H′ the radius of curvature of another point P′, near the former. Let the radii produced, if necessary, meet the axis in N and N′; and let O be the point in which they intersect each other.

Put AQ $= x$, PQ $= y$, arc CP $= z$, arc CP′ $= z'$, angle PNA $= v$, angle P′N′A $= v'$, rad. of curv. PH $= r$

By trigonometry, PG $=$ OG . sin POG ; P′G $=$ OG . sin P′OG; therefore, $\mathrm{OG} = \dfrac{\mathrm{PG} + \mathrm{P'G}}{\sin \mathrm{POG} + \sin \mathrm{P'OG}}$.

Suppose now the points P′, P to approach continually towards coincidence, the line GO will manifestly have for its limit PH, the radius of curvature at P. The limit of the sum of the tangents PG, P′G will be the arc PP′ $= z' - z$. The limit of the sines of the angles POG, P′OG will be the arcs which measure the angles, and that of the sum of the sines will be the measure of the angle POP $=$ NON $= v' - v$. Hence it appears that $r =$ limit of $\dfrac{z'-z}{v'-v}$, and therefore, that

$$r = \frac{dz}{dv} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

This is our first general expression for the radius of curvature. Put $\dfrac{dy}{dx} = p$, $\dfrac{d^2y}{dx^2} = \dfrac{dp}{dx} = q$.

Because (art. 72) $dz = \sqrt{dx^2 + dy^2} = dx\sqrt{1 + \dfrac{dy^2}{dx^2}}$,

therefore $dz = dx\sqrt{1 + p^2}$.

When treating of tangents to curves, we found (art. 65) that $\tan v = \dfrac{dx}{dy}$, therefore, $\tan v = \dfrac{1}{p}$, $\sec v = \dfrac{\sqrt{1+p^2}}{p}$,

and $d(\tan v) = dv \sec^2 v = -\frac{dp}{p^2}$;

hence, $\frac{1+p^2}{p^2}dv = -\frac{qdx}{p^2}$, and $dv = -\frac{qdx}{1+p^2}$.

If now the values of dz and dv be substituted in our first formula for the radius of curvature, there is obtained

$$r = -\frac{1}{q}(1+p^2)^{\frac{3}{2}} = -\frac{(dx^2+dy^2)^{\frac{3}{2}}}{dxd^2y} \ldots\ldots\ldots\ldots(2)$$

This is a second general formula for the radius of curvature.

Let s denote the normal PN. In the right-angled triangle PQN, by trigonometry, $\sin \mathrm{N} = \frac{\mathrm{PQ}}{\mathrm{PN}}$, that is, $\sin v = \frac{y}{s}$; but since

$$\tan v = \frac{dx}{dy} = \frac{1}{p}, \text{ therefore } \frac{y}{s} = \sin v = \frac{1}{\sqrt{1+p^2}},$$

$$\text{and } \sqrt{1+p^2} = \frac{s}{y}, \text{ and } (1+p^2)^{\frac{3}{2}} = \frac{s^3}{y^3}.$$

Referring now to our second formula, we have

$$r = -\frac{s^3}{qy^3} = -\frac{s^3}{y^3}\cdot\frac{dx^2}{d^2y} \ldots\ldots\ldots\ldots\ldots\ldots(3)$$

This is a third formula for the radius of curvature.

If we suppose the nature of the curve (see fig. 14, art. 74) expressed by an equation between $\mathrm{AF} = p$, a perpendicular from a given point in the axis on a tangent PF, and $\mathrm{FAP} = v$, the angle which that perpendicular makes with the axis, and therefore also equal to the angle which the normal PN makes with the axis; then, since $dz = \left(p + \frac{d^2p}{dv^2}\right)dv$; from formula (1) we get also

$$r = p + \frac{d^2p}{dv^2} \ldots\ldots\ldots\ldots\ldots\ldots(4)$$

This is a fourth formula for the radius of curvature.

79. To determine the nature of the evolute EHB, from any point H in the curve draw HK perpendicular to AB, and HI perpendicular to PQ; and assuming A, the origin of the co-ordinates of the involute also as the origin of those of the evolute, let $\mathrm{AK} = \alpha$, $\mathrm{HK} = \beta$; in the triangle PHI, $\mathrm{HI} = \mathrm{PH}\,.\cos \mathrm{H} = r\cos v$, and $\mathrm{PI} = r \sin v$, therefore

$$\alpha = x + r\cos v, \qquad \beta = y - r \sin v.$$

We have found that $\tan v = \frac{1}{p}$, and therefore

$$\cos v = \frac{p}{\sqrt{1+p^2}}, \quad \sin v = \frac{1}{\sqrt{1+p^2}};$$

hence, combining these with the expressions for r, we have

$$\alpha = x - \frac{p}{q}(1+p^2), \quad \beta = y + \frac{1}{q}(1+p^2);$$

or, substituting for p and q the quantities they denote,

$$\alpha = x - \frac{dy}{dx}\cdot\frac{dx^2+dy^2}{d^2y}, \quad \beta = y + \frac{dx^2+dy^2}{d^2y}.$$

In these formulæ, and in the second and third for the radius of curvature, x is regarded as the independent variable, and y as a function of x.

80. From the way in which a curve may be generated by an evolute, we have a method of finding any number of curves which may be rectified, that is, whose length may be assigned in algebraic terms; for PH, the radius of the curvature, is the sum of the straight line CE, and the arc EH of the evolute. Now we can form innumerable curves whose radius of curvature will be known, therefore, corresponding to every curve whose radius of curvature can be found and expressed in algebraic terms, there is a curve which can be exactly rectified.

81. We shall now give examples of the application of the formulæ.

Ex. 1. Let the curve be a parabola, of which AC is the axis: let c denote the parameter, and let $\mathrm{AQ} = x$, and $\mathrm{PQ} = y$, be the co-ordinates of P, any point in the curve. Let CH be the evolute, and let $\mathrm{AK} = \alpha$, $\mathrm{HK} = \beta$, be the co-ordinates of H, the centre of curvature at P, the radius of curvature being $\mathrm{PH} = r$.

By the nature of the curve, $y^2 = cx$, therefore,

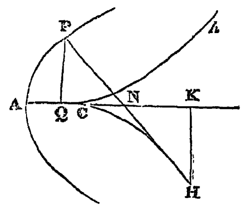
$$\frac{dy}{dx} = p = \frac{c}{2y};\ 1+p^2 = \frac{c^2+4y^2}{4y^2} = \frac{c+4x}{4x};$$

$$\frac{d^2y}{dx^2} = \frac{dp}{dx} = q = -\frac{c}{2}\frac{dy}{dx}\cdot\frac{1}{y^2} = -\frac{c^2}{4y^3};$$

$$r = -\frac{(1+p^2)^{\frac{3}{2}}}{q} = \frac{(c^2+4y^2)^{\frac{3}{2}}}{2c^2} = \frac{(c^2+4cx)^{\frac{3}{2}}}{2c^2}$$

$$= \tfrac{1}{2}\sqrt{\frac{(c+4x)^3}{c}}.$$

Fig. 16.



This is the expression for the radius of curvature by formula (2). If we put the normal $\mathrm{PN} = s$, we have, by formula (3) (art. 78),

$$r = -\frac{s^3}{qy^3} = \frac{4s^3}{c^2}\,. = \frac{s^3}{(\frac{1}{2}c)^2} = \frac{(\text{normal})^3}{(\text{semipar.})^2}.$$

Next, to find the evolute, we have

$$\alpha = x - \frac{p}{q}(1+p^2) = x + \frac{4x+c}{2} = 3x + \tfrac{1}{2}c;$$

$$\beta = y + \frac{1+p^2}{q} = y - \frac{c^2+4y^2}{c^2}y = \frac{-4y^3}{c^2}.$$

Hence $x = \frac{1}{3}(\alpha - \frac{1}{2}c)$, $y = -\left(\frac{c^2\beta}{4}\right)^{\frac{1}{3}}$;

and since, by the nature of the parabola, $cx = y^2$; therefore the equation of the evolute is

$$\beta^2 = \frac{16}{27c^2}\left(\alpha - \frac{c}{2}\right)^3;$$

Take $\mathrm{AC} = \frac{1}{2}c$, then C is a given point; and $\mathrm{CK} = \alpha - \frac{1}{2}c$. Put $\mathrm{CK} = x'$; $\mathrm{HK} = \beta = -y'$, and the equation of the involute becomes

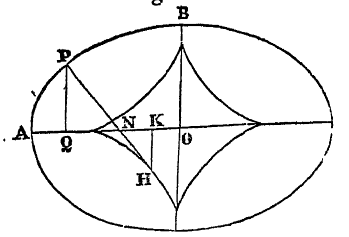
$$y'^2 = \frac{16}{27c}x'^3.$$

Hence it appears that the evolute is the semicubical parabola. This is the first curve that was rectified by the infinitesimal calculus.

Ex. 2. Let the curve be an ellipse, of which $\mathrm{OA} = a$ is the semitransverse axis, and $\mathrm{OB} = b$ the semiconjugate. Let $e = \sqrt{a^2 - b^2}$ be the eccentricity, and, assuming the centre as the origin of co-ordinates, let $\mathrm{OQ} = x$, $\mathrm{PQ} = y$, HP, the radius of curvature at P, $= r$.

The equation of the curve is $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$; or $b^2x^2 + a^2y^2 = a^2b^2$: Hence

Fig. 17.



$$\frac{dy}{dx}=p=-\frac{b^2x}{a^2y};$$

$$1+p^2=\frac{b^2}{a^2}\cdot\frac{a^4-(a^2-b^2)\,x^2}{a^2y^2}=\frac{b^2}{a^2}\cdot\frac{a^4-e^2x^2}{a^2y^2}$$

$$=\frac{b^4+(a^2-b^2)\,y^2}{a^2y^2}=\frac{b^4+e^2y^2}{a^2y^2}.$$

$$\frac{d^2y}{dx^2}=\frac{dp}{dx}=q=-\frac{b^2}{a^2y}+\frac{b^2x}{a^2y^2}\cdot\frac{dy}{dx}=-\frac{b^4}{a^2y^3};$$

$$\frac{(1+p^2)^{\frac{3}{2}}}{q}=\frac{-1}{a^4b}\,(a^4-e^2x^2)^{\frac{3}{2}}=\frac{-1}{ab^4}\,(b^4-e^2y^2)^{\frac{3}{2}}.$$

Hence the radius of curvature

$$r=\frac{1}{a^4b}\,(a^4-e^2x^2)^{\frac{3}{2}}=\frac{1}{ab^4}\,(b^4+e^2y^2)^{\frac{3}{2}}$$

$$=\frac{1}{a^4b^4}\,(a^4y^2+b^4x^2)^{\frac{3}{2}}.$$

The formula $r=-\frac{s^3}{y^3q}$ (where $s=$ the normal PN) gives this other value,

$$r=\frac{a^2}{b^4}\,s^3.$$

Now $\frac{b^2}{a}$ is half the parameter of the transverse axis; therefore $r=\frac{(\text{normal})^3}{(\frac{1}{2}\text{ parameter})^2}$ ....(2)

To find the equation of the evolute, let H be any point in the curve; $OK=\alpha$, and $HK=\beta$, the co-ordinates. The values of p, $1+p^2$, and q, being substituted in the formula (art. 79), we have

$$\alpha=x-\frac{b^2x}{a^2y}\cdot\frac{a^2y^3}{b^4}\cdot\frac{b^2}{a^2}\cdot\frac{a^4-ex^2}{a^2y^2}=\frac{e^2x^3}{a^4}:$$

$$\beta=y-\frac{a^2y^3}{b^4}\cdot\frac{b^4-e^2y^2}{a^2y^2}=\frac{e^2y^3}{b^4}.$$

Let us exchange α and β for x' and y', and we have

$$\frac{x^2}{a^2}=\left(\frac{ax'}{e^2}\right)^{\frac{2}{3}};\quad \frac{y^2}{b^2}=\left(\frac{by'}{e^2}\right)^{\frac{2}{3}}.$$

Observing now that in the ellipse $\frac{x^2}{a^2}+\frac{y^2}{b^2}=1$, we have for the equation of the evolute

$$\left(\frac{ax'}{e^2}\right)^{\frac{2}{3}}+\left(\frac{by'}{e^2}\right)^{\frac{2}{3}}=1;\ \text{or } (ax')^{\frac{2}{3}}+(by')^{\frac{2}{3}}=(a^2-b^2)^{\frac{2}{3}}.$$

The form of this equation is remarkable from its analogy to that of the ellipse itself. The curve has the form shown in figure 17.

Ex. 3. Let the curve be the cycloid; of which let AA′ be the base, BC the axis, BDC a circle whose diameter is BC. From P any point in the curve, draw PDE perpendicular to the axis, meeting the circle in D; draw PQ perpendicular to the base, and let PH be the radius of curvature.

Since all cycloids are similar figures, we may make the radius of the generating circle $=1$; let $CQ=PE=x$, $PQ=CE=y$, the arc $BD=v$.

By the nature of the cycloid (art. 66, ex. 4),

$$x=v+\sin v,\quad y=1-\cos v,$$

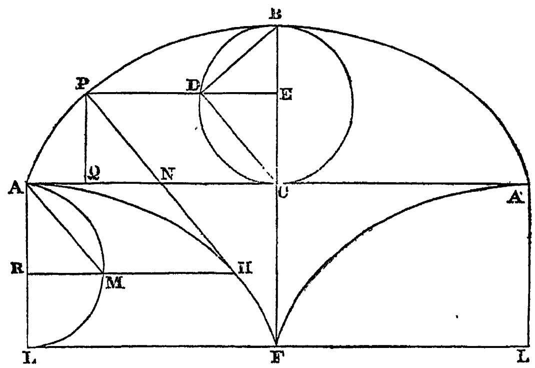
therefore $dx=dv\,(1+\cos v)$, $dy=dv\sin v$,

$$\frac{dy}{dx}=p=\frac{\sin v}{1+\cos v};\ 1+p^2=\frac{2}{1+\cos v},\ dp=\frac{dv}{1+\cos v};$$

$$\frac{d^2y}{dx^2}=\frac{dp}{dx}=q=\frac{1}{(1+\cos v)^2},$$

Hence r, the rad. of cur. $=-\frac{(1+p^2)^{\frac{3}{2}}}{q}=\sqrt{8\,(1+\cos v)}$.

Fig. 18.



Draw the chord CD, and because $1+\cos v=2\cos^2\frac{1}{2}v$ (ALGEBRA, 249) $=2\sin^2\frac{1}{2}$ arc CD $=\frac{1}{2}$ chord^2 CD.

Therefore, $PH=r=2$ chord CD.

It was shown (art. 66) that a tangent at P is parallel to BD, the chord of the supplement of CD; therefore PH, which is perpendicular to the tangent, is parallel to the chord CD; it is therefore determined in position and magnitude for any given point in the curve.

The evolute AHF may be found by the general formula (art. 79), or otherwise from the expression for PH, the radius of curvature, thus:

Draw AL perpendicular to AC, and equal to BC, but on the opposite side of AC; describe the semicircle AML, and draw HMR perpendicular to AL, cutting the semicircle in M; let PH meet AC in N.

Because CA $=$ semicircumference CDB, and CN $=$ DP $=$ arc BD, therefore AN $=$ arc CD. But because PH $=$ 2CD $=$ 2PN; and therefore PN $=$ NH; the parallels PE, HR are equally distant from CA; and hence CE $=$ RA, and arc CD $=$ arc AM and chord CD $=$ chord AM, also angle DCA $=$ angle CAM. Now CD $=$ PN $=$ NH: therefore AM $=$ NH; but AM is parallel to NH; therefore MH $=$ AN $=$ arc CD $=$ arc AM; and HR $=$ arc AM $+$ sin MR; thus it appears that H is a point in a semicycloid having the same base as the cycloid ABA′. Indeed LAF is just the semicycloidal space CBA′ transferred to the position AHF, the point B being placed at A, and A′ at F. If the other semicycloidal space AB be transferred to the position FA′L′, the arc APB in the position FA′ will form another branch of the evolute, exactly similar to FA, but turned the contrary way.

From what has been found it appears, that if the semicycloids FLA, FL′A′ were placed in a vertical plane, with the point F uppermost, and the semi-bases FL, FL′ in a horizontal line; and if a weight were suspended from F by a thread equal in length to FB, and made to vibrate in that plane, like a pendulum; the weight would manifestly vibrate in an arc of a cycloid. This elegant property of the curve was discovered by Huygens, who also found that the vibrations would be isochronal, that is, performed

in equal times. This is an important proposition in dynamics.

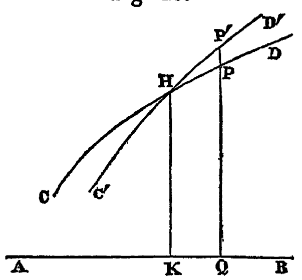
Contact of Curves.

82. The ancient geometers paid particular attention to the contact of straight lines, with the few curve lines which they considered. Apollonius even touched on the contact of circles and the conic sections; for he treated of the shortest line that can be drawn from a given point in the axis to the curve. It is only, however, since the invention of the differential calculus that this branch of geometry has been carried to any considerable extent.

83. The curvature of a circle being the same throughout, it serves as the means of comparing the curvature in different points of a curve. It is, however, easy to understand, that in like manner we might consider the nature of the contact of a parabola, or a curve of any kind whatever, with a proposed curve.

Let $y=f(x)$ and $v=F(x)$ be the equations of two curves CPD, C′P′D′, which have a common axis AB, and the same point A for the origin of co-ordinates. Let x

Fig. 19.



be a common absciss, and y the corresponding ordinate of any point in the curve CD; also v, the like ordinate in the curve C′D′. Suppose now that when x becomes $x+h$, y becomes y', and v becomes v'; by Taylor's theorem,

$$y'=y+\frac{dy}{dx}h+\frac{d^2y}{dx^2}\frac{h^2}{1\,.\,2}+\text{\&c.}$$

$$v'=v+\frac{dv}{dx}h+\frac{d^2v}{dx^2}\frac{h^2}{1.2}+\text{\&c.}$$

Suppose now the curves to have a common point H, at which $y=v$; then, *If the curves be such that* $\frac{dy}{dx}=\frac{dv}{dx}$, *their contact at* P *will be of such a nature, that no third curve can pass between them at that point, unless it has a like property.*

Let HK $=y=v$, KQ $=h$, PQ $=y'$, P′Q $=v'$. Also, let $u=$ HK be the ordinate of a third curve that passes through H, and u' its value, corresponding to AQ $=x+h$, then

$$u'=u+\frac{du}{dx}h+\frac{d^2u}{dx^2}\frac{h^2}{1\,.\,2}+\text{\&c.}$$

We are to prove it to be impossible for the third curve, in leaving the point H, to pass between the arcs HP and HP′, unless $\frac{du}{dx}=\frac{dy}{dx}=\frac{dv}{dx}$. For suppose it possible, then, because in general

$$PP'=y'-v'=y-v+\left(\frac{dy}{dx}-\frac{dv}{dx}\right)h+\left(\frac{d^2y}{dx^2}-\frac{d^2v}{dx^2}\right)\frac{h^2}{2}+\text{\&c.}$$

and, because at the point H, $y=v$; and, in this particular case, $\frac{dy}{dx}=\frac{dv}{dx}$, we have

$$y'-v'=\left(\frac{d^2y}{dx^2}-\frac{d^2v}{dx^2}\right)\frac{h^2}{2}+\left(\frac{d^3y}{dx^3}-\frac{d^3v}{dx^3}\right)\frac{h^3}{6}+\text{\&c.}$$

This is the general expression for P′P′, the difference between the ordinates of the curves CD, C′D′, whatever be the magnitude of KQ $=h$.

In like manner, the difference between y', the ordinate of the first curve, and u', that of the third, will be generally expressed by

$$y'-u'=y-u+\left(\frac{dy}{dx}-\frac{du}{dx}\right)h+\left(\frac{d^2u}{dx^2}-\frac{d^2u}{dx^2}\right)\frac{h^2}{2}+\text{\&c.}$$

which, on the hypothesis that $y=u$, becomes

$$y'-u'=\left(\frac{dy}{dx}-\frac{du}{dx}\right)h+\left(\frac{d^2y}{dx^2}-\frac{d^2u}{dx^2}\right)\frac{h^2}{2}+\text{\&c.}$$

Now, if it were possible that the third curve, in leaving the common point H, could pass between the other two, we should, to a certain extent from the point H, have $y'-v'$ greater than $y'-u'$, that is, after dividing the expressions for $y'-v'$ and $y'-u'$ by h,

$$\left(\frac{d^2y}{dx^2}-\frac{d^2v}{dx^2}\right)\frac{h}{2}+\left(\frac{d^3y}{dx^3}-\frac{d^3v}{dx^3}\right)\frac{h^2}{6}+\text{\&c.}$$
$$>\frac{dy}{dx}-\frac{du}{dx}+\left(\frac{d^2y}{dx^2}-\frac{d^2u}{dx^2}\right)\frac{h}{2}+\text{\&c.}$$

And this equation ought to hold true, however small the line KQ $=h$ be taken. But h may be taken so small, that all the terms in the expression for $y'-v'$ shall be less than any assignable quantity, while those of $y'-u'$ continually approach to $\frac{dy}{dx}-\frac{du}{dx}$ as a limit, which by hypothesis is not equal to zero. Now these two conclusions are incompatible with each other; therefore it is impossible that the third curve can pass through the point P between the other two, when $\frac{dy}{dx}$ is not equal to $\frac{du}{dx}$.

If, however, $\frac{dy}{dx}=\frac{du}{dx}$, then the third curve may pass between the other two; for it will only be necessary that

$$\frac{d^2y}{dx^2}-\frac{d^2v}{dx^2}>\frac{d^2y}{dx^2}-\frac{d^2u}{dx^2},\ \text{that is,}\ \frac{d^2u}{dx^2}>\frac{d^2v}{dx^2},$$

which is evidently possible.

84. Again, if there be two curves whose equations are $y=f(x)$, $v=F(x)$, and which have a common ordinate $y=v$, and if they be such, that

$$\frac{dy}{dx}=\frac{dv}{dx},\qquad \frac{d^2y}{dx^2}=\frac{d^2v}{dx^2};$$

then no third curve of which the equation is $u=\varphi(x)$, and which has a common ordinate with the other two, can pass between them, unless at the same time

$$\frac{dy}{dx}=\frac{du}{dx},\qquad \frac{d^2y}{dx^2}=\frac{d^2u}{dx^2}.$$

This proposition is proved exactly in the same way as that in last article, by means of Taylor's theorem. These are particular cases of a general proposition relating to the contact of curves which may be stated thus: If two curves have a common absciss and ordinate, and if the differential co-efficients of the first order of the ordinates be equal, no third curve passing through their intersection can go between them, unless the differential co-efficient of its ordinate, corresponding to the same absciss, be equal to the differential co-efficients of their ordinates. And if, besides their first differential co-efficients, their second differential co-efficients be equal, then no third curve passing through their intersection can go between them, unless the first and second differential co-efficients of its ordinate be equal to the first and second differential co-efficients of the two curves, and so on to differential co-efficients of all orders.

Direct Method.

In fact, the two curves meet only in the point in which their ordinates are the same, and the equality of the differential co-efficients merely indicates that no other curve in which the same equality does not take place can pass between them.

From what has been shown, it appears that the contacts of curve lines may be distinguished into different orders. The degree of contact in which the ordinates and also the first differential co-efficients are equal, may be called a *Contact of the first order*; when, in addition to these, the second differential co-efficients are equal, it is a *Contact of the second order*; and so on.

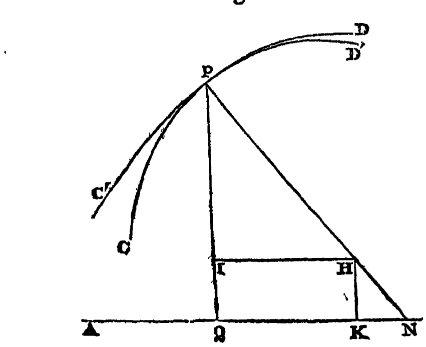
85. In illustration of this theory of contacts, let us consider the nature of the contact of any curve HPK (see fig. 6), with a straight line PT. Let A be the common origin of the co-ordinates. In the curve, let $AB = x$, $PB = y$. Its nature will be expressed by an equation $y = f(x)$. In the straight line, let $TA = c$, $AB = x$, $PB = v$, angle $PTB = \alpha$; the equation of the straight line is $v = (c + x)\tan\alpha$. The hypothesis that the curve and straight line have a common point, gives $y = v$; and the equation of the straight line, considering that c and α must be regarded as constants, gives $\frac{dv}{dx} = \tan\alpha$; now, by our theory, $\frac{dy}{dx} = \frac{dv}{dx}$, therefore $\frac{dy}{dx} = \tan\alpha$. This result coincides with what was found in art. 65; and it gives the sub-tangent

$$BT = \frac{y}{\tan\alpha} = \frac{dx}{dy}y.$$

It is impossible that any straight line can pass between the straight line PT and the curve; for, if possible, let the straight line PS pass between them, and meet the axis in S. Put $AS = c'$, $AB = x$, $PB = u$, the angle $PSB = \alpha'$. The equation of the straight line PS is $u = (c' + x)\tan\alpha'$; and hence $\frac{du}{dx} = \tan\alpha'$. Now, that the line PS may pass between PT and the curve, we should have $\frac{du}{dx} = \frac{dv}{dx} = \frac{dy}{dx}$ (art. 83); therefore, $\tan\alpha' = \tan\alpha$, and $\alpha' = \alpha$; thus it appears that the lines PS, PT must coincide; therefore the straight line PT is a tangent to the curve, in the strictest sense.

86. Let us next consider the nature of the contact of a circle and any curve. Let CPD be the curve, and C′PD′ a circle referred to the same axis AK, in which A is the common origin of the co-ordinates. In the curve CPD let $AQ = x$, $PQ = y$. Let H be the centre of the circle; draw the radius PH, and produce it to meet the axis in N, and draw HI, HK perpendicular to PQ and AQ. Put $AQ = x$, $PQ = v$, these being co-ordinates of P any point in the circumference of the circle; and put $AK = \alpha$, $HK = \beta$, the co-ordinates of its centre; and $PH = r$ its radius.

Fig. 20.



The equation of the curve CPD may be expressed generally by $y = f(x)$. And, since $IH = \alpha - x$, $PI = v - \beta$, and $PH = r$, the equation of the circle will be

$$(\alpha - x)^2 + (v - \beta)^2 = r^2 \quad\text{.................(1)}$$

A contact of the first degree requires that $\frac{dy}{dx} = \frac{dv}{dx}$. Now, observing that α, β, and r must be considered as constants, we have $\frac{dv}{dx} = \frac{\alpha - x}{v - \beta}$, hence and because $y = v$,

$$\frac{dy}{dx} = \frac{\alpha - x}{y - \beta} \quad\text{.....................(2)}$$

The second side of this formula expresses the trigonometrical tangent of the angle HPI. Hence (art. 65) the line PN is a normal to the curve at P, and the circle and curve have a common tangent at that point. By a second differentiation

$$\frac{d^2v}{dx^2} = -\frac{1}{v - \beta} - \frac{\alpha - x}{(v - \beta)^2}\cdot\frac{dv}{dx} = -\frac{(\alpha - x)^2 + (v - \beta)^2}{(v - \beta)^3}.$$

Now, that the circle and curve may have a contact of the second degree of closeness, it is necessary that $\frac{d^2v}{dx^2} = \frac{d^2y}{dx^2}$, therefore, observing that $v = y$, and that $(\alpha - x)^2 + (v - \beta)^2 = r^2$, we have

$$\frac{d^2y}{dx^2} = \frac{-r^2}{(y - \beta)^3} \quad\text{.......................(3)}$$

The three equations (1), (2), (3) serve to determine r, the radius of the circle, and α, β the co-ordinates of its centre. From the first and second we get

$$\alpha - x = \frac{r\,dy}{(dx^2 + dy^2)^{\frac{1}{2}}};\quad y - \beta = \frac{r\,dx}{(dx^2 + dy^2)^{\frac{1}{2}}};$$

and from these, and equation (3), we get

$$r = -\frac{(dx^2 + dy^2)^{\frac{3}{2}}}{dx\,d^2y};$$

$$\alpha = x - \frac{dy}{dx}\cdot\frac{dx^2 + dy^2}{d^2y};\quad \beta = y + \frac{dx^2 + dy^2}{d^2y}.$$

These expressions for α, β, and r determine the position and magnitude of the circle; they are manifestly identical with the radius of the circle of equal curvature, and the co-ordinates of its centre formerly found (art. 78 and 79). Hence we conclude, that the circle of equal curvature with a curve in any point, determined by the theory of evolutes, is identical with a circle, having with the curve a contact of the second order.

And since it appears that only one circle can have with a curve a contact of the second order, and that no circle can pass between that circle and the curve, therefore the same must be true of the circle of equal curvature, found by the theory of evolutes.

87. From what has been shown in regard to the degrees of contact of a straight line and circle with a curve, it appears that these depend on the number of constants which enter into the equation of the touching line. The equation of a straight line contains two constants, and it admits of one order of contact only. The equation of a circle has three constants, and it admits of a contact of the second order. It is easy to see that the number of differential co-efficients that can be made equal in the two curves will always be one less than the number of constants in the touching curve. The equation of a parabola is $y = \alpha + \beta x + \gamma x^2$. This and the differential equations which may be deduced from it serve to determine the three constants α, β, γ, and thence the parabola of equal curvature; but since there are only two differential co-efficients, the parabola can have a contact of the first and

also of the second order with any curve, but no higher order of contact. A cubic parabola, whose equation is $y = \alpha + \beta x + \lambda x^2 + \delta x^3$, may, however, have a contact of the third order, because it involves four constants, and so on.

Development and Differentiation of Functions containing two Variables.

88. Let u be a function of two independent variables, x and y; for example, $u = ax^2 + bxy + cy^2$, and in general $u = f(x, y)$. Suppose now that x changes its value, and becomes $x + h$, and that y becomes $y + k$, so that u' being the new value of the function, $u' = f(x+h, y+k)$. It is proposed to expand u' into a series of terms proceeding by the integer powers of h and k. In particular cases the method of proceeding is obvious; a general formula may be found by Taylor's theorem as follows.

It is easy to see that the result will be the same whether we substitute at once $x + h$ for x, and $y + k$ for y, in the function u, and then expand it; or, otherwise, first substitute $x + h$, then expand the function, according to the powers of h, and in this first result put $y + k$ for y, and afterwards expand it into terms proceeding by the powers of k; or we may reverse this process, beginning with the expansion according to the powers of k, and ending with that proceeding by the powers of h.

Resuming the function $u = f(x, y)$; when x becomes $x + h$, we have by Taylor's theorem $f(x + h, y) =$

$$u + \frac{du}{dx}h + \frac{d^2u}{dx^2}\frac{h^2}{1.2} + \frac{d^3u}{dx^3}\frac{h^3}{1.2.3} + \text{\&c.}$$

the differentials being taken upon the supposition that x is variable, and y a constant. And in this series y is contained only in the function u, and the differential co-efficients $\frac{du}{dx}, \frac{d^2u}{dx^2}$, &c.

Suppose now that y becomes $y + k$, then, in the series, the function u becomes

$$u + \frac{du}{dy}k + \frac{d^2u}{dy^2}\frac{k^2}{1.2} + \frac{d^3u}{dy^3}\frac{k^3}{1.2.3} + \text{\&c.};$$

the function $\frac{du}{dx}$ becomes

$$\frac{du}{dx} + \frac{d\frac{du}{dx}}{dy}k + \frac{d^2\frac{du}{dx}}{dy^2}\frac{k^2}{1.2} + \frac{d^3\frac{du}{dx}}{dy^3}\frac{k^3}{1.2.3} + \text{\&c.};$$

the function $\frac{d^2u}{dx^2}$ becomes

$$\frac{d^2u}{dx^2} + \frac{d\frac{d^2u}{dx^2}}{dy}k + \frac{d^2\frac{d^2u}{dx^2}}{dy^2}\frac{k^2}{1.2} + \frac{d^3\frac{d^2u}{dx^2}}{dy^3}\frac{k^3}{1.2.3} + \text{\&c.};$$

the function $\frac{d^3u}{dx^3}$ becomes

$$\frac{d^3u}{dx^3} + \frac{d\frac{d^3u}{dx^3}}{dy}k + \frac{d^2\frac{d^3u}{dx^3}}{dy^2}\frac{k^2}{1.2} + \frac{d^3\frac{d^3u}{dx^3}}{dy^3}\frac{k^3}{1.2.3} + \text{\&c.};$$

and in the differentiation of the functions $u, \frac{du}{dx}, \frac{d^2u}{dx^2}$, &c., y is taken as the variable, and x as a constant. By making the proper substitutions, we have $f(x + h, y + k)$ expressed by the series

$$u + \frac{du}{dy}k + \frac{d^2u}{dy^2}\frac{k^2}{1.2} + \text{\&c.}$$

$$+ \frac{du}{dx}h + \frac{d\frac{du}{dx}}{dy}hk + \text{\&c.}$$

$$+ \frac{d^2u}{dx^2}\frac{h^2}{1.2} + \text{\&c.}$$

$$+ \text{\&c.}$$

If the substitutions of $x + h$ for x, and $y + k$ for y, had been made in an inverse order, we would have had $f(y + k, x + h)$ equal to

$$u + \frac{du}{dx}h + \frac{d^2u}{dx^2}\frac{h^2}{1\cdot2} + \text{\&c.}$$

$$+ \frac{du}{dy}k + \frac{d\frac{du}{dy}}{dx}hk + \text{\&c.}$$

$$+ \frac{d^2u}{dy^2}\frac{k^2}{1\cdot2} + \text{\&c.}$$

The order in which the substitutions are made being arbitrary, the two developments of $f(x + h, y + k)$ must be identical, consequently the terms containing the same products of h and k must be equal. Thus, passing over the terms which are the same, we have

$$\frac{d\frac{du}{dx}}{dy} = \frac{d\frac{du}{dy}}{dx}.$$

89. This formula proves an important theorem in the calculus, namely, if a function u of two independent variables x and y be twice differentiated, first, on the hypothesis that x is variable and y constant, and then the result on the supposition that y is variable and x constant. And again, if the order of the differentiations be reversed, that is, if y be made variable and x constant, and then x variable and y constant, the final result either way will be the very same.

The symbol $\frac{d\frac{du}{dx}}{dy}$, which expresses the result of two differentiations performed on u, a function of two variables x and y (the first on the supposition that x is variable and y constant, and the second on the reverse supposition), may conveniently be simplified into $\frac{d^2u}{dxdy}$. By this notation the theorem just enunciated in words will be expressed in symbols thus:

$$\frac{d^2u}{dxdy} = \frac{d^2u}{dydx}.$$

By continuing the two developments a term farther, we would have arrived at the conclusion that (having regard to the notation just premised),

$$\frac{d^3u}{dxdydx} = \frac{d^3u}{dx^2dy} = \frac{d^3u}{dydx^2};$$

$$\text{and that } \frac{d^3u}{dxdy^2} = \frac{d^3u}{dy^2dx}, \text{ \&c.}$$

Suppose, for example, that $u = x^3y^5$, then

$$\frac{du}{dx} = 3x^2y^5, \qquad \frac{du}{dy} = 5x^3y^4,$$

$$\frac{d^2u}{dxdy} = 15x^2y^4, \quad \frac{du}{dydx} = 15x^2y^4,$$

$$\frac{d^3u}{dx^2dy} = 30xy^4, \quad \frac{d^3u}{dydx^2} = 30xy^4.$$

Adopting now the abbreviated notation, when $u = f(x, y)$, we have $f(x + h, y + k) =$

$$u + \frac{du}{dx}h + \frac{d^2u}{dx^2}\frac{h^2}{2} + \frac{d^3u}{dx^3}\frac{h^3}{2.3} + \text{\&c.}$$

$$+ \frac{du}{dy}k + \frac{d^2u}{dydx}hk + \frac{d^3u}{dydx^2}\frac{h^2k}{2} + \text{\&c.}$$

$$+ \frac{d^2u}{dy^2}\frac{k^2}{2} + \frac{d^3u}{dy^2dx}\frac{hk^2}{2} + \text{\&c.}$$

$$+ \frac{d^3u}{dy^3}\frac{k^3}{2.3} + \text{\&c.}$$

This is the complete development of the function u.

90. Supposing u to be any function of x, and that x becomes $x+h$, by which u becomes $u+ph+qh^2+$&c., or (considering h as the *differential* of x) $u+pdx+qdx^2+$ &c. We have defined the *differential* of u to be the term pdx, viz. that which contains the simple power of h or dx, and called the function p, the *differential co-efficient,* representing it by $\frac{du}{dx}$. We may now extend these definitions to $f(x, y)$, a function of two variables, and changing h into dx and k into dy in the development of the function, we shall have

$$df(x, y) = du = \frac{du}{dx}dx + \frac{du}{dy}dy.$$

From this it appears that the *complete* differential of a function of two variables consists of two parts, viz. $\frac{du}{dx}dx$, or the differential taken on the supposition that x alone is variable, and $\frac{du}{dy}dy$, or the differential taken when y only is variable.

We may also apply to functions of two variables the rules which have been given (art. 10–23) for those which depend only on one; and for this purpose *we must differentiate the function first with respect to one of its variables, and then with respect to another; and take the sum of the results for the complete differential required.* By this rule

$$d(x+y) = dx + dy$$
$$d(xy) = ydx + xdy,$$
$$d\left(\frac{x}{y}\right) = \frac{dx}{y} - \frac{xdy}{y^2} = \frac{ydx - xdy}{y^2}.$$

Again, let $u = x^my^n$, we have

$$\frac{du}{dx}dx = mx^{m-1}y^ndx, \quad \frac{du}{dy}dy = nx^my^{n-1}dy,$$

$$du = \frac{du}{dx}dx + \frac{du}{dy}dy = x^{m-1}y^{n-1}(mydx + nxdy).$$

91. The manner in which the differentials of functions which depend on more than one variable are written, gives rise to some important remarks. The expression $\frac{du}{dx}dx$ must not be confounded with du, which it might be if u contained only the variable x; the symbol $\frac{du}{dx}$ has in this case a particular meaning, and denotes the differential co-efficient taken on the hypothesis of x only being variable; or it is the quotient of the first term of the development of the difference taken on that supposition divided by the increment dx; and $\frac{du}{dy}dy$ signifies the same with respect to y.

The quantities $\frac{du}{dx}, \frac{du}{dy}$ are commonly called *partial differences* of the first order of the function u, and generally $\frac{d^{m+n}u}{dx^mdy^n}$ represents one of those of the order $m+n$, which arises by differentiating m times in respect of x, and n times in respect of y.

A function of a single variable has only one differential co-efficient of any order; but a function of two variables has two differential co-efficients for the first order, three for the second, &c. These may be deduced from the two first, beginning with

$$du = \frac{du}{dx}dx + \frac{du}{dy}dy;$$

then, taking the differentials of $\frac{du}{dx}$ and $\frac{du}{dy}$, which must be treated as functions of two variables, we have

$$d\frac{du}{dx} = \frac{d^2u}{dx^2}dx + \frac{d^2u}{dydx}dy,$$

$$d\frac{du}{dy} = \frac{d^2u}{dxdy}dx + \frac{d^2u}{dy^2}dy;$$

and since the second differential is nothing more than the differential of the first,

$$d^2u = \frac{d^2u}{dx^2}dx^2 + 2\frac{d^2u}{dxdy}dxdy + \frac{d^2u}{dy^2}dy^2.$$

Here dx and dy are considered as constant quantities, and the differential co-efficients whose denominators contain only the products of dx and dy differently arranged, are considered as identical. By a repetition of this process, an expression may be found for the third differential co-efficient of the function u, and so on to any differential.

92. What has been explained in respect of a function of two independent variables, will apply to a function of any number; thus, if $u = f(t, x, y, z)$, then,

$$du = \frac{du}{dt}dt + \frac{du}{dx}dx + \frac{du}{dy}dy + \frac{du}{dz}dz,$$

where the symbols

$$\frac{du}{dt}, \frac{du}{dx}, \frac{au}{dy}, \frac{du}{dz},$$

denote the differential co-efficients of the function u taken on the supposition that t or x or y or z alone varies.

This notation owes its origin to Fontaine. Euler feared that the differential co-efficient $\frac{du}{dx}$ might be confounded with the ratio of the complete differential du to the differential dx, which is equivalent to

$$\frac{\frac{du}{dt}dt + \frac{du}{dx}dx + \frac{du}{dy}dy + \frac{dz}{dz}dz}{dx},$$

he therefore denoted this ratio by $\frac{du}{dx}$, whilst he expresses the differential co-efficient found by supposing x alone variable by $\left(\frac{du}{dx}\right)$. The nature of the subject, however, in general shows which of the two is intended, and renders this distinction superfluous.

Of Changing the Independent Variable.

93. Supposing y to be any function of x, we have estimated every change in the magnitude y by that of the value of x, which has been supposed to vary in any way whatever. It is, however, sometimes convenient to reverse the hypothesis, and consider x as a function of y. We are now to investigate general rules, by which we may pass from the differentials of y, regarded as a function of x, to those of x considered as a function of y.

Let $y = f(x)$, and let us suppose that when x becomes $x+h$, y becomes $y+k$. By Taylor's theorem,

$$k = \frac{dy}{dx}h + \frac{d^2y}{dx^2}\frac{h^2}{2} + \frac{d^3y}{dx^3}\frac{h^3}{2.3} + \text{\&c.} \quad \text{(1)}$$

On the reverse hypothesis, supposing $x = \mathrm{F}(y)$ a function of y, then, similarly,

$$h=\frac{dx}{dy}k+\frac{d^2x}{dy^2}\frac{k^2}{2}+\frac{d^3x}{dy^3}\frac{k^3}{2\,.\,3}+\text{\&c.}\ldots\ldots\ldots\ldots(2)$$

Let the value of k, as given by the first equation, be substituted in the second; and, in order to abridge, let us put $\frac{dy}{dx}=y'$, $\frac{d^2y}{dx^2}=y''$, &c.

also $\frac{dx}{dy}=x'$, $\frac{d^2x}{dy^2}=x''$, &c.; then we have

$$h = x'\left(y'h+y''\frac{h^2}{2}+y'''\frac{h^3}{2\,.\,3}+\text{\&c.}\right)$$
$$+\frac{x''}{2}\left(y'h+y''\frac{h^2}{2}+y'''\frac{h^3}{2\,.\,3}+\text{\&c.}\right)^2+\text{\&c.}$$

Hence, by actually involving the series to the second, third, powers, &c. and bringing into one term like powers of h, we find

$$0=(x'y'-1)\,h+(x'y''+x''y'^2)\frac{h^2}{2}$$
$$+(x'y'''+3x''y'y''+x'''y')\frac{h^3}{3}+\text{\&c.}$$

Now, that this equation may be satisfied, the co-efficients of the powers of h must be each $=0$; thus,

$$x'y'-1=0,\quad x'y''+x''y'^2=0,$$
$$x'y'''+3x''y'y''+x'''y'=0,\ \text{\&c.}$$

These equations give us

$$y'=\frac{1}{x'},\quad y''=-\frac{x''}{x'^3},\quad y'''=\frac{3x''^2}{x'^5}-\frac{x'''}{x'^4},$$
$$y^{\mathrm{IV}}=\frac{15x''^3}{x'^7}+\frac{10x''x'''}{x'^6}-\frac{x^{\mathrm{IV}}}{x'^5},\ \text{\&c.}$$

Reversely, we have

$$x'=\frac{1}{y'},\quad x''=-\frac{y''}{y'^3},\quad x'''=\frac{3y''^2}{y'^5}-\frac{y'''}{y'^4},$$
$$x^{\mathrm{IV}}=\frac{15y''^3}{y'^7}+\frac{10y''y'''}{y'^6}-\frac{y^{\mathrm{IV}}}{y'^5},\ \text{\&c.}$$

As an application of these formulæ, we may transform the expression for the radius of curvature found (art. 78), on the hypothesis that y is a function of x, into another in which x is a function of y. Employing the notation of last article,

$$r=-\frac{(1+y'^2)^{\frac{3}{2}}}{y''}.$$

Now by the formulæ $y'=\frac{1}{x'}$, and $y''=-\frac{x''}{x'^3}$: this substitution being made, we obtain

$$r=\frac{(x'^2+1)^{\frac{3}{2}}}{x''}=\frac{(dx^2+dy^2)^{\frac{3}{2}}}{dyd^2x}.$$

94. Instead of supposing that one of the two variables x, y, is a function of the other, it is sometimes convenient to regard both as functions of a third quantity. Thus, in geometry, supposing x and y to be the co-ordinates of a curve, we may consider the one as a function of the other; or we may consider both as functions of the angle which a tangent makes with the axis, which angle is then the independent variable. Or x and y denoting the co-ordinates of the path of a projectile, both may be considered as functions of t, the time of the motion.

Suppose that when t becomes $t+i$, x becomes $x+h$, and that y becomes $y+k$; to abridge, put x', x'', &c. for $\frac{dx}{dt}$, $\frac{d^2x}{dt^2}$, &c.; also y', y'', &c. for $\frac{dy}{dt}$, $\frac{d^2y}{dt^2}$, &c. and (y'), (y''), &c. for $\frac{dy}{dx}$, $\frac{d^2y}{dx^2}$, &c.

By Taylor's theorem,

$$y=f(x)\text{ gives }k=(y')\,h+(y'')\frac{h^2}{2}+\text{\&c.}\ldots\ldots(1)$$
$$y=\mathrm{F}(t)\text{ gives }k=y'i+y''\frac{i^2}{2}+\text{\&c.}\ldots\ldots\ldots\ldots(2)$$
$$x=\varphi(t)\text{ gives }h=x'i+x''\frac{i^2}{2}+\text{\&c.}\ldots\ldots\ldots\ldots(3)$$

The three increments k, h, i are generated together, therefore these equations must all hold true at the same time. Let the value of h, found from the third equation, be substituted in the first, then, putting the two values of k equal, we have

$$(y')\left\{x'i+x''\frac{i^2}{2}+\text{\&c.}\right\}$$
$$+\frac{(y'')}{2}\left\{x'i+x''\frac{i^2}{2}+\text{\&c.}\right\}^2+\text{\&c.}$$
$$=y'i+y''\frac{i^2}{2}+\text{\&c.}$$

Hence, by involution, and making the co-efficients of like powers of i equal to zero, as usual, we find

$$x'(y')=y',\quad x''(y')+x'^2(y'')=y'',\ \text{\&c.}$$

therefore $(y')=\frac{y'}{x'}$ $\qquad (y'')=\frac{y''-x''(y')}{x'^2}$, &c.

As an example, let us take the formula for the radius of curvature, which, by the notation just premised, will be

$$r=-\frac{\{1+(y')^2\}^{\frac{3}{2}}}{(y'')^2}.$$

By substituting for (y') and (y'') their values, it becomes

$$r=-\frac{(x'^2+y'^2)^{\frac{3}{2}}}{x'y''-y'x''};$$

and hence, putting $\frac{dx}{dt}$ for x', $\frac{dy}{dt}$ for y', $\frac{d^2x}{dt^2}$ for x'', and $\frac{d^2y}{dt^2}$ for y'', we get

$$r=\frac{(dx^2+dy^2)^{\frac{3}{2}}}{dyd^2x-dxd^2y}.$$

The independent variable t does not appear in the formula; nevertheless, in its application, we must keep in mind the hypothesis by which it was found.

Of the Method of Infinitesimals.

95. The ideas which we have of infinity may be embodied in this proposition: *A quantity is not infinite so long as it admits of augmentation.* If, therefore, in the quantity $x+a$, we suppose x to become infinite, then a must be suppressed, otherwise it would be supposed that x might be increased by the quantity a, which is contrary to the definition. To show the consistency of the proposition, let there be an equation

$$\frac{1}{a}+\frac{1}{x}=\mathrm{M}\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(1)$$

which being multiplied by the product ax, becomes

$$x+a=\mathrm{M}ax\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(2)$$

Suppose now that x increases until it becomes infinite · the fraction $\frac{1}{x}$, having reached its last degree of diminution, is reduced to 0, and therefore equation (1) becomes

$$\mathrm{M}=\frac{1}{a},\text{ or }\mathrm{M}a=1;$$

Direct Method.

and this value being substituted in equation (2), it becomes $x + a = x$. This shows that when x is infinite, $x + a$ is reduced to x.

The quantity a, in respect of which x is infinite, is called an *infinitesimal* in respect of x.

Since we consider here only the ratios of quantities, the preceding demonstration holds good when x has a finite value, provided that a be infinitely small in respect of x. Thus, if we compare b, a finite quantity, with the fraction $\frac{b}{z}$, then, z being supposed to increase continually, $\frac{b}{z}$ will decrease, and may become smaller than any assignable quantity; and when z is infinite, the fraction is $= 0$, so that, in comparison with b, it may be neglected.

The ratios of quantities are altogether independent of their absolute magnitude. The halves, or any like parts of quantities, have the same ratios as the wholes. The symbols we employ in our reasonings are not the representatives of absolute magnitudes, but of numbers, which have a reference to an unit; they therefore represent ratios only, and the absolute magnitudes of the terms of the ratios are never considered. The differentials of quantities are the ratios to which the ratios of the increments of the variables continually approach; these increments may have any magnitude whatever. Leibnitz supposed them to be infinitely small quantities. Upon this hypothesis a theory has been constructed, which, by following certain ascertained principles, has led to the discovery of the most recondite truths in geometry and physics.

96. The admission of infinitesimals into the mathematical sciences, necessarily leads to a succession of different orders of infinitesimals. In a circle the ratio of the diameter to the chord of an arc is the same as the ratio of the chord to the versed sine; therefore, if the chord be infinitely small in respect of the diameter, or an infinitesimal of the *first* order, the versed sine will be infinitely small in respect of the chord; and, consequently, in respect of the diameter, will be an infinitesimal of the *second* order. So also, in a series of continued proportionals, 1, x, x^2, x^3, &c. of which the first term is finite, and the second, x, an infinitesimal of the first order, the third, x^2, will be of the second order, and the fourth, x^3, of the third, and so on. Upon the same principle, the product ab of two infinitesimals, a, b of the first order will be an infinitesimal of the second; for we may consider that $1 : a = b : ab$, that is, ab is a fourth proportional to three quantities 1, a, and b, of which the first is finite. In like manner, the product of three infinitesimals of the first order, also the product of an infinitesimal of the first and of the second order, will be an infinitesimal of the third order.

97. When the infinitely small increments of quantities are once taken as their differentials, the different rules for differentiation are easily found.

Thus, if $u = xy$; then u, x, and y receiving the infinitely small augments du, dx, and dy, we have

$$u + du = (x + dx)(y + dy) = xy + xdy + ydx + dxdy;$$

and, taking from these equals the equals u and xy,

$$du = xdy + ydx + dxdy.$$

Now du, xdy, ydx are infinitesimals of the first order, and $dxdy$ is an infinitesimal of the second, therefore it is incomparably smaller, and in respect of the others ought to be rejected, so that we have simply

$$du = xdy + ydx.$$

98. In this theory a curve is considered as a polygon of an infinite number of sides, any one of which is the differential of the arc, therefore the differential of the arc will be the hypotenuse of a right-angled triangle, of which the sides are the differentials of the co-ordinates; and these being denoted by x and y, and the arc by z, we have $dz^2 = dx^2 + dy^2$. Proceeding on the same principles, if s denote the area of a curve, the increment of s or ds will be $ydx + \frac{1}{2}dxdy$; but the second part of this, viz. $\frac{1}{2}dxdy$, is a differential of the second order, and therefore infinitely less than ydx, which is of the first order, therefore we have simply $ds = ydx$, agreeing with the formula of art. 69.

Inverse Method.

In a circle, the infinitely small increments of the cosine, the sine, and the arc form a right-angled triangle similar to that formed by the sine, the cosine, and the radius, so that x being put for the arc, the radius being unity,

$1 : \cos x = dx : d \sin x$, $1 : \sin x = dx : -d \cos x$, hence $d \sin x = dx \cos x$, and $d \cos x = -xdx$.

It is equally manifest, according to the infinitesimal theory, that the subtangent is a fourth proportional to dx (the differential of the absciss), dy (the differential of the ordinate), and y the ordinate; so that, as has been shown, art. 65,

$$\text{subtan} = \frac{\pm dy}{dx} y;$$

the positive sign being used if the absciss and ordinate increase together, otherwise the sign $-$.

The great facility which the theory of infinitesimals gives in the applications of the calculus to the higher geometry, and more especially to the doctrines of physics, is a high recommendation in its favour. Indeed, whatever view be taken of the subject, the mathematician will hardly be restrained from taking the shortest way he can find to the object he wishes to attain, and that is in general by the infinitesimal calculus. Accordingly we observe that M. Poisson, in the second edition of his *Traité de Mécanique*, distinctly premises that he will exclusively employ the method of *infiniment petits* throughout his work.

PART II.

INVERSE METHOD OF FLUXIONS, OR INTEGRAL CALCULUS.

99. The *inverse method of fluxions*, or *integral calculus*, treats of the analytic processes by which a function may be found, such, that being differentiated, it shall produce a given differential. This function has been called, by writers on fluxions, the *fluent* or *flowing quantity;* and by writers on the differential calculus, the *integral* of the proposed differential.

To find the integral of a differential is to *integrate* that differential; and the process by which the integral is found is called *integration.*

100. When an integral is proposed, its differential may always be found by general rules. There is however no direct rule by which we may return from the differential to the integral, except the obvious one of retracing the steps by which the differential has been deduced from the integral. When these are distinctly indicated, there is no difficulty; but in general the steps of calculation by which the differential might have been deduced from an integral are obliterated or unknown; or the differential may not have been a direct result of differentiation; and then there will be no traces to show how we may pass from it to the integral.

101. It is convenient to have a symbol by which the integral of a differential may be indicated without regard to its particular form: for this purpose the letter $\int$ (the initial letter of the word *sum*) is employed. Thus, the integral of the differential $\mathrm{X}dx$ is expressed by the symbol $\int \mathrm{X}dx$.

102. We have seen (art. 9) that in differentiating an expression of the form $\mathrm{X} \pm \mathrm{C}$, which is the sum or dif-

Inverse Method.

ference of a variable function and a constant quantity, the constant disappears; therefore, reversely, in taking the integral of any differential, the constant, C, must be added to make the integral complete. This indeterminate quantity has been called by early English writers the *correction* of the fluent or integral, but now it is generally called the *arbitrary constant.* It may be written either with the sign $+$ or $-$; its value is to be determined, as will appear hereafter, from the particular problem under consideration.

Integration of Rational Functions involving one Variable.

103. The general form of a differential of the first order of a function is Xdx, where X denotes any function of a single variable x. Now this function may have various forms, and may be rational or irrational.

The rational forms of the function may be

$$Ax^m + Bx^n + Cx^p + \&c. = U,$$

$$\frac{Ax^m + Bx^n + Cx^p + \&c.}{A'x^{m'} + B'x^{n'} + C'x^n + \&c.} = \frac{U}{V},$$

the first of which is integral and the second fractional.

Irrational functions have the form

$$UV^{\frac{m}{n}},$$

and transcendental functions,

$$f(U, \text{l. } U),\ f(U, \sin v),\ \&c.$$

104. The simplest case of a rational function is ax^n, the differential of which is $nax^{n-1}dx$; therefore, putting $m = n - 1$, so that $n = m + 1$, we have,

when $dy = ax^m dx$,

$$\text{then } y = \int ax^m dx = \frac{a}{m+1} x^{m+1} + \text{C}.$$

Hence this rule: *To integrate a differential of one term, such as* $ax^n dx$, *we must increase the exponent of the variable by an unit, and then divide by the new exponent and by* dx.

We may give the indeterminate constant C the form $-\frac{ab^{n+1}}{n+1}$, and then we shall have

$$\int ax^n dx = \frac{a(x^{n+1} - b^{n+1})}{n+1}.$$

This is the form the integral should have, if it has the property of vanishing in the particular case of $x = b$.

105. There is a particular case to which the general rule of last article will not immediately apply; it is that in which $n = -1$; in that case it gives

$$\int \frac{adx}{x} = \int ax^{-1}dx = \frac{a(x^0 - b^0)}{0} = \frac{a(1-1)}{0} = \frac{0}{0}.$$

From this no conclusion can be drawn, and the integral has been said to *fail.* This, however, is only in appearance; for, putting $n+1 = m$, we have (art. 35)

$$x^m = 1 + (\text{l. } x)\, m + (\text{l. } x)^2 \frac{m^2}{1 \cdot 2} + \&c.$$

$$b^m = 1 + (\text{l. } b)\, m + (\text{l. } b)^2 \frac{m^2}{1 \cdot 2} + \&c.$$

$$x^m - b^m = \{\text{l. } x - \text{l. } b\}\, m + \{(\text{l. } x)^2 - (\text{l. } b)^2\} \frac{m^2}{1 \cdot 2} + \&c.$$

$$\frac{x^m - b^m}{m} = \text{l. } x - \text{l. } b + \{(\text{l. } x)^2 - (\text{l. } b)^2 \frac{m}{2} + \&c.$$

This, when $n+1 = m = 0$ and $n = -1$, gives

$$\int \frac{adx}{x} = a\{\text{l. } x - \text{l. } b\} = a \text{ l. } x + \text{C}.$$

This result coincides entirely with the expression for the differential of the logarithm of a number (art. 20).

106. By the rule of art. 104 it is evident that if

$$dy = ax^m dx + bx^n dx + cx^p dx,$$

$$\text{then, } y = \frac{ax^{m+1}}{m+1} + \frac{bx^{n+1}}{n+1} + \frac{cx^{p+1}}{p+1} + \text{C}.$$

This is true, however many terms there may be in the differential: the indeterminate constant C represents the aggregate of all the constants of the integrals of the several terms.

In general, since (art. 15),

$$d(u + v - z) = du + dv - dz,$$

$$\text{therefore } u + v - z = \int du + \int dv - \int dz;$$

and in general, P, Q, R, being any functions of x,

$$\int (\text{P}dx + \text{Q}dx - \text{R}dx) = \int \text{P}dx + \int \text{Q}dx - \int \text{R}dx.$$

107. It has been found that u and v being any functions of a variable, $d(uv) = udv + vdu$, therefore

$$\int udv = uv - \int vdu.$$

In like manner, from the differential of a fraction we find

$$\int u \frac{dv}{v^2} = -\frac{u}{v} + \int \frac{du}{v}.$$

Since $d(au) = adu$, we may conclude that

$$\int a\text{X}dx = a \int \text{X}dx.$$

108. To integrate the differential

$$dy = (ax + b)^m dx,$$

we may expand the given power, and integrate the terms of the result separately; otherwise, make $z = ax + b$, then

$$x = \frac{z - b}{a},\ dx = \frac{dz}{a}.$$

By substitution, we have now $dy = \frac{z^m dz}{a}$, and by integration,

$$y = \frac{z^{m+1}}{a(m+1)} + \text{C} = \frac{(ax + b)^{m+1}}{a(m+1)} + \text{C}.$$

The integral of $dy = (ax^n + b)^m x^{n-1} dx$ may be found in the same way, by putting $ax^n + b = z$; we thus get

$$y = \frac{(ax^n + b)^{m+1}}{na(m+1)} + \text{C}.$$

109. We shall next consider fractional functions, and begin with the simple case of $dy = \frac{\text{A}x^m dx}{(ax + b)^n}$; making $z = ax + b$, we find

$$x = \frac{z - b}{a},\ dx = \frac{dz}{a},$$

and consequently

$$dy = \frac{\text{A}(z - b)^m dz}{a^{m+1} z^n}.$$

By expanding $(z - b)^m$ into a series, then multiplying the terms by dz, and dividing by z^n, the differential will be transformed into a series of terms of the form $cz^p dz$, which

Inverse Method.

may be integrated severally by the rule (art 104). As a particular example, let $m=3$, $n=2$, then

$$dy=\frac{A(z-b)^3dz}{a^4z^2}$$

$$=\frac{A}{a^4}\left\{zdz-3bdz+3b^2z^{-1}dz-b^3z^{-2}dz\right\}:$$

Hence, integrating by the rule,

$$y=\frac{A}{a^4}\left\{\frac{z^2}{2}-3bz+3b^2\,\mathrm{l}.z+b^3z^{-1}\right\}+C.$$

We now substitute for z its value, and find

$$y=\frac{A}{a^4}\left\{\begin{matrix}\frac{1}{2}(ax+b)^2-3b(ax+b)\\ +3b^2\,\mathrm{l}.(ax+b)+\dfrac{b^3}{ax+b}\end{matrix}\right\}+C.$$

110. All differentials which are rational fractions may be reduced to this form,

$$\frac{(Ax^{n-1}+Bx^{n-2}+Cx^{n-3}\ldots+T)dx}{x^n+A'x^{n-1}+B'x^{n-2}\ldots+T'}.$$

The general method of integrating such a differential consists in decomposing it into others whose denominators are more simple, which are called *partial fractions.* These are obtained as follows.

Assume the denominator of the proposed fraction equal to *zero*, thus forming the equation

$$x^n+A'x^{n-1}+B'x^{n-2}\ldots\ldots+T'=0.$$

Let the roots of this equation be

$$x=-a,\ x=-a',\ x=-a'',\ x=-a''',\ \&c.$$

and supposing them all different, the first side of the equation will be (ALGEBRA, art. 99) the product of n factors,

$$x+a,\ x+a',\ x+a'',\ x+a''',\ \&c.$$

We now assume that the proposed fraction is the sum of the fractions

$$\frac{Ndx}{x+a},\ \frac{N'dx}{x+a'},\ \frac{N''dx}{x+a''},\ \&c.$$

of which the denominators are the factors of the proposed fraction, and the numerators are undetermined constants. These being reduced to a common denominator, and added, the result will be a fraction identical with the proposed fraction; and by putting the co-efficients of like powers of x in their numerators equal to one another, a series of equations will be had, by which the undetermined constants N, N′, N″, &c. may be found.

As an example, suppose the differential to be integrated is

$$\frac{(Ax^2+Bx+C)\,dx}{x^3+A'x^2+B'x+C'},$$

and that by the resolution of an equation we know that

$$x^3+A'x^2+B'x+C'=(x+a)(x+a')(x+a'').$$

setting aside dx, we assume that the fraction is equivalent to

$$\frac{N}{x+a}+\frac{N'}{x+a'}+\frac{N''}{x+a''}.$$

The sum of these is

$$\frac{N(x+a')(x+a'')+N'(x+a)(x+a'')+N''(x+a)(x+a')}{(x+a)(x+a')(x+a'')}.$$

The numerator of this fraction is, by multiplying its factors,

$$(N+N'+N'')x^2+\{N(a'+a'')+N'(a+a'')+N''(a+a')\}x$$
$$+Na'a''+N'aa''+N''aa';$$

and as this must be equal to the numerator of the proposed differential, whatever be the value of x, the co-efficients of like powers of x will be equal (art. 18); hence we have these three equations,

$$N+N'+N''=A.$$
$$N(a'+a'')+N'(a+a'')+N''(a+a')=B,$$
$$Na'a''+N'aa''+N''aa'=C;$$

Inverse Method.

which are only of the first degree with respect to the undetermined quantities N, N′, N″. Resolving these equations, we find N, N′, N″, and have

$$\frac{(Ax^2+Bx+C)dx}{x^3+A'x^2+B'x+C'}$$
$$=\frac{Ndx}{x+a}+\frac{N'dx}{x+a'}+\frac{N''dx}{x+a''}.$$

Making $x+a=z$, we have $dx=dz$, and $\frac{Ndx}{x+a}=\frac{Ndz}{z}$, the integral of which is $N\,\mathrm{l}.z=N\,\mathrm{l}.(x+a)$; similarly,

$$\int\frac{N'dx}{x+a'}=N'\,\mathrm{l}.(x+a');\int\frac{N''dx}{x+a'}=N''\,\mathrm{l}.(x+a'').$$

So that we have now

$$\int\frac{(Ax^2+Bx+C)dx}{x^3+A'x^2+B'x+C'}$$
$$=N\,\mathrm{l}.(x+a)+N'\mathrm{l}.(x+a')+N''\mathrm{l}.(x+a'')+\text{const.}$$
$$=\mathrm{l}.\left\{(x+a)^{N}\cdot(x+a')^{N'}\cdot(x+a'')^{N''}\right\}+\text{const.}$$

This process, which may be extended to all rational fractions whose denominators are decomposable into unequal factors of the *first* degree, has no difficulty, independent of the decomposition of the denominator into its factors, which, however, requires the numerical resolution of equations.

111. If some of the factors of the denominator of the proposed fraction are equal, the process will require to be modified to suit that case. Suppose the denominator $x^n+A'x^{n-1}+$, &c.... $+T'$ to contain a factor $(x+a)^p$, then, for every such factor, it will be necessary to assume a partial fraction of the form

$$\frac{(Px^{p-1}+Qx^{p-2}+,\ \&c.\ldots+Y)dx}{(x+a)^p}.$$

This and the other partial fractions being reduced to a common denominator, and added, and the terms of the numerator in the result being put equal to those of the numerator of the proposed differential, as before, as many independent equations will be obtained as there are co-efficients to be determined.

112. It is not difficult to see that the partial fraction suited to the case of equal factors may be transformed into an expression of the form

$$\frac{Ndx}{(x+a)^p}+\frac{N'dx}{(x+a)^{p-1}}\cdots+\frac{N''dx}{x+a};$$

therefore we may at once substitute this instead of the equivalent single fraction. We shall now have to integrate a series of differentials of the form

$$\frac{Ndx}{(x+a)^p},$$

which, by making $x+a=z$, and therefore $dx=dz$, gives

$$\int\frac{Ndx}{(x+a)^p}=\int\frac{Ndz}{z^p}=\frac{Nz^{-p+1}}{1-p}$$
$$=\frac{N}{(1-p)(x+a)^{p-1}}.$$

These will be all algebraical except the last, $\int\frac{Ndx}{x+a}$, which will involve a logarithm.

113. If there be imaginary factors, these will occur in pairs of the form $x+\alpha+\beta\sqrt{-1}$, $x+\alpha-\beta\sqrt{-1}$,

Inverse Method.

and their product will be $x^2+2\alpha x+\alpha^2+\beta^2$. In this case the best way to proceed will be to resolve the denominator of the proposed differential into real factors of the first and of the second degree, which is always possible (see EQUATIONS). If there be several pairs of these imaginary factors, each pair the same, the denominator of the proposed differential will have factors of the form $(x^2+2\alpha x+\alpha^2+\beta^2)^q$. Then, for the single factor $x^2+2\alpha x+\alpha^2+\beta^2$, we must assume, in addition to the partial fractions, for factors of the first degree, one of this form,

$$\frac{(\mathrm{K}x+\mathrm{L})dx}{x^2+2\alpha x+\alpha^2+\beta^2};$$

and for factors of the second form, this fraction,

$$\frac{(\mathrm{Q}x^{2q-1}+\mathrm{R}x^{2q-2}\ldots+\mathrm{Y}')\,dx}{(x^2+2\alpha x+\alpha^2+\beta^2)^q};$$

or, instead of this, a series of fractions,

$$\frac{(\mathrm{K}x+\mathrm{L})\,dx}{(x^2+2\alpha x+\alpha^2+\beta^2)^q}+\frac{(\mathrm{K}'x+\mathrm{L}')dx}{(x^2+2\alpha x+\alpha^2+\beta^2)^{q-1}}$$

$$\ldots\ldots\ldots\ldots\ldots\ldots+\frac{(\mathrm{K}'''x+\mathrm{L}''')dx}{x^2+2\alpha x+\alpha^2+\beta^2};$$

the co-efficients to be determined, as before explained.

114. To integrate the fraction

$$\frac{(\mathrm{K}x+\mathrm{L})\,dx}{x^2+2\alpha x+\alpha^2+\beta^2},$$

we observe that $x^2+2\alpha x+\alpha^2+\beta^2=(x+\alpha)^2+\beta^2$; and if we make $x+\alpha=z$, then

$$\frac{(\mathrm{K}x+\mathrm{L})dx}{(x+\alpha)^2+\beta^2}=\frac{(\mathrm{K}z+\mathrm{L}-\mathrm{K}\alpha)dz}{z^2+\beta^2}$$

$$=\frac{\mathrm{K}zdz}{z^2+\beta^2}+\frac{\mathrm{L}'dz}{z^2+\beta^2}.$$

Here L' is put for the constant quantity $\mathrm{L}-\mathrm{K}\alpha$. Now, the integral of the first of these differentials may be expressed by a logarithm; for, making $z^2+\beta^2=u$, we have $zdz=\frac{1}{2}du$, which gives

$$\int\frac{\mathrm{K}zdz}{z^2+\beta^2}=\frac{\mathrm{K}}{2}\int\frac{du}{u}=\mathrm{K}\tfrac{1}{2}\,\mathrm{l}.\,u=\mathrm{K}\,\mathrm{l}.\sqrt{z^2+\beta^2}.$$

With respect to the second part, we make $z=\beta v$, then,

$$\frac{\mathrm{L}'dz}{z^2+\beta^2}=\frac{\mathrm{L}'}{\beta}\,\frac{dv}{v^2+1}.$$

But we have found (art. 23) that $\frac{dv}{v^2+1}$ is the differential of the arc whose tangent is v, which is expressed by $\tan^{-1}v$, therefore

$$\int\frac{\mathrm{L}'}{\beta}\cdot\frac{dv}{v^2+1}=\frac{\mathrm{L}'}{\beta}\tan^{-1}v+\text{const.}$$

$$=\frac{\mathrm{L}'}{\beta}\tan^{-1}\frac{z}{\beta}+\text{const.}$$

Adding now these results, we get

$$\int\frac{(\mathrm{K}z+\mathrm{L}')dz}{z^2+\beta^2}=\mathrm{K}\,\mathrm{l}.\sqrt{z^2+\beta^2}+\frac{\mathrm{L}'}{\beta}\tan^{-1}\frac{z}{\beta}+\text{const.}$$

When the value of z and L' are replaced, we have

$$\int\frac{(\mathrm{K}x+\mathrm{L})dx}{x^2+2\alpha x+\alpha^2+\beta^2}=\text{const.}$$

$$+\mathrm{K}\,\mathrm{l}.\sqrt{x^2+2\alpha x+\alpha^2+\beta^2}+\frac{\mathrm{L}-\mathrm{K}\alpha}{\beta}\tan^{-1}\frac{x+\alpha}{\beta}.$$

115. To integrate the differential

$$\frac{(\mathrm{K}x+\mathrm{L})dx}{(x^2+2\alpha x+\alpha^2+\beta^2)^q},$$

we shall at once make $x+\alpha=z$, and $\mathrm{L}-\mathrm{K}\alpha=\mathrm{L}'$. By this the differential is transformed to

Inverse Method.

$$\frac{(\mathrm{K}z+\mathrm{L}')dz}{(z^2+\beta^2)^q}=\frac{\mathrm{K}zdz}{(z^2+\beta^2)^q}+\frac{\mathrm{L}'dz}{(z^2+\beta^2)^q}.$$

To transform the first part, we make $z^2+\beta^2=u$, so that $zdz=\frac{du}{2}$, and consequently,

$$\int\frac{\mathrm{K}zdz}{(z^2+\beta^2)^q}=\frac{\mathrm{K}}{2}\int\frac{du}{u^q}=\frac{\mathrm{K}}{2}\cdot\frac{u^{-q+1}}{1-q}.$$

To integrate the second part, we assume the equation

$$\int\frac{dz}{(z^2+\beta^2)^q}=\frac{\mathrm{G}z}{(z^2+\beta^2)^{q-1}}+\mathrm{H}\int\frac{dz}{(z^2+\beta^2)^{q-1}};$$

that is, we assume the integral to be equal to an algebraic quantity, together with another integral whose denominator is less by an unit than the first. We now differentiate the terms of the assumed equation, observing that the removal of $\int$, the sign of an integral, is equivalent to the differentiation of that integral; we also reject such factors as are common to all the terms of the result, and thus have

$$1=\mathrm{G}\,(z^2+\beta^2)-2\,(q-1)\,\mathrm{G}z^2+\mathrm{H}\,(z^2+\beta^2);$$

$$\text{and }\{(3-2q)\,\mathrm{G}+\mathrm{H}\}\,z^2+(\mathrm{G}+\mathrm{H})\,\beta^2-1=0.$$

Now, that z may remain undetermined, we must have

$$(\mathrm{G}+\mathrm{H})\,\beta^2-1=0,\quad(3-2q)\,\mathrm{G}+\mathrm{H}=0.$$

From these equations, we find

$$\mathrm{G}=\frac{1}{(2q-2)\beta^2},\qquad\mathrm{H}=\frac{2q-3}{(2q-2)\beta^2}.$$

The values of G and H being substituted in our assumed equation, it becomes

$$\int\frac{dz}{(z^2+\beta^2)^q}=\frac{1}{(2q-2)\beta^2}\;\frac{z}{(z^2+\beta^2)^{q-1}},$$

$$+\frac{2q-3}{(2q-2)\beta^2}\int\frac{dz}{(z^2+\beta^2)^{q-1}}.$$

This formula gives the means of depressing the index of the denominator of the proposed fraction; for, putting $q-1$ instead of q, we find

$$\int\frac{dz}{(z^2+\beta^2)^{q-1}}=\frac{1}{(2q-4)\beta^2}\;\frac{z}{(z^2+\beta^2)^{q-2}},$$

$$+\frac{2q-5}{(2q-4)\beta^2}\int\frac{dz}{(z^2+\beta^2)^{q-2}};$$

and again, putting $q-2$ for q, we get

$$\int\frac{dz}{(z^2+\beta^2)^{q-2}}=\frac{1}{(2q-6)\beta^2}\;\frac{z}{(z^2+\beta^2)^{q-3}},$$

$$+\frac{2q-7}{(2q-6)\beta^2}\int\frac{dz}{(z^2+\beta^2)^{q-3}}.$$

In this way the integral $\int\frac{dz}{(z^2+\beta^2)^q}$ is expressed by an algebraic quantity, and another integral, $\int\frac{dz}{(z^2+\beta^2)^{q-1}}$; and this last by another algebraic quantity, and the integral $\int\frac{dz}{(z^2+\beta^2)^{q-2}}$; and so on, until we come to the integral $\int\frac{dz}{z^2+\beta^2}$, which is known, and expressible by the arc of a circle. Here the process must stop; for the next transformation would involve the integral $\int\frac{dz}{(z^2+\beta^2)^0}$, with

an infinite co-efficient, from which no conclusion can be drawn. Here we see the application of a method of integration at once fertile and elegant.

From what has been explained, it appears that differentials which are rational fractions may be always integrated either algebraically or by means of logarithms or circular arcs; all that is necessary is to decompose them into partial fractions, whose denominators are either binomial or trinomial quantities.

116. We shall now give some examples of the integration of differentials which are rational fractions.

1. Let the differential be $\frac{adx}{x^2-a^2}$.

In this case the denominator $x^2-a^2=(x-a)(x+a)$; we therefore assume

$$\frac{adx}{(x-a)(x+a)}=\left\{\frac{A}{x-a}+\frac{B}{x+a}\right\}dx.$$

We now reduce the second side to a single fraction, and, leaving out dx, have

$$\frac{a}{(x-a)(x+a)}=\frac{(A+B)x+(A-B)a}{(x-a)(x+a)};$$

therefore $a=(A+B)x+(A-B)a$.

Now, x being indeterminate, according to the principle of art. 18, we must have

$$(A-B)a=a,\quad A+B=0;$$

these equations give $A=\frac{1}{2}$, $B=-\frac{1}{2}$; the proposed differential is now

$$\frac{adx}{x^2-a^2}=\tfrac{1}{2}\frac{dx}{x-a}-\tfrac{1}{2}\frac{dx}{x+a};$$

and, by integrating,

$$\int\frac{adx}{x^2-a^2}=\tfrac{1}{2}\,\mathrm{l.}(x-a)-\tfrac{1}{2}\,\mathrm{l.}(x+a)+C,$$

$$=\tfrac{1}{2}\,\mathrm{l.}\frac{x-a}{x+a}+C=\mathrm{l.}\sqrt{\frac{x-a}{x+a}}+C.$$

2. Let the differential be $\frac{a^3+b^2x^2}{a^2x-x^3}dx$.

The factors of the denominator are x and a^2-x^2, which last resolves into $(a-x)(a+x)$; therefore, leaving out dx, we assume

$$\frac{a^3+bx^2}{x(a-x)(a+x)}=\frac{A}{x}+\frac{B}{a-x}+\frac{C}{a+x}.$$

The second side of this equation, by reducing its terms to a common denominator, and adding, is

$$\frac{Aa^2+a(B+C)x+(B-A-C)x^2}{x(a-x)(a+x)}.$$

By equating the co-efficients of the powers of x, we have

$$Aa^2=a^3,\quad a(B+C)=0,\quad B-A-C=b.$$

Here there are three unknown quantities, viz. A, B, C, and three simple equations, therefore they may be found, as taught in ALGEBRA, sect. viii.; and accordingly we have

$$A=a,\quad B=\tfrac{1}{2}(a+b),\quad C=-\tfrac{1}{2}(a+b),$$

$$\frac{a^3+bx^2}{a^2x-x^3}dx=\frac{adx}{x}+\frac{a+b}{2(a-x)}dx-\frac{a+b}{2(a+x)}dx;$$

and, integrating,

$$\int\frac{a^3+bx^2}{a^2x-x^3}dx=a\,\mathrm{l.}x-\frac{a+b}{2}\,\mathrm{l.}(a-x)$$

$$-\frac{a+b}{2}\,\mathrm{l.}(a+x)+C.$$

By the nature of logarithms $\mathrm{l.}P+\mathrm{l.}Q=\mathrm{l.}(PQ)$ and $n\,\mathrm{l.}P=\mathrm{l.}P^n$; hence the integral may be otherwise expressed thus,

$$\int\frac{a^3+bx^2}{a^2x-x^3}dx=\mathrm{l.}\frac{x^a}{(a^2-x^2)^{\frac{1}{2}(a+b)}}+C.$$

3. Let the differential be $\frac{3x-5}{x^2-6x+8}dx$.

To resolve the denominator into simple factors, we make $x^2-6x+8=0$, and find the roots of this equation to be $x=2$, and $x=4$; therefore, $x^2-6x+8=(x-2)(x-4)$. To decompose the fraction, leaving out dx, we now assume

$$\frac{3x-5}{(x-2)(x-4)}=\frac{A}{x-2}+\frac{B}{x-4},$$

$$=\frac{(A+B)x-4A-2B}{(x-2)(x-4)}.$$

Hence, equating the like terms in the numerators, we have

$$A+B=3,\quad -4A-2B=-5.$$

From these equations we find $A=-\frac{1}{2}$, $B=\frac{7}{2}$, and

$$\int\frac{(3x-5)dx}{x^2-6x+8}=-\tfrac{1}{2}\int\frac{dx}{x-2}+\frac{7}{2}\int\frac{dx}{x-4},$$

$$=\frac{7}{2}\,\mathrm{l.}(x-4)-\tfrac{1}{2}\,\mathrm{l.}(x-2)+C.$$

4. As an example of equal simple factors in the denominator, let the differential be

$$\frac{x^2dx}{(x^2-a^2)(x-a)}=\frac{x^2dx}{(x-a)^2(x+a)}.$$

In this case we assume (art. 112),

$$\frac{x^2}{(x-a)^2(x+a)}=\frac{A}{(x-a)^2}+\frac{B}{x-a}+\frac{C}{x+a}$$

$$=\frac{A(x+a)+B(x^2-a^2)+C(x-a)^2}{(x-a)^2(x+a)}$$

$$=\frac{Aa-Ba^2+Ca^2+(A-2aC)x+(B+C)x^2}{(x-a)^2(x+a)}.$$

By equating like terms of the numerators, we have

$$Aa-Ba^2+Ca^2=0,\quad A-2aC=0,\quad B+C=1.$$

Hence, by the ordinary process for resolving simple equations involving three unknown quantities, we find

$$A=\tfrac{1}{2}a,\quad B=\tfrac{3}{4},\quad C=\tfrac{1}{4},$$

and the transformed differential is

$$\frac{x^2dx}{(x-a)^2(x+a)}=\frac{a}{2}\frac{dx}{(x-a)^2}+\tfrac{3}{4}\frac{dx}{x-a}+\tfrac{1}{4}\frac{dx}{x+a}.$$

By integration we have

$$\int\frac{dx}{(x-a)^2}=\frac{-1}{x-a},\ \int\frac{dx}{x-a}=\mathrm{l.}(x-a),\ \int\frac{dx}{x+a}=\mathrm{l.}(x+a);$$

therefore, supplying the co-efficients of the partial fractions, and, as usual, an indeterminate constant, we have

$$\int\frac{x^2dx}{(x^2-a^2)(x-a)}=-\frac{a}{2}\frac{1}{x-a}+\tfrac{3}{4}\,\mathrm{l.}(x-a)$$

$$+\tfrac{1}{4}\,\mathrm{l.}(x+a)+\mathit{const.}$$

5. Let the differential be $\frac{x^3+x^2+2}{x(x+1)^2(x-1)^2}dx$.

The denominator contains two pairs of equal factors; we therefore assume (art. 112) $\frac{x^3+x^2+2}{x(x+1)^2(x-1)^2}$ equal to

$$\frac{A}{x}+\frac{B}{(x+1)^2}+\frac{C}{(x+1)}+\frac{D}{(x-1)^2}+\frac{E}{x-1}.$$

By proceeding as in the foregoing examples, uniting the partial fractions into one fraction, and equating the co-efficients of like powers of x, we find

$$A=2,\ B=-\tfrac{1}{2},\ C=-\tfrac{5}{4},\ D=1,\ E=-\tfrac{3}{4}.$$

The proposed differential is now decomposed into these,

$$\frac{2dx}{x} - \frac{1}{2}\frac{dx}{(x+1)^2} - \frac{5}{4}\frac{dx}{x+1} + \frac{dx}{(x-1)^2} - \frac{3}{4}\frac{dx}{x-1}.$$

Hence, by integration,

$$\int \frac{x^3+x^2+2}{x(x+1)^2(x-1)^2}dx = 2\,\mathrm{l}.\,x + \frac{1}{2}\frac{1}{x+1} - \frac{5}{4}\mathrm{l}.\,(x+1)$$
$$-\frac{1}{x-1} - \frac{3}{4}\mathrm{l}.\,(x-1) + \text{const.}$$

6. As an example of a fraction, in which one of the factors in the denominator is a function of the second degree, which does not admit of resolution into real factors of the first degree, let the differential to be integrated be $\frac{a+bx}{x^3-1}dx.$

The denominator $x^3 - 1 = (x-1)(x^2+x+1)$. The expression $x^2 + x + 1$ is of that kind which cannot be resolved into real factors, although it may into two imaginary factors. For, making $x^2 + x + 1 = 0$, and resolving this quadratic equation, we find $x = \frac{-1 \pm \sqrt{-3}}{2}$, and $x^2 + x + 1 = (x + \frac{1}{2} + \frac{1}{2}\sqrt{-3})(x + \frac{1}{2} - \frac{1}{2}\sqrt{-3})$.

To avoid impossible quantities, we assume (art. 113),

$$\frac{a+bx}{(x-1)(x^2+x-1)} = \frac{A}{x-1} + \frac{Bx+C}{x^2+x-1}.$$

Reducing now the partial fractions to a common denominator, and comparing the co-efficients of like powers, we find

$A = \frac{1}{3}(a+b)$, $B = -\frac{1}{3}(a+b)$, $C - \frac{1}{3}(2a-b)$.

The proposed differential and its equivalent transformed expression will therefore be

$$\frac{a+bx}{(x-1)(x^2+x+1)}dx = \frac{a+b}{3}\cdot\frac{dx}{x-1}$$
$$-\frac{1}{3}\frac{(a+b)x+2a-b}{x^2+x+1}dx.$$

The first integral of these differentials is expressible by a logarithm; to transform the second, we put $x^2 + x + 1$ under the form $(x+\frac{1}{2})^2 + \frac{3}{4}$, and make $x + \frac{1}{2} = z$; then, $x = z - \frac{1}{2}$, $dx = dz$, $(a+b)x + 2a - b = (a+b)z + \frac{3}{2}(a-b)$, and

$$\frac{1}{3}\frac{(a+b)x+2a-b}{x^2+x+1}dx = \frac{a+b}{3}\frac{zdz}{z^2+\frac{3}{4}}$$
$$+\frac{a-b}{2}\frac{dz}{z^2+\frac{3}{4}}.$$

The first of these two is also expressible by a logarithm. To simplify the second, we make $z^2 = \frac{3}{4}v^2$; so that $dz = \frac{\sqrt{3}}{2}dv$, and $\frac{dz}{z^2+\frac{3}{4}} = \frac{2}{\sqrt{3}}\frac{dv}{1+v^2}$. On the whole, the differential prepared for integration by known rules is

$$\frac{(a+bx)dx}{x^3-1} = \frac{a+b}{3}\frac{dx}{x-1} - \frac{a+b}{3}\frac{zdz}{z^2+\frac{3}{4}}$$
$$-\frac{a-b}{\sqrt{3}}\frac{dv}{1+v^2};$$

and, integrating,

$$\int\frac{(a+bx)dx}{x^3-1} = \frac{a+b}{3}\mathrm{l}.\,(x-1) - \frac{a+b}{6}\mathrm{l}.\,(z^2+\tfrac{3}{4})$$
$$-\frac{a-b}{\sqrt{3}}\tan^{-1}v + \text{const.};$$

this integral, by putting for z and v their values in terms of x, will also be

$$\int\frac{(a+bx)dx}{x^3-1} = \frac{a+b}{3}\mathrm{l}.\,\frac{x-1}{\sqrt{x^2+x+1}}$$
$$-\frac{a-b}{\sqrt{3}}\tan^{-1}\left\{\frac{2x+1}{\sqrt{3}}\right\} + \text{const.}$$

117. The method of resolving a rational fraction into its component partial fractions, by the theory of indeterminate co-efficients (art. 110–113), is the most elementary of any; it is however tedious. We shall therefore now show how the labour may be abridged.

Let $\frac{U}{V}$ be a rational fraction in its lowest terms, the denominator of which has unequal divisors of the first degree; let $x + a$ be one of them, and Q the product of all the other factors, whether of the first or second degree; so that

$$V = (x+a)Q.$$

In this case we assume

$$\frac{U}{V} = \frac{A}{x+a} + \frac{P}{Q},$$

where A is independent of x, and P and Q are functions of x, the latter being supposed known. By reducing to a common denominator, and remembering that $V = (x+a)Q$, we have the identical equation

$$U = AQ + P(x+a),$$

in which, by hypothesis, neither U nor Q are divisible by $x + a$. Let us make $x + a = 0$, that is, $x = -a$, and upon that hypothesis let u and q denote the values of U and Q respectively; then the equation becomes $u = Aq$, and hence $A = \frac{u}{q}$. This determines the numerator of the partial fraction $\frac{A}{x+a}$, and in the same way may the numerators of all the partial fractions be found.

As an example, let the fraction to be resolved be

$$\frac{U}{V} = \frac{mx+n}{(x+a)(x-b)} = \frac{A}{x+a} + \frac{B}{x-b};$$

$$\text{then, } \frac{mx+n}{x-b} = A + \frac{B}{x-b}(x+a),$$

$$\text{and } \frac{mx+n}{x+a} = B + \frac{A}{x+a}(x-b).$$

Making $x = -a$, the first of these gives

$$A = \frac{-ma+n}{-a-b} = \frac{ma-n}{a+b};$$

and making $x = +b$, the second gives $B = \frac{mb+n}{a+b}$.

Hence we have

$$\frac{mx+n}{(x+a)(x-b)} = \frac{1}{a+b}\left\{\frac{ma-n}{x+a} + \frac{mb+n}{x-b}\right\}.$$

118. The differential calculus may be applied to the determination of the constants A, B, &c. Resuming the equation $V = (x+a)Q$, we have, by differentiation, $\frac{dV}{dx} = Q + \frac{dQ}{dx}(x+a)$. Suppose that when $x = -a$, then $\frac{dV}{dx}$ becomes v', and, as before, that Q becomes q, the differential equation will now become $v' = q$; and since $A = \frac{u}{q}$, therefore also $A = \frac{u}{v'}$.

In the preceding example, in which $V = (x+a)(x-b)$, we have

$$\frac{dV}{dx} = 2x + a - b.$$

The supposition that $x = -a$ makes $\frac{dV}{dx} = -a - b = v'$, and the supposition that $x = +b$ makes $\frac{dV}{dx} = a + b = v'$; these values of $v' = q$ give the values of A and B, the same as before.

Inverse Method.

119. Let us now suppose, that in the fraction $\frac{U}{V}$, the denominator $V = (x + a)^n Q$, that is, the product of n equal factors, and Q, the product of all the remaining factors; so that the assumption is $\frac{U}{V} = \frac{U}{Q(x+a)^n} =$

$$\frac{A}{(x+a)^n} + \frac{B}{(x+a)^{n-1}} + \frac{C}{(x+a)^{n-2}} \ldots + \frac{E}{x+a} + \frac{P}{Q},$$

where A, B, C, ...E are constant quantities, and P, Q functions of x. In this case, multiplying all the terms by $(x+a)^n$, we have

$$\frac{U}{Q} = A + B(x+a) + C(x+a)^2 \ldots$$
$$+ E(x+a)^{n-1} + \frac{P}{Q}(x+a)^n.$$

The supposition that $x = -a$ gives to U and Q particular values, which, as before, we denote by u and q; the terms which contain $x + a$ all vanish, and we have $A = \frac{u}{q}$; thus A is known.

Since $\frac{U - AQ}{Q} = B(x+a) + C(x+a)^2 + \&c.$ the numerator, $U - AQ$, of the first side of the equation must necessarily be divisible by $x + a$, and may be expressed by $U_1 (x + a)$. We have now

$$\frac{U_1}{Q} = B + C(x+a) \ldots + E(x+a)^{n-2} + \frac{P}{Q}(x+a)^{n-1}.$$

The quantity U_1 not being divisible by $x + a$, the assumption that $x = -a$ will give it a particular value, which we shall denote by u_1. This assumption will give Q the same particular value as before; the terms which contain $(x + a)$ as a factor will all vanish, and we shall have $B = \frac{u_1}{q}$. In this way may all the remaining numerators C, &c. to E be found.

As a particular example of this process, let the fraction $\frac{U}{V}$ be $\frac{x^2}{(1-x)^3(1+x^2)}$. We assume

$$\frac{x^2}{(1+x^2)(1-x)^3} = \frac{A}{(1-x)^3} + \frac{B}{(1-x)^2} + \frac{C}{1-x} + \frac{P}{1+x^2};$$

hence, multiplying by $(1-x)^3$, we have

$$\frac{x^2}{1+x^2} = A + B(1-x) + C(1-x)^2 + \frac{P}{1+x^2}(1-x)^3.$$

Making $1 - x = 0$, or $x = 1$, we have $A = \frac{1}{2}$, and $\frac{x^2}{1+x^2}$

$$-A = -\frac{1+x}{2(1+x^2)}(1-x) = B(1-x) + C(1-x)^2 + \frac{P}{1+x^2}(1-x)^3,$$

and $-\frac{1+x}{2(1+x^2)} = B + C(1-x) + \frac{P}{1+x^2}(1-x)^2$;

again, making $x = 1$, we find $B = -\frac{1}{2}$, and

$$-\frac{1+x}{2(1+x^2)} - B = \frac{-x}{2(1+x^2)}(1-x) = C(1-x) + \frac{P}{1+x^2}(1-x)^2;$$

and $\frac{-x}{2(1+x^2)} = C + \frac{P}{1+x^2}(1-x)$.

Lastly, making $x = 1$, we have $C = -\frac{1}{4}$, and the fraction

$$\frac{x^2}{(1+x^2)(1-x)^3} = \frac{1}{2}\frac{1}{(1-x)^3} - \frac{1}{2}\frac{1}{(1-x)^2} - \frac{1}{4}\frac{1}{1-x} + \frac{P}{1+x^2}.$$

120. In this case we may also find the numerators A, B, C, &c. by the differential calculus. From the equation of art. 119 we have

$$U = Q\begin{cases} A + B(x+a) + C(x+a)^2 \ldots \\ + E(x+a)^{n-1} + P(x+a)^n. \end{cases}$$

If we now differentiate this equation $(n-1)$ times in succession, and then make $x + a = 0$, both in this equation and those which we deduce from it, there will arise

$$U = AQ,$$
$$\frac{dU}{dx} = A\frac{dQ}{dx} + BQ,$$
$$\frac{d^2U}{dx^2} = A\frac{d^2Q}{dx^2} + 2B\frac{dQ}{dx} + 2CQ,$$
$$\frac{d^3U}{dx^3} = A\frac{d^3Q}{dx^3} + 3B\frac{d^2Q}{dx^2} + 6C\frac{dQ}{dx} + 6DQ,$$
&c.

equations which determine each of the unknown quantities A, B, C, &c. by means of those which precede it, it being well understood that we substitute after each differentiation $-a$ in the place of x in the differential co-efficients. In this case the most simple way of determining Q will be to divide V by $(x-a)^n$. But it may also be found by differentiation, as in art. 118.

121. Let us now suppose that $\frac{U}{V}$, the fraction to be decomposed, has a factor of the second degree, viz. $x^2 + 2\alpha x + \alpha^2 + \beta^2$, which cannot be resolved into two real factors of the first degree.

In this case, $V = (x^2 + 2\alpha x + \alpha^2 + \beta^2)Q$, and we assume

$$\frac{U}{V} = \frac{Ax + B}{x^2 + 2\alpha x + \alpha^2 + \beta^2} + \frac{P}{Q}.$$

Then, $U = (Ax + B)Q + P(x^2 + 2\alpha x + \alpha^2 + \beta^2)$.

If we substitute for x one of the imaginary roots of the equation $x^2 + 2\alpha x + \alpha^2 + \beta^2 = 0$, the term containing P will disappear, and the result will contain two kinds of terms; one real, and the other imaginary. We must now put the real quantities equal to each other, and also the imaginary quantities; thus two equations will be obtained by which A and B may be determined.

Let the fraction be

$$\frac{x}{(x-1)(x^2+x+1)} = \frac{Ax + B}{x^2 + x + 1} + \frac{P}{Q}.$$

Then $x = (Ax + B)(x - 1) + P(x^2 + x + 1)$.

Now $x^2 + x + 1 = 0$ gives $x = -\frac{1}{2} \pm \frac{1}{2}\sqrt{-3}$; therefore, by substituting in the last equation, it becomes, after collecting the terms,

$$-\tfrac{1}{2} \pm \tfrac{1}{2}\sqrt{-3} = -\tfrac{3}{2}B \pm (\tfrac{1}{2}B - A)\sqrt{-3}.$$

Hence $-\frac{3}{2}B = -\frac{1}{2}$ and $\frac{1}{2}B - A = \frac{1}{2}$, therefore $B = \frac{1}{3}$ and $A = -\frac{1}{3}$.

122. In the last place, let us consider the case in which the fraction $\frac{U}{V} =$

$$\frac{Ax + B}{(x^2 + 2\alpha x + \alpha^2 + \beta^2)^n} + \frac{Cx + D}{(x^2 + 2\alpha x + \alpha^2 + \beta^2)^{n-1}} \ldots\ldots + \frac{P}{Q};$$

and here $V = (x^2 + 2\alpha x + \alpha^2 + \beta^2)^n Q$. We have now

$$\frac{U}{Q} = (Ax + B) + (Cx + D)(x^2 + 2\alpha x + \alpha^2\beta^2) \ldots$$
$$+ \frac{P}{Q}(x^2 + 2\alpha x + \alpha^2 + \beta^2)^n V.$$

This case is compounded of the two preceding, and must be treated in the same manner. In the first place, we substitute for x, one of the roots of the equation, $x^2 + 2\alpha x + \alpha^2 + \beta^2 = 0$, by which all the terms containing this quantity disappear, and the equation is reduced

Inverse Method.

to $\frac{V}{Q} = Ax + B$; and here V and Q are functions of the particular value of x, which satisfies the above-mentioned equation. As in the last case, we shall have an equation of the form $r + s\sqrt{-1} = r' + s'\sqrt{-1}$, r and s being composed of constants and the indeterminate quantities A, B; and these last will be found from the equations

$$r = r', \quad s = s'.$$

We now differentiate the preceding equation, and, after omitting the terms in the result that contain $x^2 + 2\alpha x + \alpha^2 + \beta^2$, have

$$\frac{d\left(\frac{V}{Q}\right)}{dx} = A + (2x + 2\alpha)(Cx + D).$$

By substituting in this expression the imaginary value of x, which satisfies the equation $x^2 + 2\alpha x + \alpha^2 + \beta^2 = 0$, and putting the real and imaginary terms on each side equal, two equations will be obtained which determine C and D.

As an example, let the fraction be $\frac{x^3 - 2x^2 + x - 3}{(x^2 - 2x + 2)^2}$.

We assume it

$$= \frac{Ax + B}{(x^2 - 2x + 2)^2} + \frac{Cx + D}{x^2 - 2x + 2}.$$

By reducing to a common denominator, we find

$$x^3 - 2x^2 + x - 3 = Ax + B + (Cx + D)(x^2 - 2x + 2),$$

one of the roots of the equation $x^2 - 2x + 2 = 0$ is $x = 1 + \sqrt{-1}$; this being substituted for x, the equation, becomes

$$-4 - \sqrt{-1} = A + B + A\sqrt{-1}.$$

Hence, to determine A and B, we have $A + B = -4$, and $A = -1$; therefore $B = -3$. Substituting the values of A and B, and transposing, we have

$$x^3 - 2x^2 + 2x = (Cx + D)(x^2 - 2x + 2);$$

and, taking the differentials, and dividing by dx,

$$3x^2 - 4x + 2 = (Cx + D)(2x - 2) +, \&c.$$

By again substituting $1 + \sqrt{-1}$ for x, this equation becomes

$$-2 + 2\sqrt{-1} = -2C + 2(C + D)\sqrt{-1};$$

hence $C = 1$, $D = 0$, and the proposed fraction is equivalent to

$$-\frac{x + 3}{(x^2 - 2x + 2)^2} + \frac{x}{x^2 - 2x + 2}.$$

There is an extensive class of differentials, rational fractions, in which the denominator has the form $x^{2n} \pm 2x^n \cos \alpha + 1$; also of this form, $x^n \pm 1$. How these functions may be resolved into factors of the first and second degrees has been explained in ALGEBRA, art. 274–278. This resolution being effected, the integration may be performed as has been explained.

Integrals of Irrational Fractions.

123. When a differential involves irrational functions, if by any means these can be transformed into others entirely rational, their integration may be effected by the rules already explained.

For example, let the differential be

$$\frac{(1 + \sqrt{x} - \sqrt[3]{x^2})\,dx}{1 + \sqrt[3]{x}}$$

It is evident, that making $x = z^6$, all the extractions indicated by the radical signs may be effected; and since $dx = 6z^5dz$, the differential is transformed to

$$\frac{6z^5dz(1 + z^3 - z^4)}{1 + z^2};$$

and by actually dividing the numerator by the denominator, this last may be expressed thus,

$$-6(z^7 - z^6 - z^5 + z^4 - z^2 + 1)\,dz - \frac{6dz}{1 + z^2},$$

whose integral is

$$-6\left(\frac{z^8}{8} - \frac{z^7}{7} - \frac{z^6}{6} + \frac{z^5}{5} - \frac{z^3}{3} + z - \tan^{-1} z\right) + \text{const.}$$

By replacing the value of z, viz. $x^{\frac{1}{6}}$, the integral may be expressed in terms of x.

124. We shall now consider those irrational functions which include the radical $\sqrt{a + bx + cx^2}$ only, and which appear under one or other of the two forms,

$$Pdx\sqrt{a + bx + cx^2}, \quad \frac{Pdx}{\sqrt{a + bx + cx^2}},$$

where P denotes any rational function of x. These may, however, be included in one; for if the first be multiplied by the radical, and the same quantity written under it as a denominator, it becomes

$$\frac{P(a + bx + cx^2)dx}{\sqrt{a + bx + c^2}},$$

an expression of the same kind as the second.

We begin with the simple form, $\frac{dx}{\sqrt{a + bx + cx^2}}$, which, however, has two cases, according as the sign of c in the denominator is positive or negative.

125. I. To integrate the differential $\frac{dx}{\sqrt{a + bx + cx^2}}$.

Assume $\sqrt{a + bx + cx^2} = py + \frac{q}{y}$ ....(1)

Here p and q are indeterminate constant quantities, to which such values are to be given as shall serve to transform the proposed differential into another that may be a rational fraction; we have now

$$a + bx + cx^2 = p^2y^2 + 2pq + \frac{q^2}{y^2}.$$

To make the left-hand side of this equation a perfect square, we transpose its first term, then multiply both sides by c, and add $\frac{b^2}{4}$ to each side of the result; it then becomes

$$\frac{b^2}{4} + bcx + c^2x^2 = c\left(p^2y^2 + 2pq - a + \frac{b^2}{4c} + \frac{q^2}{y^2}\right).$$

The second side will also become a square if we make

$$2pq - a + \frac{b^2}{4c} = -2pq,$$

$$\text{or } 4pq = \frac{4ac - b^2}{4c},$$

which is evidently always a possible assumption; by this, the equation becomes

$$\frac{b^2}{4} + bcx + c^2x^2 = c\left(p^2y^2 - 2pq + \frac{q^2}{y^2}\right);$$

and hence, by taking the square roots,

$$\frac{b}{2} + cx = \sqrt{c}\left(py - \frac{q}{y}\right) \text{........................(2)}$$

From this, by differentiation, we obtain

$$\sqrt{c}\,dx = \frac{dy}{y}\left(py + \frac{q}{y}\right) = \frac{dy}{y}\sqrt{a + bx + cx^2};$$

and hence,

$$\frac{dx}{\sqrt{a + bx + cx^2}} = \frac{1}{\sqrt{c}}\frac{dy}{y} \text{.....................(3)}$$

Inverse Method.

Dividing now both sides of equation (2) by $\sqrt{c}$, and adding the results to equation (1), we get

$$\frac{b}{2\sqrt{c}}+x\sqrt{c}+\sqrt{a+bx+cx^2}=2py;$$

and, taking the logarithms,

$$\mathrm{l.}\left(\frac{b}{2\sqrt{c}}+x\sqrt{c}+\sqrt{a+bx+cx^2}\right)=\mathrm{l.}\,y+\mathrm{l.}\,(2p)\ldots(4)$$

Now $\mathrm{l.}\,y=\int\frac{dy}{y}+\mathrm{C}$; here, C being any constant whatever, we may suppose it $=\mathrm{C}'-\mathrm{l.}\,(2p)$, where C′ denotes another indeterminate constant; therefore,

$$\mathrm{l.}\,y+\mathrm{l.}\,(2p)=\int\frac{dy}{y}+\mathrm{C}'.$$

By comparing this last equation with (3) and (4), we find

$$\int\frac{dx}{\sqrt{a+bx+cx^2}},$$

$$=\frac{1}{\sqrt{c}}\,\mathrm{l.}\left(\frac{b}{2\sqrt{c}}+x\sqrt{c}+\sqrt{a+bx+cx^2}\right)+\mathrm{C},$$

$$=\frac{1}{\sqrt{c}}\,\mathrm{l.}\left(b+2cx+2\sqrt{c}\sqrt{a+bx+cx^2}\right)+\mathrm{C}.$$

These logarithmic functions differ from each other only by the constant l $(2\sqrt{c}.)$

126. II. To integrate the differential $\frac{dx}{\sqrt{a+bx-cx^2}}$, assume $\sqrt{a+bx-cx^2}=p\sin\varphi$...........(1) p representing here an indeterminate constant, and φ a variable angle. Then

$$a+bx-cx^2=p^2\sin^2\varphi=p^2-p^2\cos^2\varphi;$$

and hence, proceeding as in last article,

$$\frac{b^2}{4}-bcx+c^2x^2=cp^2\cos^2\varphi+\frac{b^2}{4}+ac-p^2c.$$

The left-hand side of the equation is now a complete square, and to make the right also a square, we assume that

$$cp^2=\frac{b^2}{4}+ac,\ \text{or}\ p\sqrt{c}=\frac{\sqrt{b^2+4ac}}{2}\ldots\ldots\ldots(2)$$

and thus obtain

$$\frac{b^2}{4}-bcx+c^2x^2=cp^2\cos^2\varphi,$$

and, taking the square roots,

$$\frac{b}{2}-cx=\sqrt{c}\,p\cos\varphi\ldots\ldots\ldots\ldots\ldots(3)$$

and hence, differentiating, and dividing by $\sqrt{c}$,

$$dx=\frac{d\varphi}{\sqrt{c}}p\sin\varphi=\frac{d\varphi}{\sqrt{c}}\sqrt{a+bx-cx^2};$$

and hence,

$$\frac{dx}{\sqrt{a+bx-cx^2}}=\frac{1}{\sqrt{c}}d\varphi.$$

Taking now the integral, we have

$$\int\frac{dx}{\sqrt{a+bx-cx^2}}=\frac{1}{\sqrt{c}}\varphi+\text{const.}$$

To determine φ, we have, (3) and (2),

$$\cos\varphi=\frac{b-2cx}{2\sqrt{c}\,p}=\frac{b-2cx}{\sqrt{b^2+4ac}}.$$

Therefore,

$$\int\frac{dx}{\sqrt{a+bx-cx^2}}=\frac{1}{\sqrt{c}}\cos^{-1}\frac{b-2cx}{\sqrt{b^2+4ac}}+\mathrm{C}.$$

We have also

$$\int\frac{dx}{\sqrt{a+bx-cx^2}}=\frac{1}{\sqrt{c}}\sin^{-1}\frac{2cx-b}{\sqrt{b^2+4ac}}+\mathrm{C};$$

for the angle whose cosine is any number v differs from the angle whose sine is $-v$ by a right angle, which is a constant, and therefore the differentials of these angles will be the same expression.

127. We shall now integrate the formula

$$\frac{x^n dx}{\sqrt{a+bx+cx^2}},$$

n being any whole number. We put

$$\mathrm{X}=\sqrt{a+bx+cx^2},\ y=x^m\sqrt{a+bx+cx^2}=x^m\mathrm{X},$$

then $y^2=ax^{2m}+bx^{2m+1}+cx^{2m+2}$,

and differentiating, we have $2ydy=$

$$(2max^{2m-1}+(2m+1)bx^{2m}+(2m+2)cx^{2m+1})dx;$$

and hence, dividing by $y=x^m\mathrm{X}$,

$$2dy=2ma\frac{x^{m-1}dx}{\mathrm{X}}+(2m+1)b\frac{x^m dx}{\mathrm{X}}$$

$$+(2m+2)c\frac{x^{m+1}dx}{\mathrm{X}}.$$

Let us now make $m+1=n$, and therefore $m=n-1$, $m-1=n-2$, $2m=2n-2$, $2m+1=2n-1$, $2m+2=2n$; thus we obtain

$$2dy=(2n-2)a\frac{x^{n-2}dx}{\mathrm{X}}+(2n-1)b\frac{x^{n-1}dx}{\mathrm{X}}$$

$$+2nc\frac{x^n dx}{\mathrm{X}};$$

and hence, by proper arrangement of the terms,

$$\frac{x^n dx}{\mathrm{X}}=\frac{dy}{nc}-\frac{2n-1}{2n}\cdot\frac{b}{c}\cdot\frac{x^{n-1}dx}{\mathrm{X}}-\frac{n-1}{n}\cdot\frac{a}{c}\cdot\frac{x^{n-2}dx}{\mathrm{X}};$$

and, by integration, and putting for y and X the functions they represent, we have

$$\int\frac{x^n dx}{\sqrt{a+bx+cx^2}}=\frac{1}{nc}x^{n-1}\sqrt{a+bx+cx^2}$$

$$-\frac{2n-1}{2n}\cdot\frac{b}{c}\int\frac{x^{n-1}dx}{\sqrt{a+bx+cx^2}}$$

$$-\frac{n-1}{n}\cdot\frac{a}{c}\int\frac{x^{n-2}dx}{\sqrt{a+bx+cx^2}}.$$

The proposed integral is now expressed by an algebraic function, and two other integrals of the same form, but in which the exponents of x are of lower degrees. We have found its value (art. 125, 126) when $n=0$, a case to which the formula just found does not apply, because then, n entering into the denominators of the fractions, they become infinite. When $n=1$, the last of the two integrals in the second side of the equation vanishes, because its coefficient $=0$, and we have

$$\int\frac{xdx}{\sqrt{a+bx+cx^2}}=\frac{1}{c}\sqrt{a+bx+cx^2}$$

$$-\frac{b}{2c}\int\frac{dx}{\sqrt{a+bx+cx^2}}.$$

Knowing now the integrals in the cases of $n=0$ and $n=1$, the preceding general formula gives it in the case of $n=2$; and in the case of $n=3$, it is found from the cases of $n=1$ and $n=2$; and so on to any extent, supposing n to be a positive number.

128. When n is negative, the formula will be better under another form. Writing $-n$ instead of $+n$, and arranging the terms of the result anew, we have

Inverse Method.

$$\int\frac{dx}{x^n\sqrt{a+bx+cx^2}}=\frac{-1}{(n-1)a}\cdot\frac{\sqrt{a+bx+cx^2}}{x^{n-1}}$$
$$-\frac{2n-3}{2n-2}\cdot\frac{b}{a}\int\frac{dx}{x^{n-1}\sqrt{a+bx+cx^2}}$$
$$-\frac{n-2}{n-1}\cdot\frac{c}{a}\int\frac{dx}{x^{n-2}\sqrt{a+bx+cx^2}}.$$

In this formula, n is understood to be positive.

129. This formula of transformation will not apply to the case of $n=1$, because then the fractions which have $n-1$ in the denominator become infinite. It is therefore necessary to investigate the integral of $\frac{dx}{x\sqrt{a+bx+cx^2}}$ separately. Let $x=\frac{1}{y}$; then $\frac{dx}{x}=\frac{-dy}{y}$, and

$$\frac{dx}{x\sqrt{a+bx+cx^2}}=\frac{-dy}{\sqrt{c+by+ay^2}}.$$

This transformed differential has two cases, according as a is positive or negative; when a is positive, the integral is, by article 125,

$$-\frac{1}{\sqrt{a}}\,\mathrm{l.}\,(b+2ay+2\sqrt{a}\,\sqrt{c+by+ay^2})+\mathrm{C}.$$

We are at liberty to give the radical $\sqrt{a}$ either the sign $+$ or the sign $-$; therefore, giving it the latter, the integral is

$$\frac{1}{\sqrt{a}}\,\mathrm{l.}\,(b+2ay-2\sqrt{a}\,\sqrt{c+by+ay^2})+\mathrm{C};$$

and hence, substituting for y its equivalent $\frac{1}{x}$, we have

$$\int\frac{dx}{x\sqrt{a+bx+cx^2}}$$
$$=\frac{1}{\sqrt{a}}\,\mathrm{l.}\,\frac{2a+bx-2\sqrt{a}\,\sqrt{a+bx+cx^2}}{x}+\mathrm{C};$$

observing, as above stated, that the radical $\sqrt{a}$ may have the sign $+$ and also the sign $-$.

In the second case we have

$$\frac{dx}{x\sqrt{-a+bx+cx^2}}=\frac{-dy}{\sqrt{c+by-ay^2}}.$$

Now, by art. 126,

$$\int\frac{-dy}{\sqrt{c+by-a^2y^2}}=-\frac{1}{\sqrt{a}}\sin^{-1}\frac{2ay-b}{\sqrt{b^2+4ac}}+\mathrm{C}$$
$$=\frac{1}{\sqrt{a}}\cos^{-1}\frac{2ay-b}{\sqrt{b^2+4ac}}+\mathrm{C}.$$

Therefore, putting $\frac{1}{x}$ instead of y,

$$\int\frac{dx}{x\sqrt{-a+bx+cx^2}}=\frac{1}{\sqrt{a}}\cos^{-1}\frac{2a-bx}{x\sqrt{b^2+4ac}}+\mathrm{C}.$$

130. The formulæ investigated from articles 125 to 128 serve for the integration of innumerable differentials. Thus, from art. 125 we have

$$\int\frac{dx}{\sqrt{a+x^2}}=\mathrm{l.}\,(x+\sqrt{a+x^2})+\mathrm{C}$$

$$\int\frac{dx}{\sqrt{bx+x^2}}=\mathrm{l.}\,(\tfrac{1}{2}b+x+\sqrt{bx+x^2})+\mathrm{C};$$

and, from the first formula of art. 129

$$\int\frac{adx}{x\sqrt{a^2+cx^2}}=\mathrm{l.}\,\frac{2a^2-2a\sqrt{a^2+cx^2}}{x}+\mathrm{C}$$

$$=\mathrm{l.}\,\frac{a-\sqrt{a^2+cx^2}}{x}+\mathrm{C}.$$

The second of these integrals is obtained from the first by passing l. $(2a)$ into the arbitrary constant C. It may yet have another form; for

$$\int\frac{2adx}{x\sqrt{a^2+cx^2}}=\mathrm{l.}\,\frac{(a-\sqrt{a^2+cx^2})}{-cx^2}+\mathrm{C}.$$

Now $-cx^2=(a+\sqrt{a^2+cx^2})(a-\sqrt{a^2+cx^2})$; therefore, substituting and reducing,

$$\int\frac{adx}{x\sqrt{a^2+cx^2}}=\tfrac{1}{2}\,\mathrm{l.}\,\frac{a-\sqrt{a^2+cx^2}}{a+\sqrt{a^2+cx^2}}+\mathrm{C}.$$

This example shows that the integral is much modified by the arbitrary constant which enters it.

131. Corresponding to these logarithmic integrals there is a set of similar integrals which are expressed by angles or arcs of a circle. Thus we have, art. 126,

$$\int\frac{dx}{\sqrt{a^2-x^2}}=\sin^{-1}\frac{x}{a}+\mathrm{C},$$
$$\int\frac{dx}{\sqrt{ax-x^2}}=\cos^{-1}\left(1-2\frac{x}{a}\right)+\mathrm{C},$$

and by formula 2 of art. 129,

$$\frac{adx}{x\sqrt{x^2-a^2}}=\sec^{-1}\frac{x}{a}+\mathrm{C}=\cos^{-1}\frac{a}{x}+\mathrm{C}.$$

132. As an example of the way of proceeding in the integration of a differential which involves radical quantities, let it be proposed to integrate the differential

$$\frac{dx}{x}\sqrt{\frac{a^2-x^2}{x^2-b^2}}.$$

By an obvious transformation, we find

$$\frac{dx}{x}\sqrt{\frac{a^2-x^2}{x^2-b^2}}=\frac{a^2dx}{x\sqrt{\{(a^2-x^2)(x^2-b^2)\}}}$$
$$-\frac{xdx}{\sqrt{\{(a^2-x^2)(x^2-b^2)\}}}.$$

The first of these differentials may be otherwise expressed thus,

$$-\frac{a}{b}\,\frac{\frac{1}{x}\,d\left(\frac{1}{x}\right)}{\sqrt{\left\{\left(\frac{1}{a^2}-\frac{1}{x^2}\right)\left(\frac{1}{x^2}-\frac{1}{b^2}\right)\right\}}}.$$

Therefore we have

$$\frac{dx}{x}\sqrt{\frac{a^2-x^2}{x^2-b^2}}=\frac{-xdx}{\sqrt{\{(a^2-x^2)(x^2-b^2)\}}}$$
$$-\frac{a}{b}\,\frac{\frac{1}{x}\,d\left(\frac{1}{x}\right)}{\sqrt{\left\{\left(\frac{1}{a^2}-\frac{1}{x^2}\right)\left(\frac{1}{x^2}-\frac{1}{b^2}\right)\right\}}},$$

and it is evident that the two differentials have precisely the same form.

To integrate the first of these, let us assume

$$x^2=a^2\cos^2\varphi+b^2\sin^2\varphi;$$
$$\text{then } xdx=(b^2-a^2)\sin\varphi\cos\varphi\,d\varphi,$$
$$a^2-x^2=(a^2-b^2)\sin^2\varphi\ldots\ldots\ldots\ldots(1)$$
$$x^2-b^2=(a^2-b^2)\cos^2\varphi\ldots\ldots\ldots\ldots(2)$$
$$\frac{-xdx}{\sqrt{\{(a^2-x^2)(x^2-b^2)\}}}=\frac{(a^2-b^2)\cos\varphi\sin\varphi\,d\varphi}{(a^2-b^2)\cos\varphi\sin\varphi}=d\varphi,$$

Exactly in the same way, if we make

$$\frac{1}{x^2}=\frac{1}{a^2}\cos^2\psi+\frac{1}{b^2}\sin^2\psi,$$

Inverse Method.

we get

$$\frac{1}{x}d\left(\frac{1}{x}\right)=\left(\frac{1}{b^2}-\frac{1}{a^2}\right)\sin\psi\cos\psi d\psi,$$

$$\frac{1}{a^2}-\frac{1}{x^2}=\left(\frac{1}{a^2}-\frac{1}{b^2}\right)\sin^2\psi\ldots\ldots\ldots\ldots(3)$$

$$\frac{1}{x^2}-\frac{1}{b^2}=\left(\frac{1}{a^2}-\frac{1}{b^2}\right)\cos^2\psi\ldots\ldots\ldots\ldots(4)$$

$$\frac{-\frac{1}{x}d\left(\frac{1}{x}\right)}{\sqrt{\left\{\left(\frac{1}{a^2}-\frac{1}{x^2}\right)\left(\frac{1}{x^2}-\frac{1}{b^2}\right)\right\}}}=\frac{\left(\frac{1}{b^2}-\frac{1}{a^2}\right)\sin\psi\cos\psi d\psi}{\left(\frac{1}{b^2}-\frac{1}{a^2}\right)\sin\psi\cos\psi}=d\psi.$$

On the whole, if φ and ψ be such angles that

$$\cos\varphi=\sqrt{\frac{x^2-b^2}{a^2-b^2}},\quad \cos\psi=\frac{a}{x}\cos\varphi;$$

then

$$\int\frac{dx}{x}\sqrt{\frac{a^2-x^2}{x^2-b^2}}=\varphi+\frac{a}{b}\psi+\text{const.}$$

Integration of Binomial Differentials.

133. These differentials are represented by the formula

$$x^{m-1}dx\,(a+bx^n)^{\frac{p}{q}},$$

whose generality will not be affected by supposing that m and n are whole numbers. The object we propose is to find in what case this differential may be made rational.

We assume $a+bx^n=z^q$, so that $(a+bx^n)^{\frac{p}{q}}=z^p$; we then find

$$x^n=\frac{z^q-a}{b},\quad x^m=\left(\frac{z^q-a}{b}\right)^{\frac{m}{n}},$$

$$x^{m-1}dx=\frac{q}{nb}z^{q-1}\left(\frac{z^q-a}{b}\right)^{\frac{m}{n}-1}dz;$$

and the proposed differential is now transformed into

$$\frac{q}{nb}z^{p+q-1}\,dz\left(\frac{z^q-a}{b}\right)^{\frac{m}{n}-1},$$

an expression which is evidently rational whenever $\frac{m}{n}$ is a whole number.

The differential $x^8dx\,(a+bx^3)^{\frac{p}{q}}$ satisfies this condition, since $m=9$, $n=3$, $\frac{m}{n}=3$, and it is transformed into

$$\frac{q}{3b}z^{p+q-1}\,dz\left(\frac{z^q-a}{b}\right)^2.$$

The differential $x^{m-1}\,dx\,(a+bx^n)^{\frac{p}{q}}$ admits of another form, by making the index of x between the brackets negative, or by dividing the quantity $a+bx^n$ by x^n; then we have

$$x^{m-1}dx\,(a+bx^n)^{\frac{p}{q}}=x^{m-1}dx\,\{(ax^{-n}+b)\,x^n\}^{\frac{p}{q}}$$
$$=x^{m+\frac{np}{q}-1}\,dx\,(ax^{-n}+b)^{\frac{p}{q}};$$

and by the process preceding, the last of these expressions may be made rational, whenever $\dfrac{m+\frac{np}{q}}{n}$ is a whole number; or, what is the same thing, whenever $\frac{m}{n}+\frac{p}{q}$ is an integer.

The differential $x^4\,dx\,(a+bx^3)^{\frac{1}{3}}$ is of this description, since $\frac{m}{n}=\frac{5}{3}$, $\frac{p}{q}=\frac{1}{3}$, $\frac{m}{n}+\frac{p}{q}=\frac{6}{3}=2$.

In applying to the differential

$$x^{m+\frac{np}{q}-1}\,dx\,(ax^{-n}+b)^{\frac{p}{q}},$$

the substitution indicated for the first form of this differential, we shall make $ax^{-n}+b=z^q$, and thence deduce $a+bx^n=x^n z^q$; and if we transform immediately the expression $x^{m-1}\,dx\,(a+bx^n)^{\frac{p}{q}}$ by means of the equation preceding, we shall evidently obtain the same result as if we had at first given it the form

$$x^{m+\frac{np}{q}-1}\,dx(ax^{-n}+b)^{\frac{p}{q}}.$$

134. Since it is not possible to integrate in every case the formula $x^{m-1}\,dx\,(a+bx^n)^{\frac{p}{q}}$, we may try to change it into another more simple, as has been done in integrating a differential (art. 115). We have found that $\int udv=uv-\int vdu$. If therefore we can decompose the differential into two factors, one of which being integrable, may be represented by dv, and the other by u, the integration of the proposed differential will be made to depend on that of vdu, which in some cases will be more simple than the proposed differential. This method, which is at once extensive and elegant, is called *integration by parts.*

For the sake of abridging, we shall write simply p instead of $\frac{p}{q}$, supposing p to represent a fractional number. The formula will then become

$$x^{m-1}\,dx\,(a+bx^n)^p.$$

Among the different ways of resolving this differential into factors, we choose this:

$$x^{m-n}\,x^{n-1}\,dx\,(a+bx^n)^p.$$

One of the factors, $x^{n-1}\,dx\,(a+bx^n)^p$, is integrable, whatever be the value of p (art. 108); representing it therefore by dv, we have

$$v=\frac{(a+bx^n)^{p+1}}{nb\,(p+1)},\text{ and }u=x^{m-n},$$

whence there results

$$\int x^{m-1}dx\,(a+bx^n)^p=\frac{x^{m-n}(a+bx^n)^{p+1}}{nb\,(p+1)},$$
$$-\frac{m-n}{nb\,(p+1)}\int x^{m-n-1}\,dx\,(a+bx^n)^{p+1};$$

but $\int x^{m-n-1}\,dx\,(a+bx^n)^{p+1}$

$$=\int x^{m-n-1}\,dx\,(a+bx^n)^p\,(a+bx^n)=$$
$$a\int x^{m-n-1}\,dx\,(a+bx)^p+$$
$$b\int x^{m-1}\,dx\,(a+bx^n)^p,$$

putting this last in the preceding equation; and collecting the terms containing the integral $\int x^{m-1}dx(a+bx^n)^p$, we obtain, after reduction,

(A.)

$$\int x^{m-1}dx\,(a+bx^n)^p = \frac{x^{m-n}(a+bx^n)^{p+1}}{b\,(pn+m)}$$
$$-\frac{a\,(m-n)}{b\,(pn+m)}.\int x^{m-n-1}dx\,(a+bx^n)^p.$$

It is obvious that since we may reduce the integration of $x^{m-1}dx\,(a+bx^n)^p$ to that of $x^{m-n-1}dx\,(a+bx^n)^p$, we may reduce this last to the integration of $x^{m-2n-1}dx\,(a+bx^n)^p$ by writing $m-n$ in the place of m in equation (A); then, by changing $m-n$ into $m-2n$, we shall be able to determine $\int x^{m-2n-1}dx\,(a+bx^n)^p$ by means of $\int x^{m-3n-1}dx\,(a+bx^n)^p$, and so on.

In general, if r denote the number of reductions, we shall at last come to $\int x^{m-rn-1}dx\,(a+bx^n)^p$, and the last formula will be

$$\int x^{m-(r-1)n-1}dx\,(a+bx^n)^p$$
$$=\frac{x^{m-rn}(a+bx^n)^{p+1}}{b\{pn+m-(r-1)n\}}-$$
$$\frac{a\,(m-rn)}{b\,\{pn+m-(r-1)n\}}\int x^{m-rn-1}dx\,(a+bx^n)^p.$$

It appears from this formula, that if m be a multiple of n, the integration of the proposed formula $x^{m-1}dx\,(a+bx^n)^p$ may be effected in algebraic terms, since the last integral of the transformed expression will be multiplied by $m-rn=0$. This result agrees with that of art. 133.

135. There is another way of reduction by which the exponent of the quantity within the parenthesis may be diminished by an unit; for this purpose it is only necessary to observe that

$$\int x^{m-1}dx(a+bx^n)^p$$
$$=\int x^{m-1}dx(a+bx^n)^{p-1}(a+bx^n)$$
$$=a\int x^{m-1}dx(a+bx^n)^{p-1}$$
$$+\,b\int x^{m+n-1}dx(a+bx^n)^{p-1}.$$

Formula (A), by changing m into $m+n$, and p into $p-1$, gives

$$\int x^{m+n-1}dx(a+bx^n)^{p-1}=$$
$$\frac{x^m(a+bx^n)^p-am\int x^{m-1}dx(a+bx^n)^{p-1}}{b(pn+m)}.$$

Substituting this value in the preceding equation, we have

(B)

$$\int x^{m-1}dx(a+bx^n)^p=\frac{x^m(a+bx^n)^p}{pn+m}$$
$$+\,\frac{pna}{pn+m}\int x^{m-1}dx(a+bx^n)^{p-1}.$$

By this formula we may take away successively from p as many units as it contains; and by its application, along with formula (A), we may make the integral

$$\int x^{m-1}dx(a+bx^n)^p \text{ depend on}$$

$\int x^{m-rn-1}dx(a+bx^n)^{p-s}$, rn being the greatest multiple of m contained in $m-1$, and s the greatest whole number contained in p.

The integral $\int x^7dx(a+bx^3)^{\frac{5}{2}}$, for example, may be reduced by formula (A) successively to

$$\int x^4dx(a+bx^3)^{\frac{5}{2}},\ \int xdx(a+bx^3)^{\frac{5}{2}};$$

and by formula (B), $\int xdx(a+bx^3)^{\frac{5}{2}}$ is reduced to

$\int xdx(a+bx^3)^{\frac{3}{2}}$, and that again to $\int xdx(a+bx^3)^{\frac{1}{2}}$.

136. It is evident that if m and n were negative, the formulæ (A) and (B) would not accomplish the purpose for which they have been investigated; they would then increase the exponent of x without the parenthesis, as well as that of the parenthesis itself; but by reversing them we shall find others suited to the case in question. From formula (A) we deduce

$$\int x^{m-n-1}dx(a+bx^n)^p=\frac{x^{m-n}(a+bx^n)^{p+1}}{a(m-n)},$$
$$-\frac{b(m+np)}{a(m-n)}\int x^{m-1}dx(a+bx^n)^p.$$

In this expression, substitute $m+n$ in place of m and it becomes

(C)

$$\int x^{m-1}dx(a+bx^n)^p=\frac{x^m(a+bx^n)^{p+1}}{am}$$
$$-\frac{b(m+n+np)}{am}\int x^{m+n-1}dx(a+bx^n)^p.$$

This formula diminishes the exponent without the parenthesis, since $m+n-1$ becomes $-m+n-1$ when $-m$ is put instead of $+m$.

To reverse the formula (B), we take

$$\int x^{m-1}dx(a+bx^n)^{p-1}=-\frac{x^m(a+bx^n)^p}{pna}$$
$$+\frac{m+np}{pna}\int x^{m-1}dx(a+bx^n)^p;$$

then we write $p+1$ instead of p, and thus find formula

(D)

$$\int x^{m-1}dx(a+bx^n)^p=-\frac{x^m(a+bx^n)^{p+1}}{na(p+1)}$$
$$+\frac{m+n+np}{na(p+1)}\int x^{m-1}dx(a+bx^n)^{p+1}.$$

This formula answers the proposed purpose, since $p+1$ becomes $-p+1$, when p is negative.

137. Let the formula be $\int\frac{x^{m-1}dx}{\sqrt{1-x^2}}$, where m is a whole positive number. Making $a=1$, $b=-1$, $n=2$, $p=-\frac{1}{2}$, we find

$$\int\frac{x^{m-1}dx}{\sqrt{1-x^2}}=-\frac{x^{m-2}\sqrt{1-x^2}}{m-1}+\frac{m-2}{m-1}\int\frac{x^{m-3}dx}{\sqrt{1-x^2}}.$$

Writing m in place of $m-1$, we have

$$\int\frac{x^m dx}{\sqrt{1-x^2}}=-\frac{x^{m-1}\sqrt{1-x^2}}{m}+\frac{m-1}{m}\int\frac{x^{m-2}\,dx}{\sqrt{1-x^2}}.$$

If we give to m successive different values, beginning with the uneven numbers, we have

$$\int\frac{x\,dx}{\sqrt{1-x^2}}=-\sqrt{1-x^2}+\text{const.}$$

$$\int\frac{x^3dx}{\sqrt{1-x^2}}=-\tfrac{1}{3}x^2\sqrt{1-x^2}+\tfrac{2}{3}\int\frac{x\,dx}{\sqrt{1-x^2}},$$

$$\int\frac{x^5dx}{\sqrt{1-x^2}}=-\tfrac{1}{5}x^4\sqrt{1-x^2}+\tfrac{4}{5}\int\frac{x^3dx}{\sqrt{1-x^2}},$$

$$\int\frac{x^7dx}{\sqrt{1-x^2}}=-\tfrac{1}{7}x^6\sqrt{1-x^2}+\tfrac{6}{7}\,\frac{x^5dx}{\sqrt{1-x^2}},$$

&c.

and hence we deduce

$$\int\frac{x^3dx}{\sqrt{1-x^2}}=-\left(\tfrac{1}{3}x^2+\frac{1.2}{1.3}\right)\sqrt{1-x^2},$$

$$\int\frac{x^5dx}{\sqrt{1-x^2}}=-\left(\tfrac{1}{5}x^4+\frac{1.4}{3.5}x^2+\frac{1.2.4}{1.3.5}\right)\sqrt{1-x^2},$$

$$\int\frac{x^7dx}{\sqrt{1-x^2}}=-\left(\tfrac{1}{7}x^6+\frac{1.6}{5.7}x^4+\frac{1.4.6}{3.5.7}x^2\right.$$
$$\left.+\frac{1.2.4.6}{1.3.5.7}\right)\sqrt{1-x^2},$$

&c.

The law of formation of the integrals is evident; an arbitrary constant is to be annexed to each.

Let us now consider the even values of m. Supposing $m=2, 4, 6$, &c. we have

$$\int\frac{x^2dx}{\sqrt{1-x^2}}=-\tfrac{1}{2}x\sqrt{1-x^2}+\tfrac{1}{2}\int\frac{dx}{\sqrt{1-x^2}},$$

$$\int\frac{x^4dx}{\sqrt{1-x^4}}=-\tfrac{1}{4}x^3\sqrt{1-x^2}+\tfrac{3}{4}\int\frac{x^2dx}{\sqrt{1-x^2}},$$

$$\int\frac{x^6dx}{\sqrt{1-x^2}}=-\tfrac{1}{6}x^5\sqrt{1-x^2}+\tfrac{5}{6}\int\frac{x^4dx}{\sqrt{1-x^2}}.$$

&c.

Here all the integrals depend on

$$\int\frac{dx}{\sqrt{1-x^2}}=\sin^{-1}x+\text{const. (art. 23.)}$$

Let us call A the arc whose sine is x, and we have

$$\int\frac{dx}{\sqrt{1-x^2}}=\text{A}+\text{const.}$$

$$\int\frac{x^2dx}{\sqrt{1-x^2}}=-\tfrac{1}{2}x\sqrt{1-x^2}+\tfrac{1}{2}\text{A}+\text{const.}$$

$$\int\frac{x^4dx}{\sqrt{1-x^2}}=-\left(\tfrac{1}{4}x^3+\frac{1.3}{2.4}x\right)\sqrt{1-x^3}$$
$$+\frac{1.3}{2.4}\text{A}+\text{const.}$$

$$\int\frac{x^6dx}{\sqrt{1-x^2}}=-\left(\tfrac{1}{6}x^5+\frac{1.5}{4.6}x^3+\frac{1.3.5}{2.4.6}x\right)\sqrt{1-x^2}$$
$$+\frac{1.3.5}{2.4.6}\text{A}+\text{const.}$$

138. Let us now consider the formulæ which answer to the case of m negative; then by formula (C) art. 136,

$$\int\frac{x^{-m-1}dx}{\sqrt{1-x^2}}=-\frac{x^{-m}\sqrt{1-x^2}}{m}$$
$$+\frac{m-1}{m}\int\frac{x^{-m+1}dx}{\sqrt{1-x^2}}.$$

Writing $-m$ instead of $-m-1$, this becomes

$$\int\frac{dx}{x^m\sqrt{1-x^2}}=\frac{-\sqrt{1-x^2}}{(m-1)x^{m-1}}$$
$$+\frac{m-2}{m-1}\int\frac{dx}{x^{m-2}\sqrt{1-x^2}}.$$

We cannot make $m=1$, because that value would make the denominator *zero* and the co-efficient infinite. We have already found the integral in this case, viz.

$$\int\frac{dx}{x\sqrt{1-x^2}}=+\,\text{l.}\frac{1-\sqrt{1-x^2}}{x}+\text{const. (art. 130).}$$

Proceeding now, making $m=3$, $m=5$, &c. we have

$$\int\frac{dx}{x^3\sqrt{1-x^2}}=-\frac{\sqrt{1-x^2}}{2x^2}+\tfrac{1}{2}\int\frac{dx}{x\sqrt{1-x^2}},$$

$$\int\frac{dx}{x^5\sqrt{1-x^2}}=-\frac{\sqrt{1-x^2}}{4x^4}+\tfrac{3}{4}\int\frac{dx}{x^3\sqrt{1-x^2}},$$

$$\int\frac{dx}{x^7\sqrt{1-x^2}}=-\frac{\sqrt{1-x^2}}{6x^6}+\tfrac{5}{6}\int\frac{dx}{x^5\sqrt{1-x^2}}.$$

&c.

Making $m=2$, $m=4$, $m=6$, &c. we find

$$\int\frac{dx}{x^2\sqrt{1-x^2}}=-\frac{\sqrt{1-x^2}}{x}+\text{const.}$$

$$\frac{dx}{x^4\sqrt{1-x^4}}=-\frac{\sqrt{1-x^2}}{3x^3}+\tfrac{2}{3}\int\frac{dx}{x^2\sqrt{1-x^2}},$$

$$\frac{dx}{x^6\sqrt{1-x^6}}=-\frac{\sqrt{1-x^2}}{5x^5}+\tfrac{4}{5}\int\frac{dx}{x^4\sqrt{1-x^2}},$$

&c.

From these two series of equations we deduce, as in the former article, a series of differentials integrated by logarithms, and another by algebraic formulæ.

Integration by Series.

139. The integral $\int \text{X}\,dx$ is easily found when the function X is expanded into a series, because then we have only to integrate a series of single terms in succession, to which the rule of art. 104 immediately applies.

Thus, let $\text{X}=\text{A}x^m+\text{B}x^{m+n}+\text{C}x^{m+2n}+\text{D}x^{m+3n}+$ &c. If both members of this equation be multiplied by dx, and each term be separately integrated, we have

$$\int\text{X}\,dx=\frac{\text{A}x^{m+1}}{m+1}+\frac{\text{B}x^{m+n+1}}{m+n+1}+\frac{\text{C}x^{m+2n+1}}{m+2n+1}+\text{\&c.}+c.$$

If in the expansion of X any term of the form $\frac{\text{E}}{x}$ occur, the integral corresponding to that term will be E l. x (art. 20). We shall now give particular examples.

Ex. 1. To integrate $\frac{dx}{a+x}$ by a series.

We know that the integral comprehends in it Napier's logarithm of $a+x$ (art. 20). Now, by division,

$$\frac{1}{a+x}=\frac{1}{a}-\frac{x}{a^2}+\frac{x^2}{a^3}-\frac{x^3}{a^4}+\frac{x^5}{a^6}-\text{\&c.}$$

Therefore, multiplying by dx, and integrating,

$$\int\frac{dx}{a+x}=\frac{x}{a}-\frac{x^2}{2a^2}+\frac{x^3}{3a^3}-\frac{x^4}{4a^4}+\text{\&c.}+\text{C.}$$

This series expresses the general integral, without any regard to its particular application. If, however, we consider it as expressing l. $(a+x)$, then we have

Inverse Method.

$$\text{l.}\,(a+x)=\frac{x}{a}-\frac{x^2}{2a^2}+\frac{x^3}{3a^3}-\frac{x^4}{4a^4}+\&c.+C.$$

The constant quantity C is now no longer indeterminate; it must have such a value as satisfies this equation whatever be the value of x. If we make $x=0$, then all the terms of the series vanish, and we have $\text{l.}\,a=C$.

Thus the value of C is determined, and we have

$$\text{l.}\,(a+x)=\text{l.}\,a+\frac{x}{a}-\frac{x^2}{2a^2}+\frac{x^3}{3a^3}-\&c.$$

This result agrees with what we found (art. 86).

Ex. 2. To integrate $\frac{dx}{1+x^2}$ by a series. By division,

$$\frac{1}{1+x^2}=1-x^2+x^4-x^6+\&c.$$

Multiplying now both sides of this equation by dx, and integrating, we have

$$\int\frac{dx}{1+x^2}=x-\frac{x^3}{3}+\frac{x^5}{5}-\frac{x^7}{7}+\&c.+C.$$

As a formula purely analytical, the constant C must be regarded as indeterminate. We know, however, that $\frac{dx}{1+x^2}$ is the integral of an arc of which x is the tangent, the radius being unity (art. 22, Ex. 3). Therefore, if we mean to express $\tan^{-1}x$ by a series, then

$$\tan^{-1}x=x-\frac{x^3}{3}+\frac{x^5}{5}-\frac{x^7}{7}+\&c.+C.$$

The constant C has now a precise value, and it may be found by giving any corresponding known values to $\tan^{-1}x$ and x. Now we know that when $\tan^{-1}x=0$, then $x=0$. Therefore, considering that when all the terms in the series vanish, we have $0=0+C$; thus it appears that $C=0$.

Ex. 3. In the last example, the integral of $\frac{dx}{1+x^2}$ was expressed by a series of terms formed from the ascending powers of x. We may, however, express that integral by a descending series. By division

$$\frac{1}{x^2+1}=\frac{1}{x^2}-\frac{1}{x^4}+\frac{1}{x^6}-\&c.$$

And $\int\frac{dx}{x^2+1}=-\frac{1}{x}+\frac{1}{3x^3}-\frac{1}{5x^5}+\&c.+C.$

If we now regard the integral as the angle or arc whose tangent is x, we have

$$\tan^{-1}x=\frac{-1}{x}+\frac{1}{3x^3}-\frac{1}{5x^5}+\&c.+C.$$

The value of C cannot now be found by making $x=0$, because then the arc $=0$, and the substitution of $x=0$ makes all the terms of the series infinite. If we suppose the arc to be a quadrant $=\frac{\pi}{2}$, then x is infinite, and the terms of the series are each $=0$; by this assumption, $\frac{1}{2}\pi=C$. We have now

$$\tan^{-1}x=\tfrac{1}{2}\pi-\frac{1}{x}+\frac{1}{3x^3}-\frac{1}{5x^5}+\&c.$$

Ex. 4. The differential of the arc whose sine is x is $\frac{dx}{\sqrt{1-x^2}}$. It is proposed to integrate this differential by a series.

By the binomial theorem, $\frac{1}{\sqrt{1-x^2}}=(1-x^2)^{-\frac{1}{2}}=$

$$1+\tfrac{1}{2}x^2+\frac{1.3}{2.4}x^4+\frac{1.3.5}{2.4.6}x^6+\frac{1.3.5.7}{2.4.6.8}x^8+\&c.$$

Hence we have $\sin^{-1}x=\int\frac{dx}{\sqrt{1-x^2}}=$

$$x+\frac{1.x^3}{2.3}+\frac{1.3x^5}{2.4.5}+\frac{1.3.5x^7}{2.4.6.7}+\&c.$$

When the arc $=0$, then the sine $=0$; therefore both sides of this equation vanish together, and no constant is wanted to adjust it to equality.

140. The object of integration by series being to obtain approximate values of the integrals when they cannot be found accurately, it is important to have several series, so that we may be able to choose one convergent for a proposed value of x. Ascending series, or those which proceed by positive and increasing powers of x, do not converge sufficiently unless x be a small fraction, as happens with the series of Ex. 2; whilst those which proceed by the negative powers of x, or descending series, converge only so as to be of use when x is a large number.

141. In having recourse to series, it is sufficient to find one, of which the terms are separately integrable, although each may not have the form $Ax^{\frac{m}{n}}dx$; they may have any form, the integral of which can be expressed by an algebraic quantity, or a logarithm, or an arc of a circle; or, in short, any function, the numerical value of which is most readily obtained, provided always that the convergency be such as to admit of the sum of all the terms which are not taken in being rejected, because of its smallness in comparison to the sum of the terms taken in.

In the application of the calculus recourse is only to be had to series as a last resource, when the integral, from its nature, cannot be found in finite terms, or by logarithms or arcs of a circle, which in fact are the sums of infinite series. Indeed it would be very convenient to have various other tables, ready computed, of the value of a function corresponding to given successive values of the variable. The labour of their computation, their necessary great extent, and the infrequency of their use, have hitherto limited this valuable aid in calculation to a table of Napier's Logarithms, in addition to the Trigonometrical Tables.

Integration of Logarithmic Functions.

142. Let it be required to integrate $Pdx\,(\text{l.}\,x)^n$, that is, the nth power of Napier's logarithm of x multiplied by Pdx, P being an algebraic function of x. Here we apply the formula $\int udv=uv-\int vdu$; and making $u=(\text{l.}\,x)^n$, from which we find $du=n\,(\text{l.}\,x)^{n-1}\frac{dx}{x}$, also $dv=Pdx$, we have, making in order to abridge $\int Pdx=N$,

$$\int Pdx\,(\text{l.}x)^n=N\,(\text{l.}\,x)^n-n\int\frac{dx}{x}\,(\text{l.}\,x)^{n-1}N.$$

If now we represent the integral $\int\frac{dx}{x}N$ by M, we shall have

$$\int\frac{dx}{x}N(\text{l.}x)^{n-1}=M\,(\text{l.}x)^{n-1}-(n-1)\int\frac{dx}{x}(\text{l.}\,x)^{n-2}M.$$

By this reduction the proposed integral is made to depend on another of the same kind, in which the exponent of the logarithm is an unit less. Thus, if $P=x^m$, we have

$$\int x^m dx\,(\text{l.}\,x)^n=\frac{x^{m+1}}{m+1}(\text{l.}\,x)^n-\frac{n}{m+1}\int(\text{l.}x)^{n-1}x^m dx.$$

Inverse Method.

By applying the formula to this last integral, and again to the result, we find $\int x^m dx\,(\mathrm{l}.\,x)^n =$

$$x^{m+1}\left\{\frac{(\mathrm{l}.\,x)^n}{m+1}-\frac{n(\mathrm{l}.\,x)^{n-1}}{(m+1)^2}+\frac{n(n-1)(\mathrm{l}.\,x)^{n-2}}{(m+1)^3}-\&c.\right\}+\mathrm{C}.$$

It is evident that this will always terminate when n is a whole number.

143. If n be a whole negative number, we must apply the formula $\int udv = uv - \int vdu$ so as to increase the exponent of the logarithm. Thus in the differential

$$\frac{\mathrm{P}dx}{(\mathrm{l}.\,x)^n}=\frac{\mathrm{P}x}{-n+1}\cdot(-n+1)(\mathrm{l}.\,x)^{-n}\,\frac{dx}{x},$$

we make $\mathrm{P}x = u$, and $(\mathrm{l}.\,x)^{-n}\dfrac{dx}{x} = dv$, by which $\dfrac{(\mathrm{l}.\,x)^{-n+1}}{-n+1} = v$; for then we have $\int\dfrac{\mathrm{P}dx}{(\mathrm{l}.x)^n} =$

$$\frac{\mathrm{P}x}{-n+1}(\mathrm{l}.\,x)^{-n+1}+\frac{1}{n-1}\int(\mathrm{l}.\,x)^{-n+1}\,d(\mathrm{P}x).$$

Let us suppose $\mathrm{P} = x^m$, then this formula becomes

$$\int\frac{x^m dx}{(\mathrm{l}.x)^n}=\frac{-x^{m+1}}{(n-1)(\mathrm{l}.\,x)^{n-1}}+\frac{m+1}{n-1}\int\frac{x^m dx}{(\mathrm{l}.\,x)^{n-1}}.$$

By repetitions of this transformation, we at last make the proposed integral depend on $\int\dfrac{x^m dx}{\mathrm{l}.\,x}$. Now, put $x^{m+1} = z$, then $\mathrm{l}.\,x = \dfrac{\mathrm{l}.\,z}{m+1}$ and $x^m dx = \dfrac{dz}{m+1}$, therefore

$$\frac{x^m dx}{\mathrm{l}.\,x}=\frac{dz}{\mathrm{l}.\,z}.$$

The integral of this last quantity is a transcendental of a peculiar kind, which cannot be otherwise expressed than by infinite series.

Integration of Exponential Functions.

144. It appears from art. 19, that $d(a^x) = \mathrm{l}.(a)\,a^x\,dx$, therefore

$$\int a^x dx = \frac{a^x}{\mathrm{l}.\,a}+\mathrm{C}.$$

And because $dx = \dfrac{d(a^x)}{a^x\,\mathrm{l}.\,a}$; therefore, if V be any algebraic function of a^x, then, putting $a^x = u$, we have $\mathrm{V}dx = \dfrac{\mathrm{V}du}{u\,\mathrm{l}.\,a}$, an expression which, in respect of u, has an algebraic form.

For example, let $\mathrm{V} = \dfrac{a^x}{\sqrt{1+a^{nx}}}$, then,

$$\int\frac{a^x dx}{\sqrt{1+a^{nx}}}=\int\frac{du}{\mathrm{l}.\,a\sqrt{1+u^n}}.$$

The integral of this last expression may be found by rules which have been investigated.

Let z be any function of x, then, e being the number of which Nap. log $= 1$, we have $d(ze^x) = e^x dz + e^x z dx$, therefore

$$\int e^x dx\left(z+\frac{dz}{dx}\right)=ze^x+\mathrm{C}.$$

For example, let $z = x^3 - 1$, then $\dfrac{dz}{dx} = 3x^2$, and

$$\int e^x dx(3x^2+x^3-1)=e^x(x^3-1)+\mathrm{C}.$$

145. In other cases we may have recourse to the method of integration by parts (art. 134). Thus, let the differential be $x^n a^x dx$, then, by the formula $\int udv = uv - \int vdu$, making $u = x^n$, $dv = a^x dx$, we find

$$\int a^x x^n dx=\frac{a^x x^n}{\mathrm{l}.\,a}-\frac{n}{\mathrm{l}.\,a}\int a^x x^{n-1}dx.$$

By treating the differential $a^x x^{n-1}dx$ in the same way, and repeating this as often as necessary, we find $\int a^x x^n dx =$

$$a^x\left\{\frac{x^n}{\mathrm{l}.\,a}-\frac{nx^{n-1}}{(\mathrm{l}.\,a)^2}+\frac{n(n-1)x^{n-2}}{(\mathrm{l}.\,a)^3}-\ldots\pm\frac{1.2.3\ldots n}{(\mathrm{l}.\,a)^{n+1}}\right\}+\mathrm{C}.$$

146. If the exponent n be negative, by following the same method we may increase the exponent of x. Accordingly, from the formula $\int udv = uv - \int vdu$, making $u = a^x$, and $dv = \dfrac{dx}{x^n}$, we find

$$\int\frac{a^x dx}{x^n}=\frac{-a^x}{(n-1)x^{n-1}}+\frac{\mathrm{l}.\,a}{n-1}\int\frac{a^x dx}{x^{n-1}}.$$

By repeating this transformation, we bring the integral $\int\dfrac{a^x dx}{x^n}$ to depend at last on $\int\dfrac{a^x dx}{x}$.

If we make $a^x = z$, then $x\,\mathrm{l}.\,a = \mathrm{l}.\,z$, and $x = \dfrac{\mathrm{l}.\,z}{\mathrm{l}.\,a}$, and $dx = \dfrac{1}{\mathrm{l}.\,a}\dfrac{dz}{z}$; hence $\dfrac{a^x dx}{x} = \dfrac{1}{\mathrm{l}.\,a}\dfrac{dz}{\mathrm{l}.\,z}$, and

$$\int\frac{a^x dx}{x}=\frac{1}{\mathrm{l}.\,a}\int\frac{dz}{\mathrm{l}.\,z}.$$

These two integrals involve the same difficulty, and have greatly exercised the ingenuity of analysts. It appears they can only be integrated by infinite series. See on this subject, Lacroix, *Traité du Calcul Differentiel*, vol. iii. No. 1224.

147. If n be a fraction, either of the preceding methods will apply to reduce the exponent of x to some fraction between 0 and $+ 1$ or $- 1$; and then recourse must be had to the method of infinite series.

Whatever has been done in regard to the integral of $x^n a^x dx$, will apply to $\mathrm{P}a^x dx$, supposing P to be any function of x whatever.

Integration of Angular or Circular Functions.

148. There are several ways of integrating expressions which contain circular or trigonometrical functions of a variable.

Method I.—Let x be an arc whose sine or cosine is z; for example, let $\sin x = z$, then

$$\cos x = \sqrt{1-z^2},\ dx=\frac{dz}{\sqrt{1-z^2}},$$

$$dx\,\sin^m x\,\cos^n x = z^m(1-z^2)^{\frac{n-1}{2}}dz.$$

1. If n be any odd number, then, in the binomial differential, the radical in the transformed expression disappears.

2. If m is an odd number, the exponent of z without the parenthesis, when increased by unity, will be a multiple of z its exponent, within the parenthesis. Thus one of the conditions of art. 133 is satisfied, and the differential may be made rational.

3. If m and n are even numbers, then the second condition of art. 133 will be satisfied, and the differential may be integrated.

As an example, let the differential be $dx \sin^3 x$. This, by making $z = \sin x$, becomes $\frac{z^3\,dz}{\sqrt{1-z^2}}$. Now, by art. 137,

$$\int \frac{z^3\,dz}{\sqrt{1-z^2}} = -\tfrac{1}{3}\cos x\,(2+\sin^2 x) + C.$$

149. Method II.—The powers of the sine or cosine may be transformed into series, of which the terms are sines or cosines of the multiples of the arc; the terms to be integrated will then have the form $dx \cos kx$, $dx \sin kx$. Now

$$\int dx \cos kx = \frac{1}{k}\sin kx + C;$$

$$\int dx \sin kx = -\frac{1}{k}\cos kx + C.$$

Ex. 1. Let the differential be $dx \cos^5 x$. By the calculus of sines (Algebra, 258), $\cos^5 x = \frac{1}{16}(\cos 5x + 5 \cos 3x + 10 \cos x)$; therefore

$\int dx \cos^5 x = \frac{1}{80}\sin 5x + \frac{5}{48}\sin 3x + \frac{5}{8}\sin x + C.$

This method is often used, because the sines and cosines of the multiples of an arc are more easily found than the powers of the sine and cosine.

Ex. 2. Let the differential be $dx \cos^2 x \sin^3 x$. In the first place, we have (Algebra, art. 260),

$\cos^2 x \sin^3 x = \frac{1}{16}(-\sin 5x + \sin 3x + 2\sin x).$

Hence, multiplying by dx, and integrating,

$\int dx \cos^2 x \sin^3 x = \frac{1}{80}\cos 5x - \frac{1}{48}\cos 3x - \frac{1}{8}\cos x + C.$

150. Method III.—It has been found (Algebra, art. 270), that e being the base of Napier's logarithms,

$$\cos x = \frac{e^{x\sqrt{-1}} + e^{-x\sqrt{-1}}}{2};$$

$$\sin x = \frac{e^{x\sqrt{-1}} - e^{x\sqrt{-1}}}{2\sqrt{-1}}.$$

These exponential expressions for the sine and cosine enable us to transform differentials containing circular functions into others involving exponential and logarithmic functions, and to integrate by the methods explained (art. 140–145).

151. Method IV.—We may reduce the integration of such a differential as $\sin^m x \cos^n x\,dx$, to that of another in which the indices of the sine or cosine are smaller numbers, by the formula $\int u\,dv = uv - \int v\,du$. For, making $u = \sin^{m-1} x$ and $dv = dx \sin x \cos^n x$, we find $v = -\frac{\cos^{n+1} x}{n+1}$, and

$$\int dx \sin^m x \cos^n x = -\frac{\sin^{m-1}}{n+1}x\cos^{n+1} x + \frac{m-1}{n+1}\int dx \cos^{n+2} x \sin^{m-2} x.$$

From this expression, by putting for $\cos^{n+2} x$, its value $\cos^n x\,(1-\sin^2 x)$, and transposing, we find

(α)

$$\int dx \sin^m x \cos^n x = -\frac{\sin^{m-1} x \cos^{n+1} x}{m+n} + \frac{m-1}{m+n}\int dx \sin^{m-2} x \cos^n x.$$

By resolving the proposed differential into the two factors $dx \cos x \sin^m x$ and $\cos^{n-1} x$, and proceeding in the same way, we find

(β)

$$\int dx \sin^m x \cos^n x = \frac{\sin^{m+1} x \cos^{n-1} x}{m+n} + \frac{n-1}{m+n}\int dx \sin^m x \cos^{n-2} x.$$

One of these formulæ serves to depress the exponent of the sine, and the other that of the cosine, and by their joint application the differential may be found when m and n are two positive integer numbers. For example,

$\int dx \sin^3 x \cos^2 x = -\frac{1}{5}\sin^2 x \cos^3 x + \frac{2}{5}\int dx \sin x \cos^2 x,$

$\int dx \sin x \cos^2 x = \frac{1}{3}\sin^2 x \cos x + \frac{1}{3}\int dx \sin x;$

this last term $= -\frac{1}{3}\cos x + C$, after collecting the terms, we have $\int dx \sin^3 x \cos^2 x =$

$\cos x\,(-\frac{1}{5}\sin^2 x \cos^2 x + \frac{2}{15}\sin^2 x - \frac{2}{45}) + C.$

152. When m and n are negative, these formulæ require some modification. The first, by changing n into $-n$, gives

(γ)

$$\int \frac{dx \sin^m x}{\cos^n x} = -\frac{\sin^{m-1} x}{(m-n)\cos^{n-1} x} + \frac{m-1}{m-n}\int \frac{dx \sin^{m-2} x}{\cos^n x}.$$

This makes the integral sought depend on that of $\frac{dx \sin x}{\cos^n x}$ or $\frac{dx}{\cos^n x}$, according as m is odd or even. By making $\cos x = z$, the first of these becomes $-\frac{dz}{z^n}$, of which the integral is obvious. The integral of the other will be shown presently in art. 153.

The second of the two general formulæ, by making n negative, and bringing the integral in the second side of the equation to stand alone, and lastly, changing n into $n-2$, gives

(δ)

$$\int \frac{dx \sin^m x}{\cos^n x} = \frac{\sin^{m+1} x}{(n-1)\cos^{n-1} x} - \frac{m-n+2}{n-1}\int \frac{dx \sin^m x}{\cos^{n-2} x}.$$

By this the integral sought is reduced to that of $dx \sin^m x$, or to $\frac{dx \sin^m x}{\cos x}$, according as n is even or odd. The first is found by formula (α) (art. 151), the other is presently to be noticed.

153. If we make m or $n = 0$, we have

$$\int dx \sin^m x = \frac{-\cos x \sin^{m-1} x}{m} + \frac{m-1}{m}\int dx \sin^{m-2} x,$$

$$\int dx \cos^n x = \frac{\sin x \cos^{n-1} x}{n} + \frac{n-1}{n}\int dx \cos^{n-2} x,$$

$$\int \frac{dx}{\sin^m x} = \frac{-\cos x}{(m-1)\sin^{m-1} x} + \frac{m-2}{m-1}\int \frac{dx}{\sin^{m-2} x}$$

$$\int \frac{dx}{\cos^n x} = \frac{\sin x}{(n-1)\cos^{n-1} x} + \frac{n-2}{n-1}\int \frac{dx}{\cos^{n-2} x}.$$

154. When the exponents of the sine and cosine are both negative, we multiply the numerator by $\cos^2 x + \sin^2 x = 1$, and have

$$\int\frac{dx}{\sin^m x\cos^n x}=\int\frac{dx}{\sin^{m-2}x\cos^n x}+\int\frac{dx}{\sin^m x\cos^{n-2}x},$$
fractions with $\sin x$ or $\cos x$ in the denominator.

If $m=n$, then because $\sin x\cos x=\frac{1}{2}\sin 2x$, by making $2x=z$, the fraction takes the form of the third of the preceding formulæ.

155. We shall conclude this branch of the subject by integrating four of the more elementary circular functions.

1. To integrate $\frac{dx}{\sin x}$. We observe that $\sin x=2\sin\frac{1}{2}x\cos\frac{1}{2}x$, therefore,
$$\frac{dx}{\sin x}=\frac{dx}{2\sin\frac{1}{2}x\cos\frac{1}{2}x}=\frac{1}{2}\frac{dx\sec^2\frac{1}{2}x}{\tan\frac{1}{2}x}=\frac{d.\tan\frac{1}{2}x}{\tan\frac{1}{2}x},$$
$$\text{and }\int\frac{dx}{\sin x}=\text{l. }(\tan\tfrac{1}{2}x)+\text{C}.$$

2. To integrate $\frac{dx}{\cos x}$. Putting $\frac{1}{2}\pi$ to denote an arc of $90°$, and $x=\frac{1}{2}\pi-z$, we have $dx=-dz$, $\cos x=\sin z$, and
$$\int\frac{dx}{\cos x}=\int\frac{-dz}{\sin z}=-\text{l.}\tan\tfrac{1}{2}z=\text{l.}\frac{1}{\tan\frac{1}{2}z}+\text{C}.$$
$$\text{Now }\frac{1}{\tan\frac{1}{2}z}=\frac{1}{\tan(\frac{1}{4}\pi-\frac{1}{2}x)}=\tan(\tfrac{1}{4}\pi+\tfrac{1}{2}x).$$
$$\text{Therefore }\int\frac{dx}{\cos x}=\text{l. }\tan(\tfrac{1}{4}\pi+\tfrac{1}{2}x)+\text{C}.$$
This and the preceding integral may be otherwise expressed thus,
$$\int\frac{dx}{\sin x}=\tfrac{1}{2}\text{l.}\frac{1-\cos x}{1+\cos x}+\text{C}.$$
$$\int\frac{dx}{\cos x}=\tfrac{1}{2}\text{l.}\frac{1+\sin x}{1-\sin x}+\text{C}.$$
$$3.\ \int\frac{dx}{\tan x}=\int\frac{dx\cos x}{\sin x}=\text{l. }(\sin x)+\text{C}.$$
$$4.\ \int dx\tan x=\int\frac{dx\sin x}{\cos x}=\text{l.}\frac{1}{\cos x}+\text{C}.$$

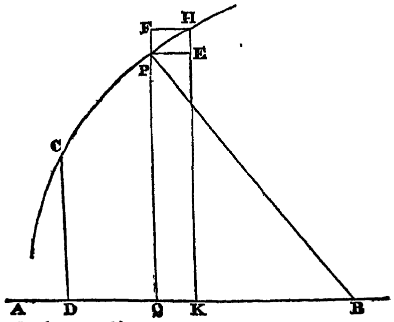
Applications of the Integral Calculus.

Before we proceed farther in the explanation of the theory of the calculus, we shall apply its principles to some of the more important problems in Geometry.

Quadrature of Curves.

156. Let $\text{AQ}=x$, $\text{PQ}=y$, be the co-ordinates of a curve, of which AB is the axis; and let the area CDQP, comprehended between CD, an ordinate given in position, and PQ any other ordinate, be denoted by s. We

Fig. 21.



have found (art. 69) that $ds=ydx$; therefore, in any curve whatever,
$$\text{area } s=\int ydx$$

Ex. 1. Let the curve be a parabola, of which p is the parameter. By the nature of the curve, $y^2=px$, and $y=p^{\frac{1}{2}}x^{\frac{1}{2}}$, and $ydx=p^{\frac{1}{2}}x^{\frac{1}{2}}dx$; therefore, taking the integral by art. 104,
$$s=\int ydx=\tfrac{2}{3}p^{\frac{1}{2}}x^{\frac{3}{2}}+c=\tfrac{2}{3}yx+\text{C}.........(1)$$
Let $\text{AD}=a$, $\text{CD}=b$; when $s=0$, then $x=a$, $y=b$. These values being substituted in the above general expression for the area, it becomes
$$0=\tfrac{2}{3}ab+\text{C}.$$
If we now subtract the sides of equation (2) from the corresponding sides of (1), the indeterminate constant C will disappear, and we shall have
$$s=\tfrac{2}{3}(xy-ab).$$
This is a convenient way of eliminating the indeterminate constant. If A, the origin of the abscissa x, be the vertex of the parabola, and if the area s be supposed to begin at the vertex, then $a=0$, $b=0$; and the area comprehended between the axis, an ordinate, and the curve, is $\frac{2}{3}xy$, that is, $\frac{2}{3}$ of the circumscribing parallelogram.

Ex. 2. Let the curve be a circle Apa (see fig. 7, art. 66), of which Aa is a diameter. Suppose the origin of co-ordinates to be at O, the centre; let Ob be the radius perpendicular to OA; put $\text{OQ}=x$, $p\text{Q}=y$, OA the radius $=a$, the space $\text{OQ}pb=s$; by the nature of the circle $x^2+y^2=a^2$, and $y=\sqrt{a^2-x^2}$; hence
$$s=\int ydx=\int dx\sqrt{a^2-x^2}.$$
This integral cannot be expressed in finite algebraic terms; therefore recourse must be had to an infinite series. By the binomial theorem, $\sqrt{a^2-x^2}=(a^2-x^2)^{\frac{1}{2}}=$
$$a-\frac{1\,.\,x^2}{2\,.\,a}-\frac{1\,.\,1\,.\,x^4}{2\,.\,4\,a^3}-\frac{1\,.\,1\,.\,3\,.\,x^6}{2\,.\,4\,.\,6\,a^5}-\text{\&c.}$$
Each term of this series being multiplied by dx, and the integral taken, we have
$$s=ax-\tfrac{1}{2}\cdot\frac{x^3}{3a}-\frac{1.1}{2.4}\cdot\frac{x^5}{5a^3}-\frac{1.1.3}{2.4.6}\cdot\frac{x^7}{7a^5}-\text{\&c.}+\text{C}.$$
To determine C, we consider that when $x=0$, then $s=0$, these values make both sides of the equation $=0$; therefore $\text{C}=0$; when $x=a$, then $s=\frac{1}{4}$ of the area of the circle; therefore the area of a circle whose radius $=a$ is
$$4a^2\left(\frac{1}{1}-\frac{1}{2}\cdot\frac{1}{3}-\frac{1.1}{2.4}\cdot\frac{1}{5}-\frac{1.1.3}{2.4.6}\cdot\frac{1}{7}-\text{\&c.}\right).$$
This series converges slowly, so that a considerable number of terms would be required to give its value near the truth. If we make $x=\cos$ arc $60°$, then, drawing the radius Op, the area OQpb will manifestly be made up of the sector POb, which is $\frac{1}{12}$ of the area of the circle, and the triangle OQp, which is $\frac{1}{2}\text{OQ}\,.\,p\text{Q}=\frac{\sqrt{3}}{8}a^2$.

Putting $\frac{a}{2}$ for x in the series, it will now converge much faster, and the sum of seven of its terms will be $\cdot4783057a^2$, from which subtracting $\frac{\sqrt{3}}{8}a^2=\cdot2165063a^2$, there remains $\cdot2617994a^2$ for $\frac{1}{12}$ of the area, and $3\cdot1415928a^2$ for the whole area of the circle. We have found this number by a less laborious calculation, in ALGEBRA, 273. We may make A, one end of the diameter (fig. 7, art. 66), the origin of the co-ordinates, so that $\text{AQ}=x$, $pq=y$, segment $\text{A}p\text{Q}=s$ · then, because $y=\sqrt{2ax-x^2}$, the area
$$s=\int dx\sqrt{2ax-x^2}=\int dx\sqrt{2ax}\left(1-\frac{x}{2a}\right)^{\frac{1}{2}}.$$
The integral of this expression will be had by convert-

ing $\left(1-\frac{x}{2a}\right)^{\frac{1}{2}}$ into a series, then multiplying the terms separately by $dx\sqrt{2ax}$, and integrating.

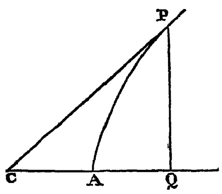
Ex. 3. To find the area of the elliptic segment APQ (fig. 7, art. 66). Let OA, the semitransverse, $=a$, OB, the semiconjugate, $=b$, AQ$=x$, PQ$=y$, the area APQ$=s$. By the nature of the ellipse, $y=\frac{b}{a}\sqrt{2ax-x^2}$; therefore the elliptic segment

$$s=\int ydx=\frac{b}{a}\int dx\sqrt{2ax-x^2}.$$

Let AP*a* be a semicircle on the same axis, and let s' denote the segment cut off by the ordinate *p*PQ, which is common to both curves. We found in last example that $s'=\int dx\sqrt{2ax-x^2}$; therefore $s=\frac{b}{a}s'$. Thus it appears that the area of APQ, any segment of an ellipse, has to the area of A*p*Q the corresponding segment of the circumscribing circle, the constant ratio of the lesser axis to the greater. Neither of the integrals require a constant, because both vanish when $x=0$.

Ex. 4. To find the area of the hyperbolic sector PCA, C being the centre of the hyperbola, and CA the semitransverse axis.

Fig. 22.



Draw the ordinate PQ; let the semitransverse axis CA $=a$, the semiconjugate axis $=b$, CQ $=x$, PQ $=y$, the sector PAC $=s$.
Because $s=$ triangle CPQ — space APQ $=\frac{1}{2}xy-\int ydx$; therefore $ds=\frac{1}{2}xdy+\frac{1}{2}ydx-ydx=\frac{1}{2}(xdy-ydx)$.

Now, by the nature of the curve, $y=\frac{b}{a}\sqrt{x^2-a^2}$, therefore $dy=\frac{b}{a}\frac{xdx}{\sqrt{x^2-a^2}}$, and

$$ds=\frac{b}{2a}\left\{\frac{x^2dx}{\sqrt{x^2-a^2}}-dx\sqrt{x^2-a^2}\right\}=\frac{1}{2}ab\frac{dx}{\sqrt{x^2-a^2}}.$$

Now, by art. 125, $\int\frac{dx}{\sqrt{x^2-a^2}}=\text{l.}\,(x+\sqrt{x^2-a^2})+\text{C}.$

$$\text{Therefore } s=\frac{ab}{2}\,\text{l.}\,(x+\sqrt{x^2-a^2})+\text{C}.$$

Here C denotes an indefinite constant: To determine its value, we consider that when $x=a$, then $s=0$; therefore in this particular case,

$$0=\frac{ab}{2}\,\text{l.}\,a+\text{C}.$$

Hence, by subtracting equals from equals, and observing that the difference of two logarithms is the logarithm of their quotient, we eliminate C, and have

$$s=\frac{ab}{2}\,\text{l.}\,\frac{x+\sqrt{x^2-a^2}}{a}.$$

Because $\sqrt{x^2-a^2}=\frac{ay}{b}$, therefore also

$$s=\frac{ab}{2}\,\text{l.}\,\left\{\frac{x}{a}+\frac{y}{b}\right\}.$$

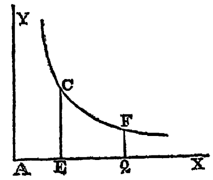
Ex. 5. To find the area of s, the hyperbolic space APQ, we have $s=$ triangle CPQ — sector CAP, or

$$s=\frac{1}{2}xy-\frac{ab}{2}\,\text{l.}\,\left\{\frac{x}{a}+\frac{y}{b}\right\}.$$

Ex. 6. Let the curve be an equilateral hyperbola, of which AX, AY are the asymptotes: To find s, the area included by the hyperbolic arc CF, the straight lines CE, FQ, which are parallel to one asymptote, and EQ, the segment of the other asymptote between them; suppose CE one of the parallels to be given in position. Put AE $=a$, EC $=b$, AQ $=x$, EQ$=y$. By the nature of the curve, $xy=ab$; hence $y=\frac{ab}{x}$, and

$$s=\int ydx=ab\int\frac{dx}{x}=ab\,\text{l.}\,x+\text{C}.$$

Fig. 23.



Now, when $x=a$, then $s=0$; in this case $0=ab\,\text{l.}\,a+\text{C}$, or $\text{C}=-ab\,\text{l.}\,a$; hence, substituting for C its value, and putting $\text{l.}\,\frac{x}{a}$ for $\text{l.}\,x-\text{l.}\,a$, we have

$$s=ab\,\text{l.}\,\frac{x}{a}.$$

From this formula we find $\text{l.}\,\frac{x}{a}=\frac{s}{ab}$. Thus it appears that Napier's logarithm of any number $\frac{x}{a}$ may be expressed by a hyperbolic area; hence it has happened that the logarithms of his system have been called *hyperbolic*.

If M be the *modulus* of any system, the log of $\frac{x}{a}$ in that system will be M $\text{l.}\,\frac{x}{a}$; therefore, in any system of which the modulus is M, we have

$$\log.\,\frac{x}{a}=\frac{\text{M}}{ab}s.$$

Thus we see that logarithms of any system may be expressed geometrically by hyperbolic areas, and therefore that the name *hyperbolic logarithms* cannot with propriety be given to one kind of logarithms rather than to another.

Ex. 7. Let the curve be the cycloid (fig. 9, art. 66), of which AC is the axis, and AH a perpendicular to the axis at the vertex A. From any point in the curve draw PG perpendicular to AH: it is proposed to find s, the area of the external space contained by the straight lines AG, GP, and the cycloidal arc AP.

Let O be the centre of the generating circle; draw PDQ perpendicular to AC, meeting the circle in D, and join OD. Put $x=$ AG, $y=$ PG, $a=$ AO, $v=$ angle AOD; then (art. 66) PQ $=a(v+\sin v)$, AQ $=a(1-\cos v)$, therefore,
$x=a(v+\sin v)$, $y=a(1-\cos v)$, $dx=adv(1+\cos v)$,
$ds=a^2(1-\cos v)(1+\cos v)dv=a^2dv\sin^2 v$,
and integrating by 153,

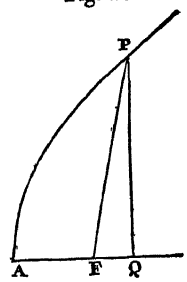
$$s=a^2\int dv\sin^2 v=\frac{a^2}{2}(v-\sin v\cos v)+\text{C}.$$

When $v=0$, then s ought to vanish; this requires that $\text{C}=0$. Putting now the arc AD for av, and DQ · OQ for $a^2\sin v\cos v$, we have
$s=\frac{1}{2}$ AO · arc AD — $\frac{1}{2}$ DQ · OQ $=$ circ. seg. ADQ.

Inverse Method.

Ex. 8. To find the area contained by AF, a line drawn from the focus of a parabola to the vertex, FP a line drawn to any point of the curve, and the intercepted arc AP.

Fig. 24.



Let a denote the parameter $=4$AF, $u=$ the angle AFP, $r=$ FP, $s=$ the parabolic sector APF. Draw PQ perpendicular to the axis AF. By the nature of the curve, PF $=$ AQ$+$AF. Now, supposing PFA to be an obtuse angle, FQ $=-r\cos v$, AQ $=\frac{1}{4}a-r\cos v$, AF $=\frac{1}{4}a$, therefore, $r=\frac{1}{2}a-r\cos v$, and $r(1+\cos v)=\frac{1}{2}a$; hence, since $1+\cos v=2\cos^2\frac{1}{2}v$, $r=\dfrac{a}{4}\dfrac{1}{\cos^2\frac{1}{2}v}$.

Now, by formula 3, article 70, $ds=\frac{1}{2}r^2dv$, therefore

$$ds=\frac{a^2}{16}\frac{\frac{1}{2}dv}{\cos^4\frac{1}{2}v}.$$

To integrate this differential, we consider that

$$\frac{\frac{1}{2}dv}{\cos^2\frac{1}{2}v}=\sec^2\tfrac{1}{2}v\frac{dv}{2}=d(\tan\tfrac{1}{2}v);$$

and that $\dfrac{1}{\cos^2\frac{1}{2}v}=\sec^2\frac{1}{2}v=1+\tan^2\frac{1}{2}v$;

therefore, multiplying these equations, we get

$$\frac{\frac{1}{2}dv}{\cos^4\frac{1}{2}v}=d(\tan\tfrac{1}{2}v)+\tan^2\tfrac{1}{2}v\,d(\tan\tfrac{1}{2}v);$$

and hence, integrating by the rule art. 104, we find

$$\int\frac{\frac{1}{2}dv}{\cos^4\frac{1}{2}v}=\tan\tfrac{1}{2}v+\tfrac{1}{3}\tan^3\tfrac{1}{2}v+\text{C}.$$

Observing now that when $v=0$, then $s=0$; therefore C $=0$, and we have

$$s=\frac{a^2}{16}(\tan\tfrac{1}{2}v+\tfrac{1}{3}\tan^3\tfrac{1}{2}v).$$

This integral might have been found by the formula of art. 153; not so easily, however. The formula here found is wanted in the astronomy of comets.

157. Since the area of any plane curve is expressed by an integral $\int ydx$, in which y the ordinate is some function of x the absciss, so, on the other hand, any integral may be represented geometrically by the area of a curve. The geometrical representation of an integral shows distinctly wherein it differs from a common analytic function, such as $a+bx^n$, or ax, or $\sin x$, &c. These last have determinate values corresponding to any given value of x, and each is independent of its preceding and following values; but the magnitude of the space represented by an integral $\int ydx$ is the increment that a certain area receives while the variable x passes from one state of magnitude to another. Thus the absolute magnitude of the space CDQP (fig. 11), which represents an integral $\int ydx$, and which, when the curve is a parabola, is expressed by $\frac{2}{3}xy+$C, cannot be known before C is determined, or else eliminated from the expression.

Whatever be the nature of the curve, the integral $\int ydx=$ space CPQD is correctly indicated, so as to admit of being computed, when we say that it is generated while the variable x increases from any value $=$ AD, to another value $=$ AQ, the lines AD, AQ being supposed given in magnitude, and the relation between x and y known. The same thing is briefly indicated by this notation:

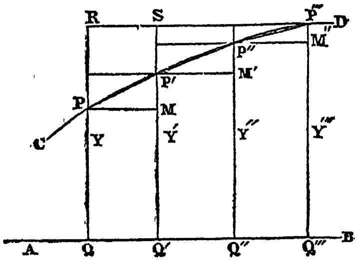
$$\text{area CPQD}=\int_a^x ydx,$$

in which a and x denote the lines AD and AQ.

From what has been shown it appears that an integral is an indeterminate quantity, the result of a change in the value of its variable; and that to know its absolute value we must know the values of the variable at its commencement and completion.

158. The analogy between a curvilineal area and an integral indicates a general method of finding its numerical value to any degree of nearness. Supposing y to be any function of x, let it be proposed to find the integral $\int ydx$ between $x=a$ and $x=b$.

Fig. 25.



Let CPD be a curve, of which the co-ordinates are x and y. In the axis AB, take AQ $=a$, the least value of x, and AQ‴ $=b$, its greatest value, and draw the ordinates PQ, P‴Q‴. The area PQQ‴P‴ will be the geometrical expression of the integral between the proposed limits; and by whatever means that area can be found, the same will apply to the determination of the integral.

Divide QQ‴ into any number of equal parts at the points Q′, Q″, &c. and draw the ordinates P′Q′, P″Q″, &c. These will divide the whole figure into the spaces PP′Q′Q, P′P″Q″Q′, &c. Let a series of rectangles PQ′, P′Q″, P″Q‴ be formed, each having the least of two adjoining ordinates for a side: these will fall within the curve, supposing it to be entirely concave or convex towards the axis. Let another series P′Q, P″Q′, P‴Q″ be constructed, each having the longest of two adjoining ordinates for a side: the aggregate of these will exceed the area of the curve. The length of the base of each rectangle will be known, and, from the nature of the curve, its height will also be known; hence the areas of all the rectangles may be found. The sum of the areas of the inscribed rectangles will be less than the integral, and the sum of the areas of the circumscribing rectangles will be greater. The difference between these sums is the rectangle PMSR, which, by supposing its base PM $=$ QQ′ to be sufficiently small, may be less than any assignable space. Thus an approximate value of the integral may be found, which shall differ from the truth by as small a quantity as we please.

Draw the chords PP′, P′P″, P″P‴, thus forming a series of trapeziums, which will differ from the curvilineal area by less than the sum of either the inscribed or circumscribing parallelograms, and will be a mean between them. This will be a nearer approximation than either sum to the integral.

As an example of the application of this method, let it be proposed to approximate to the integral $\int_0^1\dfrac{dx}{1+x^2}$, that is, to the arc whose tangent is x, between the values of $x=0$ and $x=1$, which arc is $\dfrac{1}{4}$ of a semicircle, the radius

being supposed $= 1$. In this case the equation of the curve is $y = \frac{1}{1+x^2}$. Let us suppose the base QQ‴ to be divided into ten equal parts; then, making $x = 0$, $x = \cdot 1$, $x = \cdot 2$, &c. to $x = 1$, we obtain eleven equidistant ordinates or values of y as follows:

The 1*st*,	1.00000	The 7*th*,	·73529
2*d*,	·99010	8*th*,	·67114
3*d*,	·96154	9*th*,	·60975
4*th*,	·91743	10*th*,	·55249
5*th*,	·86207	11*th*,	·50000
6*th*,	·80000		

By the elements of geometry, the area of the rectilineal figure formed by the trapeziums is found by adding together all the ordinates except the first and last, and half the sum of the first and last, and multiplying the result by the common breadth of the trapeziums, which is ·1. This gives ·784981 for the area or value of the integral $\int_0^1 \frac{dx}{1+x^2}$. The true value expressed by a series is $1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} +$ &c. which converges too slowly to be of any practical use: by other methods the more correct value of the integral is ·7854 nearly.

159. Supposing the ordinates PQ, P′Q′, &c. to go on continually increasing, the inscribed rectangles will be constructed on the 1st, 2d, 3d, &c. ordinates, and the circumscribing rectangles on the 2d, 4th, 6th, &c.

Observing now that the ordinates are the values of y corresponding to AQ, AQ′, &c. values of x, which differ by the common interval QQ′, we have manifestly the following rule for approximating to an integral $\int ydx$ between the limits of $x = \mathrm{AQ} = a$ and $x = \mathrm{AQ}''' = b$. Divide the interval $\mathrm{QQ}''' = b - a$ into n equal parts, each equal to h.

Find Y, Y′, Y″, ... $\mathrm{Y}^{(n)}$ the particular values of Y corresponding to $x = a$, $x = a + h$, $x = a + 2h$ .... $x = a + nh = b$.

Then, supposing the ordinates to go on increasing,

$$\int_a^b ydx > h\,(\mathrm{Y} + \mathrm{Y}' + \mathrm{Y}'' \ldots . + \mathrm{Y}^{(n-1)});$$

$$\int_a^b ydx < h\,(\mathrm{Y}' + \mathrm{Y}'' + \mathrm{Y}''' \ldots . + \mathrm{Y}^{(n)}).$$

The difference of these is $h(\mathrm{Y}^{(n)} - \mathrm{Y})$, which, by taking h sufficiently small, may be as small as we please. We may reason in the same way when the ordinates form a decreasing series. If they first increase and then decrease, the interval $b - a$ may be divided into two or more portions, such that y increases or decreases continually from one end of each to the other.

Whatever be the values of y, provided they be always finite from $x = a$ to $x = b$, putting for them Y, Y′, Y″ .. $\mathrm{Y}^{(n)}$, we have

$$\int_a^b ydx \,. = \mathrm{Y}h + \mathrm{Y}'h + \mathrm{Y}''h \ldots . + \mathrm{Y}^{n-1}\,h.$$

Leibnitz and his followers considered the integral $\int ydx$ as the sum of the infinitely little elements Yh, Y′h, &c. Hence the origin of the terms integral, to integrate, integration, &c. When h is infinitely little, and represented by dx, the differential of x, then ydx is the differential of the integral.

Rectification of Curves.

160. We have found (art. 72) that z being any arc of a curve referred to an axis by rectangular co-ordinates x, y, the differential of the arc, viz. $dz, = \sqrt{dx^2 + dy^2}$. We are now to apply the calculus to particular curves.

Ex. 1. Let the curve be a parabola (fig. 16) of which the parameter $= 2a$, the absciss $\mathrm{AQ} = x$, the ordinate $\mathrm{PQ} = y$. The equation of the curve, $2ax = y^2$, gives

$$adx = ydy \text{ and } dz = \sqrt{dx^2 + dy^2} = \frac{1}{a}dy\sqrt{a^2 + y^2}.$$

If in formula B, art. 135, we make $m = 1$, $n = 2$, $p = \frac{1}{2}$, $b = 1$, and put y instead of x, and a^2 instead of a, we have

$$\int dy\sqrt{a^2 + y^2} = \tfrac{1}{2}\,y\sqrt{a^2 + y^2} + \tfrac{1}{2}\,a^2\int\frac{dy}{\sqrt{a^2 + y^2}}.$$

The integral in the second side of this equation is, by the formula of art. 130, $\mathrm{l.}\,(y + \sqrt{a^2 + y^2}) + \mathrm{C}$; therefore $z = \frac{y}{2a}\sqrt{a^2 + y^2} + \frac{a}{2}\,\mathrm{l.}\,(y + \sqrt{a^2 + y^2}) + \mathrm{C}$.

If we suppose z to begin at the vertex, then, when $z = 0, y = 0$; therefore $\mathrm{C} = -\frac{a}{2}\,\mathrm{l.}\,a$, and

$$z = \frac{y}{2a}\sqrt{a^2 + y^2} + \frac{a}{2}\,\mathrm{l.}\,\frac{y + \sqrt{a^2 + y^2}}{a}.$$

Ex. 2. Let the curve be the second cubic parabola of which the equation is $y^3 = ax^2$. In this case the general formula gives

$$dz = dy\sqrt{1 + \frac{9y}{4a}} \text{ and } z = \tfrac{8}{27}\sqrt{\left(1 + \frac{9y}{4a}\right)^3} + \mathrm{C}.$$

This curve is perfectly rectifiable. Indeed it is the evolute of the parabola (art. 81, ex. 1).

Ex. 3. Let the curve be a circle (fig. 7), of which the radius $\mathrm{OA} = a$. Reckoning the co-ordinates from the centre, let $\mathrm{OQ} = x$, $p\mathrm{Q} = y$, $b\mathrm{P} = z$. The equation of the curve is $x^2 + y^2 = a^2$; hence $y = \sqrt{a^2 - x^2}$, $dy = -\frac{xdx}{\sqrt{a^2 - x^2}}$ and $dz = \frac{adx}{\sqrt{a^2 - x^2}}$. This integral cannot be otherwise expressed than by an infinite series. We have already found it (art. 139, ex. 4) on the supposition that the radius $= 1$; when the radius $= a$, we have only to put $\frac{x}{a}$ instead of x, thence we get

$$z = x + \frac{1}{2}\cdot\frac{x^3}{3a^2} + \frac{1.3}{2.4}\cdot\frac{x^5}{5a^4} + \frac{1.3.5}{2.4.6}\frac{x^7}{7a^6} + \&\text{c}.$$

There is no constant wanted; because, from the nature of the case, z and x begin together.

From this example, also from ex. 2, art. 156, and ex. 2, art. 139, it appears that the quadrature, also the rectification of the circle, is equivalent to the determination of any one of these integrals, $\int dx\sqrt{1 - x^2}$, $\int\frac{dx}{\sqrt{1 - x^2}}$, $\int\frac{dx}{1 + x^2}$, which is a problem in pure analysis, and which does not seem to admit of a solution in finite terms. The solution of that celebrated geometrical problem is therefore hopeless.

Ex. 4. Let the curve be an ellipse (fig. 7), of which the semitransverse axis $\mathrm{OA} = 1$, the semiconjugate $\mathrm{OB} = b$, the eccentricity, which is $\sqrt{1 - b^2}, = e$. Let O the centre be the origin of the co-ordinates $\mathrm{OQ} = x$, $\mathrm{PQ} = y$; and, reckoning the arc from the extremity of the lesser axis, let $\mathrm{BP} = z$. By the nature of the curve, $y = b\sqrt{1 - x^2}$, therefore $dy = \frac{-bxdx}{\sqrt{1 - x^2}}$, and

$$dz = \sqrt{dx^2 + dy^2} = \frac{dx\sqrt{1 - (1 - b^2)x^2}}{\sqrt{1 - x^2}} = \frac{dx\sqrt{1 - e^2x^2}}{\sqrt{1 - x^2}}.$$

The integral of this differential is of such a nature as not to admit of being expressed either by arcs of a circle or logarithms. Therefore it can only be expressed by infinite series.

By the binominal theorem $\sqrt{1-e^2x^2}=$

$$1-\tfrac{1}{2}e^2x^2-\frac{1.1}{2.4}e^4x^4-\frac{1.1.3}{2.4.6}e^6x^6-\frac{1.1.3.5}{2.4.6.8}e^8x^8-\text{\&c.}$$

The terms of this series must now be multiplied each by $\frac{dx}{\sqrt{1-x^2}}$, and the integrals found, and their sum will express the length of the arc z.

The integrals, leaving out the numeral co-efficients, will all have the form $\int\frac{x^{2n}dx}{\sqrt{1-x^2}}$; therefore they will be found by the second formula of article 137. Thus, putting φ for the arc whose sine is x, we have

$$\int\frac{dx}{\sqrt{1-x^2}}=\varphi,$$

$$\int\frac{x^2dx}{\sqrt{1-x^2}}=-\tfrac{1}{2}x\sqrt{1-x^2}+\tfrac{1}{2}\varphi,$$

$$\int\frac{x^4dx}{\sqrt{1-x^2}}=-\left(\tfrac{1}{4}x^3+\frac{1.3}{2.4}x\right)\sqrt{1-x^2}+\frac{1.3}{2.4}\varphi,$$

&c.

These integrals being multiplied by their respective coefficients, we have the elliptic arc $z=$

$$\varphi\left(1-\frac{1.1}{2.2}e^2-\frac{1.1.3}{2.2.4.4}e^4-\frac{1.1.3.3.5}{2.2.4.4.6.6}e^6-\text{\&c.}\right)$$
$$+\tfrac{1}{2}e^2(\tfrac{1}{2}x\sqrt{1-x^2})$$
$$+\frac{1.1}{2.4}e^4\left(\tfrac{1}{4}x^3+\frac{1.3}{2.4}x\right)\sqrt{1-x^2}$$
$$+\frac{1.1.3}{2.4.6}e^6\left(\tfrac{1}{6}x^5+\frac{1.3}{4.6}x^3+\frac{1.3.5}{2.4.6}x\right)\sqrt{1-x^2}$$
$$+\text{\&c.}$$

Here no constant is wanted, because the functions on both sides of $=$ vanish when $x=0$, as they should.

If we make $x=1$, then all the terms multiplied by $\sqrt{1-x^2}$ vanish; and as in this case $\varphi=$ a quadrant $=\frac{1}{2}\pi$, we get the elliptic quadrant AB $=$

$$\tfrac{1}{2}\pi\left(1-\frac{1.1}{2.2}e^2-\frac{1.1.3}{2.2.4.4}e^4-\frac{1.1.3.3.5}{2.2.4.4.6.6}e^6-\text{\&c.}\right)$$

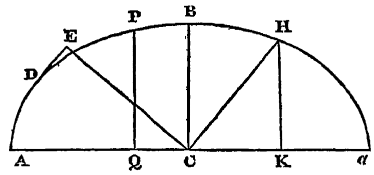
This expression converges pretty fast when e is small, but when e is nearly $=1$, it is hardly of any use. To have a complete solution, we ought to have another series suited to the case of $e=1$ nearly. Our limits, however, do not admit of our entering on its investigation here. The integration of the differential $\frac{dx\sqrt{1-e^2x^2}}{\sqrt{1-x^2}}$, which, putting φ for the arc whose sine $=x$, may be also expressed thus, $d\varphi\sqrt{1-e^2\sin^2\varphi}$, has greatly engaged the attention of mathematicians. On this subject consult the works quoted in the conclusion of our History of Fluxions, page 640.

The length of a hyperbolic arc may be found exactly in the same way as that of the ellipse from its equation $y=b\sqrt{x^2-1}$.

161. We shall here explain the remarkable property of the ellipse, first discovered by Fagnani, as has been mentioned, page 640, and which has proved the fertile germ of some of the finest discoveries in the modern analysis.

In the ellipse ABa, let DE be a tangent at any point D in the curve, draw CE from the centre perpendicular to the tangent, and parallel to it draw the semidiameter CH, which will be the conjugate to that drawn from C through D; and draw HK perpendicular to the axis. Let CA $=1$, CB $=b$, $\sqrt{1-b^2}$, the eccentricity, $=e$. Make the

Fig. 26.



perpendicular CE $=p$, the tangent DE $=t$, the angle ACE $=$ CHK $=\varphi$, and the arc AD $=z'$. By the nature of the ellipse, $CA^2\cdot HK^2=CB^2(CA^2-CK^2)$, that is, because HK $=$ CH cos φ, and CK $=$ CH sin φ, $CH^2\cos^2\varphi=b^2(1-CH^2\sin^2\varphi)$, and hence $b^2=CH^2(\cos^2\varphi+b^2\sin^2\varphi)=CH^2(1-e^2\sin^2\varphi)$, and $CH=\frac{b}{\sqrt{1-e^2\sin^2\varphi}}$.

Now, by the nature of the ellipse, $CH=\frac{CA\cdot CB}{CE}=\frac{b}{p}$, therefore $p=\sqrt{1-e^2\sin^2\varphi}$. Now it has been shown (art. 75) that in every curve $d(z+t)=pd\varphi$, and therefore $z+t=\int pd\varphi$; hence, in the ellipse, $z'+t=\int d\varphi\sqrt{1-e^2\sin^2\varphi}$.

In the semi-axis CA take CQ $=$ CA $\cdot$ sin ECA $=$ sin φ, draw the ordinate QP, and put $z=$ elliptic arc BP. By what was shown in last article, $dz=d\varphi\sqrt{1-e^2\sin^2\varphi}$, and $z=\int d\varphi\sqrt{1-e^2\sin^2\varphi}$; thence it appears that the functions $z'+t$ and z have the same differential, therefore they can only differ by a constant, that is, $z'+t=z+C$. Now when $z=0$, then $\varphi=0$, and $z'=0$, also $t=0$; therefore the variables z, z', and t' begin together, and the constant $C=0$; thus we have $z'+t=z$ and $z-z'=t$. Hence we have this very remarkable property of an ellipse. At any point D in the curve draw a tangent DE, and from the centre C draw CE perpendicular to the tangent. In CA take CQ $=$ CA $\cdot$ sin ECA; draw the ordinate PQ. *The difference of the elliptic arcs* BP, AD (*that is,* BP $-$ AD), *is equal to the tangent* DE. *This is in substance Fagnani's theorem. Hence it follows that any arc of an ellipse being given, another may be found by a geometrical construction, such, that their difference shall be an assignable straight line.*

We have found (art. 75) that in all curves $t=\frac{-dp}{d\varphi}$. In the ellipse $p=\sqrt{1-e^2\sin^2\varphi}$ and $\frac{dp}{d\varphi}=\frac{-e^2\sin\varphi\cos\varphi}{\sqrt{1-e^2\sin^2\varphi}}$. Therefore, without any reference to the length of the tangent,

$$z-z'=\frac{e^2\sin\varphi\cos\varphi}{\sqrt{1-e^2\sin^2\varphi}}.$$

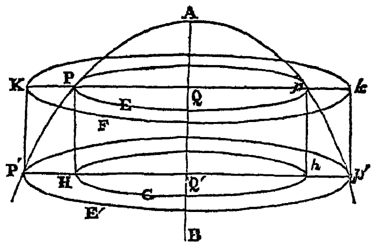
There are corresponding properties of the hyperbola, but our limits forbid our entering on them.

Cubature of Solids.

162. Let AB be the axis of any plane curve APP′, and PQ, P′Q′ ordinates perpendicular to the axis; draw PH perpendicular to the ordinate P′Q′, and P′K perpendicular to PQ. Conceive now the plane figure AP′Q′ to revolve about the axis AB; the curve AP will generate a solid AP′E′p', called a *solid of revolution;* and the rectangles

PQQ′H, P′Q′QK will generate cylinders whose bases are circles PEp, P′E′p', and common altitude QQ′.

Fig. 27.



Put AQ $= x$, AQ′ $= x'$, PQ $= y$, P′Q′ $= y'$; the solid generated by the space APQ $= s$, that generated by AP′Q′ $= s'$. Let $\pi = 3{\cdot}1416 =$ the area of a circle whose radius is 1. The content of the cylinder whose base is PEp will be $\pi(x'-x)y^2$, and that of the cylinder whose base is P′E′p' will be $\pi(x'-x)y'^2$.

The solid generated by the curvilineal space PQQ′P′ being greater than the cylinder whose base is PEp, but less than the cylinder whose base is P′E′p', we have

$$s'-s > \pi(x'-x)y^2, \text{ and } s'-s < \pi(x'-x)y'^2;$$

$$\text{therefore } \frac{s'-s}{x'-x} > \pi y^2, \text{ and } \frac{s'-s}{x'-x} < \pi y'^2.$$

Conceive now the circle P′E′p' to approach continually to the circle PEp; they will ultimately coincide and be equal; therefore πy^2 is the limit of $\frac{s'-s}{x'-x}$, and consequently $\frac{ds}{dx} = \pi y^2$, and

$$ds = \pi y^2 dx, \text{ and } s = \pi\textstyle\int y^2 dx.$$

By this formula the content of a solid of revolution generated by any given plane curve may be found.

163. Ex. 1. Let the solid be a paraboloid generated by the revolution of a parabola AP about its axis AQ. By the nature of the curve, $y^2 = ax$; therefore, in this case,

$$s = \pi\textstyle\int axdx = \frac{1}{2}\pi ax^2 + C = \frac{1}{2}\pi xy^2 + C.$$

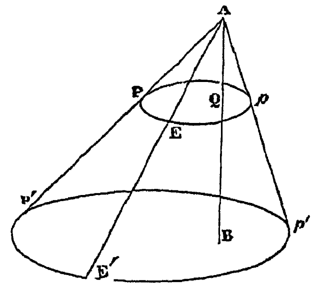
If the integral begin when $x = 0$, then also $s = 0$ and $C = 0$; now πxy^2 is the content of a cylinder having the same base as the paraboloid, therefore, *a paraboloid is half a cylinder of the same base and altitude.*

From this geometrical theorem we may find the content of the solid between two sections of a paraboloid by planes perpendicular to its axis, which is called a *frustum* of a paraboloid. Let A be the area of the base of the frustum, a the area of its top, h its height, x the segment of the axis between the vertex of the paraboloid and top of the frustum. The content of the whole paraboloid $= \frac{1}{2}(x+h)\text{A}$, and the content of the part cut off $= \frac{1}{2}xa$, therefore the content of the frustum $= \frac{1}{2}(x\text{A}+h\text{A}-xa)$. Now by the nature of the solid $\frac{x+h}{x} = \frac{\text{A}}{a}$, hence $x\text{A}-xa = ha$, therefore the content of the frustum is $\frac{1}{2}(\text{A}+a)h$. Hence it appears that a frustum of a paraboloid is equal to a cylinder of the same altitude, and whose base is a mean between the top and bottom of the frustum.

Ex. 2. Let the solid be a cone whose vertex is A, and base P′Ep', a plane figure of any kind.

Let AB be the altitude of the cone, and PEp a section parallel to the base, meeting AB in Q. Let $b =$ the area of the base P′Ep', $v =$ area of section PEp, $c =$ AB, $x =$ AQ, $s =$ content of solid A-PEp. In this case, $ds = vdx$, an expression the same as for a solid of revolution, and found in the same way. Now, sections of similar cones are proportional to the squares of their like

Fig. 28.

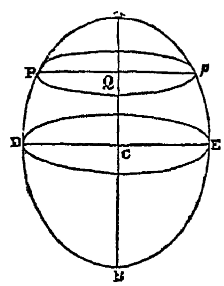


dimensions; therefore $c^2 : x^2 = b : v$, hence $v = \frac{bx^2}{c^2}$ and $ds = \frac{b}{c^2}x^2dx$, and by integration $s = \frac{bx^3}{3c^2} + C = \frac{vx}{3} + C$. If x and s begin together, then $C = 0$ and $s = \frac{1}{3}vx$. Thus it appears that *a cone of any kind is $\frac{1}{3}$ of its circumscribing cylinder.*

To find the content of a frustum of a cone, or space between the base and a plane parallel to its base; put A $=$ area of base, $a =$ area of top, $h =$ height of frustum, $x =$ height of cone cut off above the frustum. The content of the whole cone $= \frac{1}{3}(h+x)\text{A}$, and the content of the part cut off $= \frac{1}{3}xa$, therefore the content of the frustum $= \frac{1}{3}(h\text{A}+x\text{A}-xa) = \frac{1}{3}h\text{A} + \frac{1}{3}x(\text{A}-a)$. Now $\frac{\text{A}}{a} = \frac{(x+h)^2}{x^2}$, and $\frac{\sqrt{\text{A}}}{\sqrt{a}} = \frac{x+h}{x}$ hence $x = \frac{\sqrt{a}}{\sqrt{\text{A}}-\sqrt{a}}h$, and $x(\text{A}-a) = \sqrt{a}(\sqrt{\text{A}}+\sqrt{a})h = (\sqrt{\text{A}a}+a)h$. On the whole, the content of the frustum $= \frac{1}{3}(\text{A}+a+\sqrt{\text{A}a})h$.

Ex. 3. To find the content of a spheroid generated by the revolution of an ellipse about either of its axes.

Fig. 29.



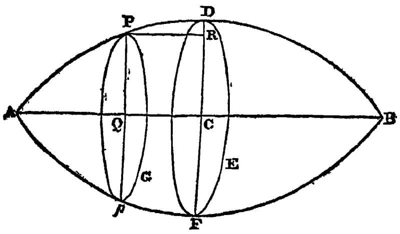
Let PQp be a section of the solid perpendicular to the fixed axis AB. Put AB $= a$, the revolving axis DE $= b$, also AQ $= x$, PQ $= y$. From the nature of the ellipse, $y^2 = \frac{b^2}{a^2}(ax-x^2)$, hence $s = \frac{\pi b^2}{a^2}\int(ax-x^2)dx = \frac{\pi b^2}{a^2}(\frac{1}{2}ax^2 - \frac{1}{3}x^3) + C$.

If we suppose $s = 0$ when $x = 0$, then $C = 0$. If we make $x = a$, then s, the whole spheroid, $= \frac{ab^2\pi}{6} = \frac{2}{3}a \times$ area of middle section. Hence it appears that *the whole solid is $\frac{2}{3}$ of its circumscribing cylinder.* This proposition was discovered by Archimedes.

If the axes a, b, be supposed equal, the solid is a sphere; hence it appears that the content of a sphere $= \frac{\pi}{6}a^3$, a being the diameter.

Ex. 4. Let the solid be a parabole spindle which is generated by the revolution of APB, an arc of a parabola, about ACB, an ordinate to its axis. From P any point in

Fig. 30.



the revolving curve, draw PQ perpendicular to the ordinate AB, and PR perpendicular to the axes of the parabola. Make DC $= p$, AC $= q$, CQ $=$ PR $= x$, PQ $=$ CR $= y$, the solid (between the sections DEF, PGp) $= s$. By the nature of the curve, $PR^2 : AC^2 = DR : DC$; that is, $x^2 : q^2 = p - y : p$; hence $p\,x^2 = pq^2 - q^2 y$, and $y^2 = \frac{p^2}{q^4}(q^4 - 2q^2x^2 + x^4)$, and

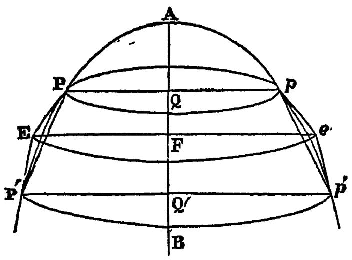
$$s = \frac{p^2\pi}{q^4}\int(q^4dx - 2q^2x^2dx + x^4dx)$$
$$= \frac{p^2\pi}{q^4}(q^4x - \tfrac{2}{3}q^2x^3 + \tfrac{1}{5}x^5) + \mathrm{C}.$$

If the integral begin when $x = 0$, then $\mathrm{C} = 0$. If we make $x = q$, we get $\frac{8}{15}p^2.q\pi$ for half the content of the solid generated by the curve ADB.

Surfaces of Solids.

164. Let AB be the axis of any plane curve APP′, and PQ, P′Q′ ordinates to the axis; draw PE, P′E tangents to the curve at P and P′, meeting in E; draw EF perpendicular to AB, and draw the chord PP′.

Fig. 31.



Suppose now the curve to revolve about its axis AB; the arc APP′ will generate a curve surface, to be found; the portion PP′ of the arc will generate an increment of that surface, which, by an axiom in geometry, will be less than the sum of the conical surfaces generated by the tangents PE, P′E, but greater than the conical surface generated by the chord PP′. Put AQ $= x$, AQ′ $= x'$, PQ $= y$, P′Q′ $= y'$, EF $= y''$, arc AP $= z$, arc AP′ $= z'$, surface generated by arc AP $= v$, surface generated by arc AP′ $= v'$.

By the elements of geometry, the surfaces generated by the tangents PE P′E will be

$$\pi(\mathrm{PQ} + \mathrm{EF})\,\mathrm{PE} = \pi(y + y'')\,\mathrm{PE},$$
$$\pi(\mathrm{P'Q'} + \mathrm{EF})\,\mathrm{P'E} = \pi(y' + y'')\,\mathrm{P'E},$$

and the surface generated by the chord PP′ will be

$$\pi(\mathrm{PQ} + \mathrm{P'Q'})\,\mathrm{PP'} = \pi(y + y')\,\mathrm{PP'}.$$

Therefore $v' - v < \pi\{(y + y'')\,\mathrm{PE} + (y' + y'')\,\mathrm{P'E}\}$,

$$v' - v > \pi(y + y')\text{ chord PP}',$$

and $$\frac{v' - v}{z' - z} < \pi\frac{(y + y'')\,\mathrm{PE} + (y' + y'')\,\mathrm{P'E}}{\text{arc P}'\mathrm{P}},$$

$$\frac{v' - v}{z' - z} > \pi(y + y')\frac{\text{chord P}'\mathrm{P}}{\text{arc P}'\mathrm{P}}.$$

Now, the point P being supposed to approach to P′, these quantities, one of which is greater than $\frac{v' - v}{z' - z}$, and the other less, become ultimately equal; for the lines y, y'', y' become equal, and $(y + y'')\,\mathrm{PE} + (y + y'')\,\mathrm{PE}$ becomes $(y' + y)(\mathrm{PE} + \mathrm{P'E})$, and the fractions $\frac{\mathrm{PE} + \mathrm{P'E}}{\text{arc P}'\mathrm{P}}$, $\frac{\text{chord PP}'}{\text{arc PP}'}$ are ultimately each $= 1$; therefore,

$$\text{limit}\,\frac{v' - v}{z' - z} = 2\pi y,\ \text{and}\ \frac{dv}{dz} = 2\pi y;$$

hence, $dv = 2\pi y dz = 2\pi y\sqrt{dx^2 + dy^2}$.

Now $2\pi y$ expresses the circumference of the section Pp; hence it appears that *the differential of the surface of revolution is equal to the differential of the arc of the generating curve multiplied by a section of the surface made by a plane perpendicular to the axis.*

165. Ex. 1. Let the solid be a sphere, of which the radius is a. Then, making AQ$=x$, PQ$=y$, the arc AP$=z$, the surface of the segment cut off by the plane P$p = v$; the equation of the curve being $y = \sqrt{2ax - x^2}$, we have

$$dy = \frac{adx - xdx}{\sqrt{2ax - x^2}},\ dz = \sqrt{dx^2 + dy^2} = \frac{adx}{\sqrt{2ax - x^2}} = \frac{adx}{y},$$

$dv = 2\pi y dz = 2a\pi dx$, and the surface $v = 2a\pi x$; here no constant is wanted, because we suppose that when $x = 0$, then $v = 0$.

Since $2a\pi$ is the circumference of a circle whose diameter is a, it follows that *the curve surface of a segment of a sphere is equal to a rectangle contained by a straight line equal to the circumference of the sphere and the height of the segment;* and hence it follows, that *the whole surface of the sphere is four times the area of one of its great circles.* These conclusions were found by Archimedes.

Ex. 2. To find the surface of a paraboloid. Put AQ $= x$, PQ $= y$, arc AP $= z$, curve surface generated by AP $= v$, the parameter $= 2a$. We found (article 160)

$dz = \frac{dy}{a}\sqrt{a^2 + y^2}$, hence,

$$dv = 2\pi y dz = \frac{2\pi}{a}\,ydy\sqrt{a^2 + y^2},$$

and, integrating, $v = \frac{2\pi}{a}\int ydy\sqrt{a^2+y^2} = \frac{2\pi}{3a}(a^2+y^2)^{\frac{3}{2}} + \mathrm{C}$.

When $v = 0$, then $y = 0$; therefore, at the vertex we have

$$0 = \frac{2\pi a^3}{3a} + \mathrm{C}\ \text{and}\ \mathrm{C} = -\frac{2\pi a^3}{3a};$$

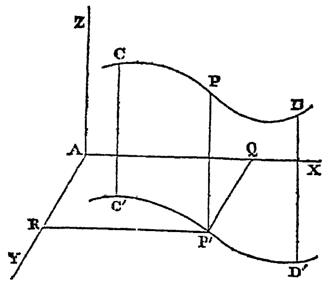
therefore, substituting for C, we have

$$v = \frac{2\pi}{3a}\{(a^2+y^2)^{\frac{3}{2}} - a^3\} = \frac{2}{3}\pi\{\sqrt{a(2x+a)}^3 - a^2\}.$$

Rectification of Curves of Double Curvature.

166. Let CPD be a line of double curvature referred to three co-ordinate planes YAX, ZAX, ZAY. From every point in the curve let perpendiculars PP′, &c. be drawn to one of the planes, YAX; these will all be in the surface of a cylinder that meets the plane in a curve C′P′D, which will be the projection of the proposed curve. Again, from P′ draw P′Q, P′R perpendicular to AX, AY. Let AQ $=$ P′R $= x$, AR $=$ P′Q $= y$, P′P $= z$, the arc CP $= v$, its projection C′P′ $= v'$: Then $dv' = \sqrt{dx^2 + dy^2}$, (art 72). Suppose now the cylindric surface to be extended into a plane surface; the curve CPD will then be changed into a common plane curve, and its projection C′P′D′ into a straight line of the same length as before. We may now consider

Fig. 32.



v' and z as co-ordinates of the curve v, and then $dv = \sqrt{dv'^2 + dz^2}$; therefore, by substituting for dv'^2 its value $dx^2 + dy^2$, we find

$$dv = \sqrt{dx^2 + dy^2 + dz^2}.$$

This is a general formula for the rectification of any line of double curvature. The nature of the line will be expressed by two equations $f(x, y) = 0$, $F(x, z) = 0$. From these we find $dy = Pdx$, $dz = Qdx$, expressions in which P and Q are functions of x only. Thus we have $dv = dx\sqrt{1 + P^2 + Q^2} = dxR$, R being a function of the single variable x. The integral $v = \int Rdx$ may now be found by the ordinary rules.

Integration of Differential Equations of two Variables.

167. Every differential equation of the first order which contains only the single powers of dx and dy, has the form $Mdx + Ndy = 0$, and it expresses the relation which subsists between the variable x, the function y, and its differential co-efficient $\frac{dy}{dx}$. The object of inquiry is to discover, if possible, the primitive equation $f(x, y) = 0$, which by differentiation may produce the proposed differential equation.

168. The method which first presented itself to analysts was to endeavour to separate the variables, so as to give it the form $Xdx + Ydy = 0$, X being a function of x alone, and Y a function of y. When this can be done, the differentials Xdx, Ydy are separately integrable, and we have $\int Xdx + \int Ydy = C$ an arbitrary constant.

Let the equation be $mydx + nxdy = 0$; by dividing its terms by xy, it is changed to $\frac{mdx}{x} + \frac{ndy}{y} = 0$. The variables are now separated, and we have $\int \frac{mdx}{x} + \int \frac{ndy}{y} = m\,l.\,x + n\,l.\,y = C$, or $l.\,(x^m) + l.\,(y^n) = C$, or $l.\,(x^m y^n) = C$. We may suppose $C = l.\,c$, and then $x^m y^n = c$ is the primitive equation.

The variables may be separated when the differential equation has the form $Xdy + Ydx = 0$, X being a function of x, and Y a function of y; for then $\frac{dx}{X} + \frac{dy}{Y} = 0$.

169. The variables may always be separated in *homogeneous equations*, the distinguishing property of which is, that the sum of the exponents of x and y is the same in each of its terms. For example, $ax^m y^n dx + bx^{m-1} y^{n+1} dy$ is a homogeneous equation; because the sum of the exponents of x and y is $m + n$ in each term. Let $Mdx + Ndy = 0$ be a homogeneous equation. Make $y = xz$, then M will take the form Zx^m, and N the form $Z_1 x^m$, Z and Z_1 being functions of z only; and since $dy = zdx + xdz$, the equation will be, after dividing by x^m, $Zdx + Z_1(xdz + zdx) = 0$, a result which may be put under the form

$$\frac{dx}{x} + \frac{Z_1 dz}{Z + zZ_1} = 0;$$

from which we get

$$\int \frac{dx}{x} + \int \frac{Z_1 dz}{Z + zZ_1} = C.$$

170. Ex. 1. Let us apply this transformation to the equation $xdx + ydy = nydx$ or $(x - ny)\,dx + ydy = 0$, which, making $y = xz$, and therefore $dy = xdz + zdx$, becomes $x(1 - nz)\,dx + x^2zdz + xz^2dx = 0$, or $(1 - nz + z^2)\,dx + xzdz = 0$, and $\int \frac{dx}{x} + \int \frac{zdz}{1 - nz + z^2} = C$, or $l.\,x + \int \frac{zdz}{1 - nz + z^2} = C$. This integral may be simplified by observing that

$$\frac{zdz}{1 - nz + z^2} = \frac{1}{2}\,\frac{2zdz - ndz}{1 - nz + z^2} + \frac{1}{2}\,\frac{ndz}{1 - nz + z^2},$$

for it then becomes

$$l.\,x + \tfrac{1}{2}\,l.\,(1 - nz + z^2) + \tfrac{1}{2}\int \frac{ndz}{1 - nz + z^2} = C.$$

The integral which yet remains to be found will depend on logarithms, if $\frac{1}{2}n > 1$; on arcs of circles, if $\frac{1}{2}n < 1$; and will be algebraical if $\frac{1}{2}n = 1$. In each case it may be had by the methods given for integrating rational fractions.

Ex. 2. Let it be proposed to integrate the equation

$$xdy - ydx = dx\sqrt{x^2 + x^2}.$$

By making $y = xz$, bringing all the terms to one side of the equation, and dividing by x, we shall have $dx\sqrt{1 + z^2} - xdz = 0$, and hence

$$\frac{dx}{x} - \frac{dz}{\sqrt{1 + z^2}} = 0;$$

and by the separate integration of each term,

$$l.\,x - l.\,(z + \sqrt{1 + z^2}) = l.\,C, \text{ or } \frac{x}{z + \sqrt{1 + z^2}} = C.$$

and replacing z by its value x, there will result

$$\frac{x^2}{y + \sqrt{x^2 + y^2}} = C, \text{ or } -y + \sqrt{x^2 + y^2} = C;$$

and hence again, by transposing y, and squaring, $x^2 = C^2 + 2Cy$, which is the primitive equation.

The equation

$$(a + mx + ny)\,dx + (b + px + qy)\,dy = 0,$$

which is not homogeneous in its present form, may be transformed so as to become homogeneous. Assume $x = t + \alpha$, $y = u + \beta$, then $dx = dt$, $dy = du$, and the proposed equation becomes

$$(a + m\alpha + n\beta + mt + nu)dt + (b + p\alpha + q\beta + pt + qu)du = 0.$$

To make the constant terms disappear, we assume $a + m\alpha + n\beta = 0$, $b + p\alpha + q\beta = 0$, equations which determine α and β, and then there remains the different equation

$$(mt + nu)\,dt + (pt + qu)\,du = 0,$$

which is homogeneous in respect of the new variables t and u. This transformation gives no result when $mq - np = 0$, a case in which α and β become infinite; but then $q = \frac{np}{m}$; and consequently $m\,(px + qy) = p\,(mx + ny)$. The proposed equation being changed to

$$adx + bdy + (mx + ny)\left(dx + \frac{p}{m}dy\right) = 0,$$

Inverse Method.

we now make $mx + ny = z$, so that $dy = \frac{dz - mdx}{n}$; by substitution and proper reduction our equation now becomes

$$dx + \frac{(bm + pz)\,dz}{amn - bm^2 + m\,(n - p)\,z} = 0.$$

The integral of this equation will contain logarithms, except in the case where $n = p$, when it will be

$$x + \frac{2bmz + pz^2}{2m\,(an - bm)} = \text{C}.$$

171. The separation of the variables is easily effected in the equation $dy + \text{P}ydx = \text{Q}dx$, where P and Q denote any functions whatever of x. Substituting Xz and $z d$X + Xdz instead of y and dy, it becomes

$$z d\text{X} + \text{X}dz + \text{PX}zdx = \text{Q}dx.$$

Here X denotes an indeterminate function of x, to which we may give such a form as shall conduce to the separation of the variables. For this purpose we make $\text{X}dz + \text{PX}zdx = 0$, which requires that $zd\text{X} = \text{Q}dx$. If we divide the first equation by X, it becomes $dz + \text{P}zdx = 0$, from which we deduce $\frac{dz}{z} + \text{P}dx = 0$, and $\text{l}.\,z + \int \text{P}x = 0$; and passing from logarithms to numbers, $z = e^{-\int \text{P}dx}$ (here e is the base of Napier's logarithms), we neglect the arbitrary constant in the mean time, as it will be added at the end of the operation. Afterwards, deducing the value of dX from the second equation, and substituting it in the first, we shall have

$$d\text{X} = e^{\int \text{P}dx}\,\text{Q}dx,\ \text{X} = \int e^{\int \text{P}dx}\,\text{Q}dx + \text{C},$$

and consequently,

$$y = e^{-\int \text{P}dx}\{\int e^{\int \text{P}x}\,\text{Q}dx + \text{C}\}$$

Ex. Let the equation be $dy + ydx = ax^3\,dx$: then $\text{P} = 1, \text{Q} = ax^3, \int \text{P}dx = x, e^{\int \text{P}dx} = e^x, e^{-\int \text{P}dx} = e^{-x}$; $\int e^{\int \text{P}dx}\,\text{Q}dx = \int ae^x\,x^3dx = ae^x\,(x^3 - 3x^2 + 6x - 6)$; therefore $y = e^{-x}\,\{ae^x(x^3 - 3x^2 + 6x - 6) + \text{C}\}$
$= \text{C}e^{-x} + a\,(x^3 - 3x^2 + 6x - 6)$.

172. The early writers on the integral calculus classed differential equations by the number of their terms. In equations which had but two terms, and whose form is consequently $\beta u^g z^h dz = au^e z^f du$, the variables are separated immediately, since we thence deduce $\beta z^{h-f} dz = au^{e-g} du$. This however is not the case with equations of three terms, which are expressed by the formula

$$\gamma u^i z^k\,dz + \beta u^g z^h\,du = au^e z^f du.$$

This may be simplified by dividing the terms by $\gamma u^i z^f$, it then becomes

$$z^{k-f}dz + \frac{\beta}{\gamma}u^{g-i}z^{h-f}du = \frac{\alpha}{\gamma}\,u^{e-i}\,du.$$

Suppose now $z^{k-f}dz = \frac{dy}{k-f+1}$, $u^{g-i}du = \frac{dx}{g-i+1}$; then we have $z^{k-f+1} = y$, $u^{g-i+1} = x$, and

$$dy + \frac{(k-f+1)\beta}{(g-i+1)\gamma}y^{\frac{k-f}{k-f+1}}dx = \frac{(k-f+1)\alpha}{(g-i+1)\beta}x^{\frac{e-g}{g-i+1}}dx.$$

To abridge, let us put

$$b = \frac{(k-f+1)\,\beta}{(g-i+1)\,\gamma},\quad a = \frac{(k-f+1)\,\alpha}{(g-i+1)\,\gamma},$$
$$n = \frac{h-f}{k-f+1},\quad m = \frac{e-g}{g-i+1};$$

and the equation will become

$$dy + by^n dx = ax^m dx.$$

When $n = 1$, the equation belongs to the class treated of in last article. When $n = 2$, the equation is

$$dy + by^2 dx = ax^m dx,$$

which was first considered by an Italian geometer, *Riccati*, whose name it bears. When $m = 0$, the variables are separable, and we have

$$dx = \frac{dy}{a - by^2}.$$

Proceeding from this case, analysts have succeeded in separating the variables when m is any number of the form $\frac{-4i}{2i \pm 1}$, i being supposed an integer number. Riccati's equation was first considered by James Bernoulli, who gave an approximate solution of it. (Jac. Bernoulli *Opera*, p. 1053.) The general problem, however, remains yet unresolved.

173. When a differential equation is the immediate result of the differentiation of a known function, then that function, put equal to C a constant, will be the integral required. The differential equation $xdy + ydx = 0$ is of this class; it is the differential of the product xy, therefore the primitive equation is $xy = \text{C}$. A differential equation may, however, not be the immediate result of the differentiation of a function of x and y; it may be formed by the elimination of some constant quantity contained in the function and also in its differential (art. 54); or it may be the result after the differential of the primitive has been divided by some factor common to all its terms. Thus, if the primitive be $y = cx$, or $y - cx = 0$, the differential equation is $dy - cdx = 0$. If however we eliminate c by the usual algebraic process, we find $xdy - ydx = 0$, an expression which is not the immediate result of any differentiation. The same result will be obtained if the primitive $x = cy$ be put under the form $\frac{x}{y} = c$; for then, by differentiating, $\frac{ydx - xdy}{y^2} = 0$, and, rejecting the factor $\frac{1}{y^2}$, $ydx - xdy = 0$. This expression is not an exact differential; however, it becomes so by restoring the factor $\frac{1}{y^2}$, and then it is the differential of $\frac{x}{y}$.

174. In general let $u = f(x, y)$ be the primitive equation, the differential being $du = \text{M}dx + \text{N}dy$, where M denotes $\frac{du}{dx}$, that is, the differential co-efficient found on the supposition that x is variable and y constant, and N denotes $\frac{du}{dy}$, the co-efficient taken on the reverse hypothesis of y being variable and x constant; now we have found that $\frac{d^2u}{dxdy} = \frac{d^2u}{dydx}$ (art. 89); therefore, if $\text{M}dx + \text{N}dy$ be the differential of $u = f(x, y)$, then

$$\frac{d\text{M}}{dy} = \frac{d\text{N}}{dx}\text{......................}(1)$$

Hence, *If* Mdx + Ndy *is an exact differential, the condition expressed by formula* (1) *will always be satisfied. And, conversely, if* M *and* N *are such functions of* x *and* y *that* $\frac{\text{dM}}{\text{dy}} = \frac{\text{dN}}{\text{dx}}$, *then* Mdx + Ndy *shall be an exact differential, and in every case its integral may be found.* This is called the *Condition of Integrability*.

To prove the second part of the proposition, let us sup-

Inverse Method.

pose that the integral of Mdx is taken on the supposition that in the function M, x is variable and y constant; and let the integral be $P+Y$, where Y is any function of y, which comes in the place of the indeterminate constant that enters into every integral, and P is a known function of x and y, which results from $\int Mdx$ relatively to x only, so that $M=\frac{dP}{dx}$.

The complete differential of $P+Y$ is (art. 91) $\frac{dP}{dx}dx+\frac{dP}{dy}dy+dY$, or $Mdx+\frac{dP}{dy}dy+dY$. By comparing this with the differential $Mdx+Ndy$, it appears that it such a value be given to Y that $Ndy=\frac{dP}{dy}dy+dY$ or that

$$dY=\left(N-\frac{dP}{dy}\right)dy \text{..............(2)}$$

then the integral of $Mdx+Ndy$ will be $P+Y$. Now, by differentiating $M=\frac{dP}{dx}$ in respect of y, we have $\frac{dM}{dy}=\frac{d^2P}{dydx}$, but by hypothesis $\frac{dM}{dy}=\frac{dN}{dx}$, and $\frac{d^2P}{dydx}=\frac{d^2P}{dxdy}$ (art. 89), therefore $\frac{dN}{dx}=\frac{d^2P}{dxdy}$, and $\frac{dN}{dx}-\frac{d^2P}{dxdy}=0$, that is, $d\left(N-\frac{dP}{dy}\right)=0$, the differential being taken supposing x only to be variable; therefore $N-\frac{dP}{dy}$ is constant in respect of x, and is a function of y only; hence the possibility of finding $Y=\int\left(N-\frac{dP}{dy}\right)dy$ is proved, and we have the integral of $Mdx+Ndy$ expressed by $P+\int\left(N-\frac{dP}{dy}\right)dy$, and here $P=\int Mdx$, the integral being taken on the supposition that y is constant.

We may begin with finding the integral of Ndy, supposing x to be constant, proceeding in all respects as has been explained. In general we ought to begin with the term which brings out the integral with least calculation.

Ex. 1. It is proposed to find whether the differential $\frac{ydx-xdy}{x^2+y^2}$ satisfies the condition of integrability, and, if it does, to integrate it.

We put the differential under the form

$$du=\frac{y}{x^2+y^2}dx-\frac{x}{x^2+y^2}dy,$$

therefore $M=\frac{y}{x^2+y^2}$, $N=-\frac{x}{x^2+y^2}$,

$$\frac{dM}{dy}=\frac{x^2-y^2}{(x^2+y^2)^2},\quad \frac{dN}{dx}=\frac{x^2-y^2}{(x^2+y^2)^2}.$$

The condition of integrability is in this case satisfied, and therefore $\frac{ydx-xdy}{x^2+y^2}$ is an exact differential.

To determine the integral, we have

$$P=\int Mdx=\int\frac{ydx}{x^2+y^2}=\int\frac{\frac{dx}{y}}{1+\frac{x^2}{y^2}}=\tan^{-1}\frac{x}{y},$$

whence $u=\tan^{-1}\frac{x}{y}+Y$.

Differentiating, and considering the whole as variable,

$$du=\frac{ydx-xdy}{x^2+y^2}+dY.$$

This, compared with the proposed differential, shows that $dY=0$, and $Y=C$ a constant.

Ex. 2. To find the integral of the differential

$$du=(2y^2x+3y^3)\,dx+(2x^2y+9xy^2+8y^3)\,dy.$$

In this example, $M=2y^2x+3y^3$, $N=2x^2y+9xy^2+8y^3$,

$$\frac{dM}{dy}=4yx+9y^2=\frac{dN}{dx};$$

the proposed function is therefore a complete differential.

Integrating in respect of x, we find

$$\int Mdx=y^2x^2+3y^3x+Y,$$

and $u=y^2x^2+3y^3x+Y$.

Differentiating this expression in respect of y,

$$\frac{du}{dy}=2x^2y+9xy^2+\frac{dY}{dy},$$

but we had $\frac{du}{dy}=2x^2y+9xy^2+8y^3$;

therefore, $\frac{dY}{dy}=8y^3$, and $Y=\int 8y^3dy=2y^4+C$,

and consequently the integral is

$$u=y^2x^2+3y^3x+2y^4+C.$$

175. If in the equation $Mdx+Ndy=0$, the condition of integrability, viz. $\frac{dM}{dy}=\frac{dN}{dx}$, is not satisfied, we may next inquire whether some factor, a function of x and y, can be found by which the expression $Mdx+Ndy$ can be rendered a complete differential.

Let the equation be put under the form $\frac{dy}{dx}+K=0$, where $K=\frac{M}{N}$. This equation is the result of the elimination of a constant quantity c between a primitive equation, which may be represented by $f(x,y,c)=0$ and its immediate differential. Or else c may be eliminated directly by bringing the primitive equation to the form $F(x,y)=c$, which will lead to the same result (art 53). Put u for $F(x,y)$, also Pdx for the differential of u taken relatively to x, and Qdy for its differential relatively to y, so that $du=Pdx+Qdy$, and $\frac{du}{dx}=P+Q\frac{dy}{dx}=0$, therefore $P+Q\frac{dy}{dx}=0$. Since this equation does not contain C, it ought to be identical with the equation $\frac{dy}{dx}+K=0$;

therefore $\frac{dy}{dx}+K=\frac{dy}{dx}+\frac{P}{Q}=\frac{Pdx+Qdy}{Qdx}$, that is, $\frac{dy}{dx}+K=\frac{du}{Qdx}$, and hence

$$Q(dy+Kdx)=du.$$

Now the second side of the equation is a complete integral; hence it appears that *there is always a factor* Q, *by which, if the differential equation* dy + Kdx = 0 *be multiplied, the result will be a complete integral.*

Let both sides of the equation be multiplied by U, any function of U, and we have

$$UQ(dy+Kdx)=Udu.$$

Now Udu is still a complete differential, and as the factor UQ may have an infinite variety of forms, it follows that *there are an infinite number of factors, such that if a differential equation be multiplied by any one of them, it will be a complete differential.*

Since it appears that when the equation $Mdx + Ndy = 0$ does not satisfy the condition of integrability, it is because differentiation and subsequent elimination of the arbitrary constant have caused a factor to disappear, which, if it were known and restored, would render the expression a complete differential, the discovery of that factor is a most important problem in the calculus. Its solution, however, transcends the present powers of analysis, although it can be resolved in particular cases. When the functions M and N are homogeneous, the factor can be found; but that case can always be integrated as has been explained. When the variables can be separated, a multiplier can be found, but then it is not wanted. It can also be found when the equation has the form $dy + Pydx = Qdx$; but this also can be integrated by other means.

Euler, who has entered deeply into this subject, has reversed the problem; and, in his *Calculus Integralis*, supposing the integrating factor given, has investigated the nature of the functions which must enter into a differential equation of a given form, in order that it may be integrable. These investigations, however, frequently lead to differential equations, which cannot be integrated by any known method; and the cases in which they are successful are of no great importance or extent.

176. Let M be any function of x and y, and let $u = \int Mdx$, the integral being taken on the supposition that x is variable and y constant: it is sometimes required that the differential co-efficient $\frac{du}{dy}$ be found; or, in other words, that the differential of $\int Mdx$ relatively to y be found without having actually integrated the expression relatively to x. Because $u = \int Mdx$, therefore $\frac{du}{dx} = M$, and $\frac{d^2u}{dxdy} = \frac{dM}{dy}$; but $\frac{d^2u}{dxdy} = \frac{d^2u}{dydx}$ (art. 89), therefore $\frac{d^2u}{dydx} = \frac{dM}{dy}$, and $\frac{d^2u}{dy} = \frac{dM}{dy}dx$, and integrating relatively to x, $\frac{du}{dy} = \int \frac{dM}{dy}dx$.

Ex. Let $u = \int \frac{ydx}{\sqrt{y^2 - x^2}}$, here $M = \frac{y}{\sqrt{y^2 - x^2}}$, and $\frac{dM}{dy} = \frac{-x^2}{(y^2 - x^2)^{\frac{3}{2}}}$, and $\frac{du}{dy} = \int \frac{-x^2dx}{(y^2 - x^2)^{\frac{3}{2}}}$.

The theorem investigated in this article was found by Leibnitz, and was reckoned an important discovery in the calculus. (See Bossut, *Traité du Calcul Diff.* &c. vol. ii, p. 58.)

177. The elimination of a constant contained in a primitive equation may introduce the second or higher powers of the differentials into the resulting differential equation (art. 53): in such cases we must find the values of $\frac{dy}{dx}$ by the resolution of an equation.

For example, if $dy^2 - a^2dx^2 = 0$, or $\frac{dy^2}{dx^2} = a^2$, we have $\frac{dy}{dx} = \pm a$ and $dy + adx = 0$, also $dy - adx = 0$; therefore $y + ax + c = 0$ and $y - ax + c' = 0$ are two primitive equations, from each of which the differential equation may be derived; also from their product $(y + ax + c)(y - ax + c') = 0$.

178. When the equation contains only one of the variables, x for example, we deduce from it $\frac{dy}{dx} = X$, and $y = \int Xdx$; but if the equation be more easily resolvable with respect to x than with respect to the co-efficient $\frac{dy}{dx}$, which we will represent by p, and if we have also $x = P$, a function of p, and thence $dx = dP$; then, since $dy = pdx$, therefore $dy = pdP$, and $y = pP - \int Pdp$. The relation between x and y is now to be found by eliminating p by means of the equations

$$x = P, \ y = Pp - \int Pdp.$$

Let us take as an example $xdx + ady = b\sqrt{dx^2 + dy^2}$, or $x + ap = b\sqrt{1 + p^2}$, by writing p in the place of $\frac{dy}{dx}$. This last equation gives immediately $x = -ap + b\sqrt{1 + p^2}$, and consequently

$$y = bp\sqrt{1 + p^2} - \tfrac{1}{2}ap^2 - b\int dp\sqrt{1 + p^2}.$$

179. When the primitive equation cannot be deduced from the differential equation by any of the known artifices of analysis, then, as a last resource, recourse must be had to approximation by infinite series.

Ex. Let the differential equation be $dy + ydx = mx^ndx$, and suppose it to be known that when $x = a$, then $y = b$: we now make $x = a + t$, $y = b + u$, the equation by this transformation becomes $du + (b + u)dt = m(a + t)^ndt$. We now assume that

$$u = At^\alpha + Bt^{\alpha+1} + Ct^{\alpha+2} + \&c.$$

and hence, putting instead of u and du their values, and bringing the terms to one side, we have

$$\left.\begin{array}{l} \alpha At^{\alpha-1} + (\alpha + 1)Bt^\alpha + (\alpha + 2)Ct^{\alpha+1} + \&c. \\ + b \quad + \quad At^\alpha \quad + \quad Bt^{\alpha+1} + \&c. \\ - ma^n - m\frac{n}{1}a^{n-1}t - m\frac{n(n-1)}{1.2}a^{n-2}t^2 - \&c. \end{array}\right\} = 0.$$

In this equation we must suppose $\alpha - 1 = 0$, and we shall then find

$$A = ma^{n-1} - b, \ B = \frac{mna^{n-1} - ma^n + b}{1.2},$$
$$C = \frac{mn(n-1)a^{n-2} - mna^{n-1} + ma^n - b}{1.2.3}, \ \&c.$$

These values being substituted in the series, we have u expressed by t and known quantities; we may then put $x - a$ for t, and $y - b$ for u, and the result will express the relation between x and y.

In the series assumed for the value of u, the exponents of t form an arithmetical progression, of which the common difference is 1. In many cases, however, the common difference will be a fraction, as in this example, $(dx + dy)y = dx$. Here we assume

$$y = Ax^a + Bx^b + Cx^c + \&c.$$

By proceeding as before, there is obtained

$$\left.\begin{array}{llll} A^2ax^{2a-1} & + ABax^{a+b-1} + ACax^{a+c-1} + \&c. & & \\ & + ABbx^{a+b-1} + B^2bx^{2b-1} + \&c. & & \\ & \qquad + AC\,cx^{a+c-1} + \&c. & & \\ -1 & + Ax^a \qquad + Bx^b \qquad + \&c. & & \end{array}\right\} = 0.$$

Hence $2a - 1 = 0$, $a + b - 1 = a$, $a + c - 1 = b$, &c.; therefore $a = \frac{1}{2}$, $b = 1$, $c = \frac{3}{2}$, &c.

Again, $A^2a = 1$, $AB(a + b) + A = 0$, &c.

Hence $A = \sqrt{2}$, $B = -\frac{2}{3}$, $C = \frac{1}{18}\sqrt{2}$, &c.

and $y = x^{\frac{1}{2}}\sqrt{2} - \frac{2}{3}x^{\frac{2}{2}} + \frac{1}{18}x^{\frac{3}{2}}\sqrt{2} - \&c.$

On the integration of differential equations by series, consult Euler, *Instit. Cal. Integ.* vol. i. sect. 2; Lacroix, *du Calcul Diff.* part ii. chap. 6.

Inverse Method.

Differential Equations of the Second and Higher Orders.

180. The difficulty of the integrations becomes so much the greater the higher the order of the differential co-efficients which they involve, and we only succeed in effecting it in a very small number of very limited equations.

Let the expression

$$f(x, y, c, c') = 0 \ldots\ldots\ldots\ldots\ldots\ldots(1)$$

represent any primitive equation composed of the variables x, y, and two constant quantities c, c', besides any other constants. By differentiation (as explained art. 48–54), there is formed its differential equation of the first order, which will contain $\frac{dy}{dx}$. Let this differential co-efficient be represented by p, and let $q = \frac{dp}{dx} = \frac{d^2y}{dx}$. The differential of the first order will contain x, y, p, c, c', and may be represented by

$$f'(x, y, p, c, c') = 0 \ldots\ldots\ldots\ldots\ldots\ldots(2)$$

By differentiating this equation we obtain another which contains also $\frac{d^2y}{dx^2} = q$, and may be expressed by

$$f''(x, y, p, q, c, c') = 0 \ldots\ldots\ldots\ldots\ldots\ldots(3)$$

Since these three equations must hold true at once, we may eliminate the constants c, c', and the result will be a single equation,

$$F(x, y, p, q) = 0 \ldots\ldots\ldots\ldots\ldots\ldots(4)$$

in which c, c' are not found. This will be the differential equation of the second order, deducible from the primitive (1), and which is independent of the constants c, c'.

We may arrive at the very same equation (4) in two other ways. We may give the primitive (1) these forms:

$$\varphi(x, y, c) = c', \quad \psi(x, y, c') = c,$$

from which, by differentiation, two results will be obtained, one entirely free from c', and the other from c: these again may have the forms

$$\varphi'(x, y, p) = c, \quad \psi'(x, y, p) = c'.$$

By taking now the differentials of these equations, we shall obtain the very same equation from each, which will be identical with equation (4).

For example, let the primitive equation be

$$x^2 - 2ax + 2by = 0,$$

in which a and b represent the constants c, c'; by differentiation, we find

$$x - a + b\frac{dy}{dx} = 0, \quad 1 + b\frac{d^2y}{dx^2} = 0.$$

After eliminating a and b by the three equations, we have this differential equation,

$$2y - 2x\frac{dy}{dx} + x^2\frac{d^2y}{dx^2} = 0.$$

We may otherwise put the primitive equation under these forms:

$$\frac{x^2 + 2by}{x} = 2a, \quad \frac{x^2 - 2ax}{y} = -2b.$$

Taking now the differentials, and arranging the results so that the constants may stand alone, and putting p instead of $\frac{dy}{dx}$, we have

$$\frac{x^2}{y - xp} = 2b, \quad \frac{2xy - x^2p}{y - xp} = 2a.$$

By differentiating either of these, the constants disappear, and in each case the result is the same, viz.

$$2y - 2x\frac{dy}{dx} + x^2\frac{d^2y}{dx^2} = 0.$$

181. Since two of the constants in a primitive equation may not be found in the differential equation of the second order derived from it, so, reversely, in returning from a differential equation of the second order to its absolute primitive, *the latter cannot be complete unless it contain two arbitrary constants, which are not in the former;* and as the same differential equation of the second order may be obtained from two distinct differential equations of the first order, it follows that *every differential equation of the second order has two distinct differential equations of the first order, each having its own arbitrary constant; and these again have one and the same absolute primitive equation.* The properties of differential equations of the third and higher orders are perfectly analogous to these.

Inverse Method.

182. The most simple differential equation of the second order is $\frac{d^2y}{dx^2} = X$, a function of x; then $\frac{dy}{dx} = \int X dx$. Let P be the variable part of the integral $\int X dx$, and c the constant, so that $\frac{dy}{dx} = P + c$; hence again $dy = Pdx + cdx$, and by a second integration, $y = \int Pdx + cx + c'$. Since $\int Pdx = Px - \int xdP = x\int Xdx - \int xXdx$, therefore,

$$y = x\int Xdx - \int xXdx + cx + c'.$$

The primitive of the differential equation $d^3y - Xdx^3 = 0$ may be found in the same way. We first put it under the form $\frac{d^3y}{dx^2} = Xdx$; then we have by a first integration $\frac{d^2y}{dx^2} = \int Xdx = P + c$; and hence $\frac{d^2y}{dx} = Pdx + cdx$; by a second integration, $\frac{dy}{dx} = \int Pdx + cx + c' = P' + cx + c$; here $P' = \int Pdx$. We have now $dy = P'dx + cxdx + c'dx$; and lastly, $y = \int P'dx + \frac{1}{2}cx^2 + c'x + c''$. The primitive thus containing three arbitrary constants: a like differential equation of the fourth order would contain four, and so on.

183. When a differential equation of the second order involves $\frac{dy}{dx}$ and $\frac{d^2y}{dx^2}$, and constants; if we put $\frac{dy}{dx} = p$, then, regarding dx as constant, $\frac{d^2y}{dx^2} = \frac{dp}{dx}$; the equation will now involve p, dp, dx and constants; and it will be of the first order, in respect of p and x. We may thence find $dx = Pdp$, P being here put for some function of p; and since $dy = pdx = Ppdp$, we have

$$x = \int Pdp, \quad y = \int Ppdp.$$

These integrals being found, and a constant added to each, by eliminating p, we find an equation expressing the relation between x and y.

Ex. To integrate the equation $\frac{(dx^2 + dy^2)^{\frac{3}{2}}}{dxd^2y} = a$. By putting pdx for dy, and $dpdx$ for d^2y, the equation is changed to $\frac{(1+p^2)^{\frac{3}{2}}dx}{dp} = a$, from which we deduce

$$dx = \frac{adp}{(1 + p^2)^{\frac{3}{2}}}, \quad dy = pdx = \frac{apdp}{(1 + p^2)^{\frac{3}{2}}}.$$

The integration gives

$$x = c + \frac{ap}{\sqrt{1 + p^2}}, \quad y = c' - \frac{a}{\sqrt{1 + p^2}}.$$

Hence $(c - x)^2 + (y - c')^2 = a^2$.

The proposed differential equation is nothing more than the general expression of the radius of curvature (art. 78) made equal to a constant quantity a. We have resolved the geometrical problem, to find a curve whose radius of

Inverse Method.

curvature is a constant, and found it to be a circle, as was obvious.

184. We may remark, that the equation $x = C + \int \frac{dp}{P}$, and $dy = C' + \int \frac{pdp}{P}$, severally satisfy the differential equation $\frac{dp}{dx} = P$; and that, by supposing their second members integrated, they will be only of the first order. This agrees with what was observed, art. 181, viz. that there are two equations of the first order which satisfy a differential equation of the second order.

185. Let us now consider differentials of the form $\frac{d^2y}{dx^2} = Y$, Y representing any function of y. If we make $dy = pdx$, we thence deduce $dx = \frac{dy}{p}$, which gives $\frac{d^2y}{dx^2} = \frac{dp}{dx} = \frac{pdp}{dy}$. Substituting this in the proposed equation, there results from it $pdp = Ydy$; by integrating, we find $p^2 = 2\int Ydy$, C, and hence

$$p = \frac{dy}{dx} = \sqrt{C + 2\int Ydy}, \text{ and } x = \int \frac{dy}{\sqrt{C + 2\int Ydy}} + C'.$$

It is proper to observe that the above integration may be effected by multiplying the proposed equation by dy, for thence we find $\frac{dy}{dx} \cdot \frac{d^2y}{dx} = Ydy$; and since $\frac{d^2y}{dx} = d\frac{dy}{dx}$, we have $\frac{1}{2}\frac{dy^2}{dx^2} = \int Ydy + C$, or $\frac{dy}{dx} = \sqrt{2\,C + 2\int Ydy}$.

Ex. Let the equation be $d^2y\sqrt{ay} = dx^2$; we shall have

$$\frac{d^2y}{dx^2} = \frac{1}{\sqrt{ay}}, \quad \frac{dy}{dx} \cdot \frac{d^2y}{dx} = \frac{dy}{\sqrt{ay}},$$

and, by integrating, $\frac{1}{2}\frac{dy^2}{dx^2} = \frac{2}{a}\sqrt{ay} + C$; changing C into $\frac{2c}{\sqrt{a}}$, we shall deduce from thence

$$\frac{dy^2}{dx^2} = \frac{4}{\sqrt{a}}(\sqrt{y} + c), \quad \frac{2dx}{\sqrt[4]{a}} = \frac{dy}{\sqrt{c + \sqrt{y}}}.$$

Now, making $c + \sqrt{y} = z$, there will result

$$\frac{dx}{\sqrt[4]{a}} = \frac{(z-c)}{\sqrt{z}}\,dz = (z^{\frac{1}{2}} - cz^{-\frac{1}{2}})dz;$$

and finally,

$$\frac{x}{\sqrt[4]{a}} = \tfrac{2}{3}z^{\frac{3}{2}} - 2cz^{\frac{1}{2}} + c' = \tfrac{2}{3}(\sqrt{y} - 2c)\sqrt{c + \sqrt{y}} + c'.$$

186. We have seen in the differential calculus, art. 93, that beyond the first order the form of the differential equations would be changed, according as x or y, or even a function of these quantities, was assumed as the *independent variable*; which comes to the same thing as assuming that dx, or dy, or a given function of these variables, was constant. It is therefore necessary, in integrating equations which exceed the first degree, to know upon which of these hypotheses it has been calculated. The preceding examples all correspond to the case of y being a function of x, and consequently of dx being constant; but it will be easy to discover, among relations deduced relatively to other hypotheses, to which of them they may be referred.

It is immediately evident that, if we represent by Q any function whatever of $\frac{dx}{dy}$, every equation of the form $\frac{d^2x}{dy^2} = Q$, and in which dy is constant, may be treated in the same way as that in art. 183, by making $\frac{dx}{dy} = q$, and $\frac{d^2x}{dy^2} = \frac{dq}{dy}$. It may also be reduced immediately to the form $\frac{d^2y}{dx^2} = P$, by passing by the formula of art. 93, to the hypothesis of dx being constant, which will be effected by the substitution of $\frac{-dxd^2y}{dy^3}$ in place of $\frac{d^2x}{dy}$.

Inverse Method.

If the proposed equation had been taken on the supposition of $\sqrt{dx^2 + dy^2}$ being constant, and if it involved only dx, dy, d^2y, or dy, dx, dx^2, it might still be treated in the same manner as that of art. 183, after transforming it into one in which dx was constant.

187. When the equation contains $\frac{d^2y}{dx^2}$, $\frac{dy}{dx}$ and the variable x, it may, as before, be transformed into a differential equation of the first order, by substituting pdx for dy, and $dpdx$ for d^2y; then, if the primitive of that differential equation, and thence the value of p in terms of x, can be found, we may have the value of y from the formula $y = \int pdx$; or else, if we have the value of x in terms of p, then, because $\int pdx = px - \int xdp$, we shall have $y = px - \int xdp$.

Ex. Let the equation be

$$-\frac{(dx^2 + d^2y)^{\frac{3}{2}}}{dxd^2y} = X \text{ or } -\frac{(1+p^2)^{\frac{3}{2}}dx}{dp} = X,$$

where x denotes a given function of x; then

$$\frac{dx}{X} = \frac{-dp}{(1+p^2)^{\frac{3}{2}}} \text{ and } \int \frac{dx}{X} + C = \frac{-p}{\sqrt{1+p^2}}.$$

Let V represent $\int \frac{dx}{X} + C$, then $p = \frac{V}{\sqrt{1 - V^2}}$, and $y = \int pdx + C' = \int \frac{Vdx}{\sqrt{1 - V^2}} + C'$; y is now expressed by means of x only. This is the analytical solution of the geometrical problem to find the nature of a curve whose radius of curvature shall be a given function of x, the absciss.

If we suppose $X = \frac{a^2}{2x}$, then $\frac{-p}{\sqrt{1+p^2}} = \int \frac{2xdx}{a^2} = \frac{x^2}{a} + C$,

$$p^2 = \frac{dy^2}{dx^2} = \frac{x^2 + c}{a^4 - (x^2 + c^2)^2} \text{ and } y = \int \frac{(x^2 + c)dx}{\sqrt{\{a^4 - (x^2 + c)^2\}}};$$

here c is put generally for an indeterminate constant. This is the equation of the elastic curve.

188. If the proposed differential equation is composed of $\frac{d^2y}{dx^2}$, $\frac{dy}{dx}$, and y, we may, as before, put $p = \frac{dy}{dx}$, from which we get $\frac{d^2y}{dx^2} = \frac{dp}{dx} = \frac{pdp}{dy}$; the equation will now involve dp, dy, p and y only. When the primitive equation can be found, and thence the value of p in terms of y, we may find x by the formula $x = \int \frac{dy}{p}$; but when y is expressed by p, we may then employ the formula $x = \frac{y}{p} + \int \frac{ydp}{p^2}$.

189. Differentials of the second order, which have this form,

$$\frac{d^2y}{dx^2} + P\frac{dy}{dx} + Qy = R,$$

in which P, Q, R are any functions of x, are called *linear*, also equations of the *first degree*, because y is only of one dimension. It will easily be understood that the difficulty of finding the primitive equation will be greater than in the like equation of the first order; and, indeed, except in particular cases, there is no known method of reducing the integration to the finding of the differential of a single variable; that is, to the quadrature of a curve. If $R=0$, in which case the equation is

$$\frac{d^2y}{dx^2}+P\frac{dy}{dx}+Qy=0,$$

it may be reduced to a differential equation of the first degree, by a very simple transformation. Let e, as usual, denote the base of Napier's logarithms; assume $y=e^{\int udx}$, then, regarding dx as constant, we have

$$dy=udxe^{\int udx},\ d^2y=e^{\int udx}\ (dudx+u^2dx^2):$$

the value of dy and d^2y being substituted in the equation, and the common factors rejected, it becomes

$$du+(u^2+Pu+Q)\,dx=0.$$

When P and Q are constants, which may be represented by A and B, the equation becomes

$$du+(u^2+Au+B)\,dx=0;$$

in which the variables are separated, if we give it the form

$$\frac{du}{u^2+Au+B}+dx=0.$$

As it is merely necessary to satisfy this equation, we may make $u=m$, m being any constant; then $du=0$, and $m^2+Am+B=0$. This last equation gives, in general, two values of m; if we represent them by a and b, we shall have two values of $\int udx$; viz. $ax+c$ and $bx+c'$, and hence we have two values of y, viz.

$$y=e^{ax+c},\quad y=^{bx+c'};$$

or, putting C for e^c, and C′ for $e^{c'}$,

$$y=Ce^{ax},\quad y=C'e^{bx}.$$

These, however, are only *particular* values of the function y, because each contains only a single arbitrary constant; but by adding them, we get

$$y=Ce^{ax}+C'e^{bx}$$

as the complete primitive equation.

To prove this, by differentiating, we get

$$\frac{dy}{dx}=aCe^{ax}+bC'e^{bx},\ \frac{d^2y}{dx^2}=a^2Ce^{ax}+b^2C'e^{bx}.$$

From these and the above primitive equation, we have, after eliminating C and C′,

$$\frac{d^2y}{dx^2}+(a+b)\frac{dy}{dx}-aby=0.$$

This will agree with the proposed equation, if we give a and b such values that $a+b=P$, $ab=-Q$.

If a and b come out impossible quantities, the exponents of a and b in the value of y will have the form

$$a=\alpha+\beta\sqrt{-1},\ b=\alpha-\beta\sqrt{-1};$$

we have then

$$y=Ce^{\alpha x+\beta x\sqrt{-1}}+C'e^{\alpha x-\beta x\sqrt{-1}}$$
$$=e^{\alpha x}\left(Ce^{\beta x\sqrt{-1}}+C'e^{-\beta x\sqrt{-1}}\right);$$

This result is rendered real by eliminating the imaginary quantities, by means of sines and cosines; thus we have (ALGEBRA, art. 269),

$$e^{\beta x\sqrt{-1}}=\cos\beta x+\sqrt{-1}\sin\beta x,$$
$$e^{-\beta x\sqrt{-1}}=\cos\beta x-\sqrt{-1}\sin\beta x,$$
$$y=e^{\alpha x}\{(C+C')\cos\beta x+(C-C')\sqrt{-1}\sin\beta x\};$$

and making $C+C'=c$, $(c-c')\sqrt{-1}=c'$,

$$y=e^{\alpha x}\,(c\cos\beta x+c'\sin\beta x);$$

or, making $c=p\sin q$, $c'=p\cos q$,

$$y=pe^{\alpha x}\sin(\beta x+q).$$

When the roots a and b are equal, the value of y being reduced to

$$Ce^{ax}+C'e^{ax}=(C+C')e^{ax},$$

it becomes incomplete. In this case we may proceed, as in art. 58, by supposing that a and b differ by a very small quantity. Let us suppose that $b=a+k$, there thence results

$$y=Ce^{ax}+C'e^{ax+kx}=e^{ax}(C+C'e^{kx}):$$

developing e^{kx} according to the powers of k, we have

$$y=e^{ax}(C+C'+C'kx+C'\frac{k^2x^2}{2}+\&c.)$$

or, putting $C+C'=c$ and $c'k=c'$

$$y=e^{ax}(c+c'x+c'k\frac{x^2}{2}+\&c.)$$

This last expression, which satisfies the proposed equation for all values of k, agrees with it likewise if $k=0$, or $b=a$; and, in that case, it becomes

$$y=e^{ax}(c+c'x).$$

190. When P and Q are variable quantities, functions of x, then if v and v' are two values of y which each satisfy the equation

$$\frac{d^2y}{dx^2}+P\frac{dy}{dx}+Qdy=0,$$

we may take

$$y=cv+c'v$$

for the complete primitive equation. For then $dy=cdv+cdv'$, $d^2y=cd^2v+cd^2v$, and the differential equation becomes

$$c\left(\frac{d^2v}{dx^2}+P\frac{dv}{dx}+Qv\right)+c,\left(\frac{d^2v}{dx^2}+\frac{dv'}{dx}+Qv'\right)=0.$$

Now, by hypothesis,

$$\frac{d^2v}{dx^2}+P\frac{dv}{dx}+Qv=0;\ \frac{d^2v'}{dx^2}+P\frac{dv'}{dx}+Qdv'=0.$$

Therefore the equation is identical, and so the value of y is truly determined.

As an example of the integration of a differential equation of the second degree, see the article ARCH (art. 57).

191. We shall now give an example of the integration of a differential equation of the first degree and the second order.

Let the equation be

$$d^2y+ax^nydx^2=0.$$

If we suppose

$$y=Ax^\alpha+Bx^{\alpha+\delta}+Cx^{\alpha+2\delta}+\&c.$$

and that the series of exponents is an increasing one, or that δ is positive, we may, when x is supposed very small, conceive y to reduce itself to its first term, since the others are too small to be compared with this first. On this supposition, we may confine ourselves to assuming

$$y=Ax^\alpha;\text{ then }d^2y=\alpha(\alpha-1)Ax^{\alpha-2}dx^2,$$

and the proposed equation will become

$$\alpha(\alpha-1)Ax^{\alpha-2}+aAx^{\alpha+n}=0.$$

It is not possible to determine α so as to make the two exponents $\alpha-2$ and $\alpha+n$ equal, except in the particular case of $n=-2$; but the exponent of x being greater in the second term than the first, we may neglect one of these terms in comparison with the other; and the equation may then be verified in two ways (by approxi-

Inverse Method.

mation), viz. by making $\alpha = 0$, and $\alpha = 1$, since upon either hypothesis the term $\alpha(\alpha - 1)\, Ax^{\alpha - 2}$ (the greatest in the equation) vanishes: A, therefore, remains indeterminate, and we have two series, one beginning with A, and the other with Ax.

If we take successively

$$y = A + Bx^{\delta} + cx^{2\delta} + \&c.$$
$$y = Ax^{1+\delta} + Bx^{1+2\delta} + cx^{1+2\delta} + \&c.$$

and substitute for y these values, and for d^2y its corresponding values, we shall then find, by properly arranging the terms, that δ must be $= 2$; and, in either case, determining the values of the co-efficients A, B, C, &c. we arrive at these two series,

$$A - \frac{aAx^{n+2}}{(n+1)(n+2)} + \frac{a^2Ax^{2n+4}}{(n+1)(n+2)(2n+3)(2n+4)} - \frac{a^3Ax^{3n+6}}{(n+1)(n+2)(2n+3)(2n+4)(3n+5)(3n+6)} + \&c.$$

$$Ax - \frac{aAx^{n+3}}{(n+2)(n+3)} + \frac{a^2Ax^{2n+5}}{(n+2)(n+3)(2n+4)(2n+5)} - \frac{a^3A^{3n+7}}{(n+2)(n+3)(2n+4)(2n+5)(3n+6)(3n+7)} + \&c.$$

These developments are only particular cases, since they contain each but one arbitrary constant A; but, on account of the particular form of the proposed example (189), we shall obtain a general expression for y, by writing in the latter of them A_1 for A, and taking their sum.

Having now given as full a view of the principles of the fluxional calculus as we conceive to be compatible with the nature of our work, we shall conclude with a few more examples of its application to geometry.

Problem 1.

To find the length of the enlarged meridian in *Mercator's*, or rather *Wright's* projection of the sphere.

In this projection, the meridians and parallels of latitude are straight lines, which intersect each other at right angles; and the projection of any small arc of a meridian (as one minute), reckoned from any parallel, is to the projection of a like arc of longitude in that parallel, as radius to the cosine of the latitude of the parallel, that is, in the same ratio as the arcs themselves in the sphere. Supposing the radius of the sphere to be unity, let v be any arc of latitude reckoned from the equator, z its projection on the chart, or the *enlarged meridian.* Let v' and z' be any small increments of v and z; then, by the principles of the projection, $\frac{z'}{v'} = \frac{rad}{\cos v}$; therefore, putting the ratio of the differentials for the limit of the ratio of the increments, $\frac{dz}{dv} = \frac{1}{\cos v}$, and $dz = \frac{dv}{\cos v}$. Therefore, taking the integral (art. 155), $z = \text{l.}\left\{\tan\left(45° + \tfrac{1}{2}v\right)\right\}$. Here no correction is wanted, because when $v = 0$, then $z = \text{l.}(\tan 45°) = \text{l.}(1) = 0$, as it should be.

Henry Bond, in the year 1650, discovered, by chance, that the enlarged meridian might be expressed by the logarithmic tangents of half the complements of the latitudes, a rule easily found from the preceding solution; but the difficulty of proving this was then considered so great, that Mercator offered to wager a sum of money against any person that should undertake to prove it either true or false. James Gregory, however, proved it in his *Exercitationes Geometricæ*, published in 1668; also Barrow, in his Geometrical Lectures: their demonstrations, however, were intricate. Afterwards Dr Wallis and Dr Halley gave demonstrations which were sufficiently simple and elegant.

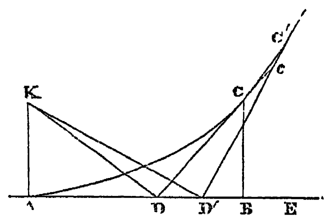
Problem 2.

If any number of straight lines are drawn according to some determinate law, it is required to find the nature of a curve to which these are tangents.

For example, let AE be a straight line given by position, and K a given point without it; let any number of lines KD, KD′, &c. be drawn to meet AE in D, D′, &c.; and let perpendiculars DC, D′C′, &c. be drawn to these lines; it is required to find the nature of the curve ACC′, to which these perpendiculars are tangents.

Without attending to the particular case, we shall resolve the general problem, and suppose AE to be the axis of

Fig. 33.



the curve, A being the origin of the co-ordinates, and CD any position of the tangent, which meets the axis in D. From the point of contact C draw the perpendicular CB; and, considering C as a point in the curve, put $AB = x$, $BC = y$; but again considering C as any point whatever in the tangent, put $AB = x'$, $BC = y'$. Then, whatever be the conditions that determine the position of the tangent, the relation of x' and y', the co-ordinates of any point in it, may be expressed by the equation $y' = Px' + Q$, where P and Q are put to denote generally certain functions of constant quantities, and some quantity p, which has the same value for any given position of the tangent, but which changes its value if the tangent changes its position. For example, p may express the angle which the tangent makes with the axis, or it may represent the subtangent BD, &c.

Let us now suppose that the variable quantity p changes its value, and becomes $p + h$, and that C′ D′ is the new position of the tangent corresponding to $p + h$; then, considering P and Q as functions of p, by Taylor's theorem (art. 31),

$$\text{P becomes } P + \frac{dP}{dp}h + \frac{d^2P}{dp^2}\frac{h^2}{2} + \&c.$$
$$\text{Q becomes } Q + \frac{dQ}{dp}h + \frac{d^2Q}{dp^2}\frac{h^2}{2} + \&c.$$

The relation of x' to y' in the new position of the tangent will now be expressed by the equation

$$y' = Px' + Q + \left(\frac{dP}{dp}x' + \frac{dQ}{dp}\right)h + Kh^2 + \&c.$$

Where Kh^2 + &c. is put for all the remaining terms of the series.

Now, as this equation holds true of every point in the

tangent C′D′, and the equation $y' = \mathrm{P}x' + \mathrm{Q}$ holds true of every point in the tangent CD, it follows that at c, the intersection of the two tangents, both equations must be true at the same time; therefore at c we have

$$\left(\frac{d\mathrm{P}}{dp}x' + \frac{d\mathrm{Q}}{dp}\right)h + \mathrm{K}h^2 + \&\text{c.} = 0;$$

and, dividing by h, $\dfrac{d\mathrm{P}}{dp}x' + \dfrac{d\mathrm{Q}}{dp} + \mathrm{K}h + \&\text{c.} = 0.$

Conceive now the two tangents to approach to coincidence; when C′ comes to C, then c will also fall at C; and h, and all the terms into which it enters, vanish; also x' and y' become x and y: and, to determine the nature of the curve, we have these two equations:

$$y = \mathrm{P}x + \mathrm{Q} \text{.......................................} (1)$$

$$0 = \frac{d\mathrm{P}}{dp}x + \frac{d\mathrm{Q}}{dp} \text{.................................} (2)$$

By eliminating p from these, the resulting equation will express the nature of the curve.

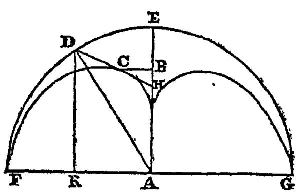
Ex. 1. Let us now recur to the particular case of AE, a straight line given by position, K a given point, and KDC a right angle: Draw KA perpendicular to AE; put $\mathrm{AB} = x$, $\mathrm{BC} = y$, $\mathrm{KA} = a$, and let AD be the variable quantity p. The triangles KAD, DBC are manifestly similar; therefore KA : AD = DB : BC, that is, $a : p = x - p : y$; hence $ay = px - p^2$, and $y = \dfrac{p}{a}x - \dfrac{p^2}{a}$. Compare this with equation (1), and it will appear that $\mathrm{P} = \dfrac{p}{a}$, $\mathrm{Q} = -\dfrac{p^2}{a}$; therefore $\dfrac{d\mathrm{P}}{dp} = \dfrac{1}{a}$; $\dfrac{d\mathrm{Q}}{dp} = -\dfrac{2p}{a}$; hence the nature of the curve is expressed by the two equations

$$y = \frac{p}{a}x - \frac{p^2}{a};\ \ 0 = \frac{1}{a}x - \frac{2p}{a}.$$

The second of these equations gives $p = \frac{1}{2}x$; and hence the first becomes $y = \dfrac{x^2}{2a} - \dfrac{x^2}{4a}$; therefore $4\,ay = x^2$ is the equation of the curve, which is evidently a parabola, of which AK is the axis, K the focus, and A the vertex.

Ex. 2. Suppose a ray of light RD, coming from the sun, to fall upon FEG, the concave surface of a sphere, at D, and to be thence reflected in the direction DH; it is proposed to find the nature of the curve to which this, and all rays reflected in the same manner, are tangents.

Fig. 34.



Draw AD the radius of the sphere, and AE parallel to the incident ray RD; let C be the point in which the reflected ray touches the curve; let DC meet AE in H, and draw CB perpendicular to AE. Put $\mathrm{AD} = a$, $\mathrm{AB} = x$, $\mathrm{BC} = y$, and let p be the variable angle DAE.

By the principles of optics, AD bisects the angle RDH, which is equal to DHE, that is, to the sum of the angles DAH, ADH; therefore the angles ADH, DAH are equal, and angle $\mathrm{DHE} = 2p$. Now, by trigonometry,

$$\mathrm{AH} = \frac{\sin \mathrm{ADH}}{\sin \mathrm{AHD}} \times \mathrm{AD} = \frac{\sin p}{\sin 2p}a,$$

$$\mathrm{BH} = \frac{\cos \mathrm{CHB}}{\sin \mathrm{CHB}} \times \mathrm{CB} = \frac{\cos 2p}{\sin 2p}y;$$

Hence $x = (\mathrm{AH} + \mathrm{BH}) = \dfrac{\sin p}{\sin 2p}a + \dfrac{\cos 2p}{\sin 2p}y,$

and $y = \dfrac{\sin 2p}{\cos 2p}x - \dfrac{\sin p}{\cos 2p}a \text{........................} (\alpha)$

By comparing this with the general formula (1), it appears that

$$\mathrm{P} = \frac{\sin 2p}{\cos 2p},\ \mathrm{Q} = -\frac{\sin p}{\cos 2p}a;\ \text{hence,}$$

$$\frac{d\mathrm{P}}{dp} = \frac{2}{\cos^2 2p},\ \frac{d\mathrm{Q}}{dp} = -\frac{\cos p}{\cos 2p}a - \frac{2\sin 2p \sin p}{\cos^2 2p}a.$$

Hence, by formula (2),

$$\frac{2x}{\cos^2 2p} = \left\{\frac{\cos p}{\cos 2p} + \frac{2\sin 2p \sin p}{\cos^2 2p}\right\}a \text{............} (\beta)$$

From equations (α) and (β) we readily find

$$x = (\tfrac{1}{2}\cos 2p \cos p + \sin 2p \sin p)\,a,$$

$$y = (\tfrac{1}{2}\sin 2p \cos p - \cos 2p \sin p)\,a;$$

and hence, by observing that $\sin 2p = 2 \sin p \cos p$, and that $\cos 2p = 2\cos^2 p - 1 = 1 - 2\sin^2 p$ (*Arithmetic of Sines*, ALGEBRA), we have also

$$= \tfrac{1}{2}\cos p\,(1 + 2\sin^2 p)\,a;\ y = (\sin^3 p)a.$$

From these equations it is easy to eliminate the trigonometrical quantities $\cos p$ and $\sin p$, and the result will be the equation of the curve, which is an epicycloid. The curve in question is the *catacaustic* curve to a circle.

It is easy to see that the general problem, of which we have now given two examples, is very comprehensive. We may evidently find, by the formulæ (1) and (2), *catacaustic* and *diacaustic* curves in all cases whatever. These, and an infinite number of other geometrical problems, are contained in the following more general problem.

Problem 3.

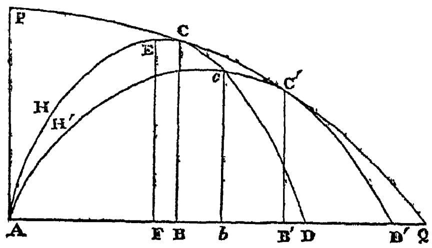
Determine the nature of a curve which touches an infinite number of lines of a given kind, described upon a plane according to some determinate law. For example, suppose the lines to be parabolas described by a projectile thrown from an engine with a given velocity, at every possible elevation in a vertical plane.

Let HCD be any one of the lines of a given kind (a parabola, for example), and suppose it referred to an axis AB, by the rectangular co-ordinates $\mathrm{AB} = x'$ and $\mathrm{BC} = y'$. Let p denote some quantity belonging to the line or curve HCD, which has always the same value in the same curve, but which has different values in different curves. Thus, if the curve be a circle, p may be its radius; or if the curve be a parabola, p may be its parameter, &c. This quantity p may also by analogy be called the *parameter* of the curve HCD. Let us suppose the nature of this curve to be expressed by the equation

$$f(x', y', p) = 0 \text{.........................} (1)$$

that is, let some function of x', y', and p, be supposed $= 0$. If p now be supposed to change its value, and become $p + h$, then the curve HCD will change its figure, and have some other position H′C′D′. Let $\mathrm{AB}' = x''$, and B′C′

Fig. 35.



Inverse Method.

$= y''$, be any co-ordinates of this other curve, and as, by hypothesis, the two curves are expressed by equations of the same form, we must have

$$f(x'', y'', p+h) = 0;$$

and this expression, by Taylor's theorem, is equivalent to
(2)

$$f(x'', y'', p) + \frac{d\{f(x'', y'', p)\}}{dp}h + \text{K}h^2 + \&c.,$$

the differential being taken upon the hypothesis that p alone is variable, and $\text{K}h^2$ + &c. being put for all terms of the series following the second, each of which is multiplied by a power of h.

Let the two curves intersect each other in c, and let $\text{A}b = x$, and $cb = y$, be the common co-ordinates; then, as equation (1) holds true of every point in the curve HCD, and equation (2) holds true of every point in H′C′D′, both must hold true at once, if we substitute in them x and y, the co-ordinates belonging to their common point c; that is, we must have

$$f(x, y, p) = 0,$$

$$f(x, y, p) + \frac{d\{f(x, y, p)\}}{dp}h + \text{K}h^2 + \&c. = 0;$$

and hence we must also have

$$\frac{d\{f(x, y, p)\}}{dp} + \text{K}h + \&c. = 0.$$

Let C and C′ be now supposed the points in which the curves HcD, H′cD′ touch the curve PCC′Q, whose nature is required; then, if we suppose h to decrease continually, and at last to vanish, the points C′ and c will approach to C, and at last will coincide with it, so that x and y, which are co-ordinates of c, the intersection of the two curves HcD, H′cD′, will then become the co-ordinates of the curve PCQ. As all the terms which contain h will then vanish, we have evidently this rule.

Let the equation of the given curves be

$$f(x, y, p) = 0\ldots\ldots\ldots\ldots\ldots(\alpha)$$

x and y being the co-ordinates, and p a variable parameter. From this equation, by taking the differential, supposing p to be variable, and all the other quantities constant, we deduce this other equation,

$$\frac{d\{f(x, y, p)\}}{dp} = 0\ldots\ldots\ldots(\beta)$$

By these eliminate p, and the result will be an equation, which expresses the nature of the curve that touches all the given curves.

Ex. Let ACD, AC′D′, &c. be parabolas described by a projectile thrown from a given point A, with a given velocity, in a given vertical plane. It is proposed to find the curve PCQ which touches them all. Let EF be the axis of any one of the curves, AD an ordinate to the axis, $\text{AP} = a$ the height due to the velocity of projection, $\text{AB} = x$, $\text{BC} = y$, the co-ordinates of C, any point in the curve. Put the parameter of the axis $= p$, and considering AD as a function of p, which is to be regarded as variable, put $\text{AD} = q$.

By the theory of projectiles, $\text{EF} = a - \frac{1}{4}p$, and by the nature of the parabola, $\text{AF}^2 = p \times \text{EF}$, and $\text{AB} \times \text{BD} = p \times \text{BC}$; hence we have these two equations,

$$qx - x^2 = py, \ (1) \qquad q^2 = 4ap - p^2, \ (2)$$

From the first of these,

$$f(x, y, p) = x^2 + py - qx = 0;$$

and, taking the differentials, considering x and y as constant, and q as a function of the variable quantity p,

$$\frac{d\{f(x, y, p)\}}{dp} = y - \frac{dq}{dp}x = 0,$$

therefore $\frac{y}{x} = \frac{dq}{dp}$; but from equation (2), taking the differentials, $qdq = 2adp - pdp$, and hence $\frac{dq}{dp} = \frac{2a - p}{q}$, and by the first equation $\frac{y}{x} = \frac{q - x}{p}$, therefore $\frac{q - x}{p} = \frac{2a - p}{q}$, and hence $q^2 - qx = 2ap - p^2$; and substituting for q^2 its value given by equation (2), we get $qx = 2ap$; hence, and by equation (1),

$$p = \frac{x^2}{2a - y}, \qquad q = \frac{2ax}{2a - y}.$$

These values of p and q being substituted in the second equation, and the common denominator rejected, it becomes

$$4a^2x^2 = (8a^2 - 4ay - x^2)x^2.$$

Hence $4\,ay = 4\,a^2 - x^2$, and this is the equation of the curve PCQ, which is evidently a parabola having its focus at A, the common intersection of all the parabolas, its axis perpendicular to the horizon, and its parameter $= 4\,a$.

The geometrical theory comprehended in the second and third problems has a corresponding analytical theory relating to the integrals of certain differential equations. This is the theory of *singular* primitive equations, which are not included in the *complete* primitive equation. Thus, the differential equation

$$dy \sqrt{(x^2 + y^2 - b)} - ydx - xdx = 0,$$

has for its complete primitive equation

$$x^2 - 2ay - a^2 - b = 0,$$

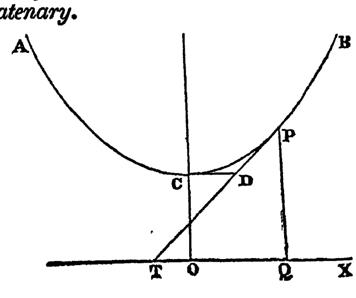
where a is the arbitrary constant quantity; but, besides this, it has a *singular* primitive equation,

$$x^2 + y^2 - b = 0,$$

which does not admit of an arbitrary constant, although it equally satisfies the differential equation, as is easily proved by differentiating. The bounds within which it was proper to confine this treatise have not allowed us to enter into this branch of the subject, which, although interesting, is yet not elementary.

Investigation of the Properties of the Catenary.

Suppose a chain or thread of uniform thickness, and perfectly flexible, but inextensible, to be fastened by its extremities at two points A, B in a vertical plane; by the action of gravity it will take the form of a curve ACPB, called the *catenary*.



The curve will evidently be all in one plane, and a horizontal line CD, in that plane, at C its lowest point, will manifestly touch the curve, which is retained at rest by a mutual balancing of the forces produced by the weight of the particles of the chain.

If we suppose its lowest point to be fixed at C, it is easy to understand that the part BC will not on that account change in the least its figure, because the tension of the chain at C, when it was free, is now replaced by the reaction of the force exerted in the horizontal direction CD.

Inverse Method.

The forces exerted on the points B, C will evidently be the same in quantity and in direction, whether the chain be considered as flexible, or rigid like a solid wire; hence it may be regarded as kept at rest by three forces, viz. its gravity acting vertically, and the re-actions of the tensions at B and C; the former exerted in the direction of a tangent to the curve at B, and the latter in the direction CD, the tangent at the lowest point C.

In like manner any portion PC between P and its lowest point may be considered as kept at rest by the joint action of the gravity of the mass PC, the tension of the chain at C, which is constant, and the tension at P, which is variable; and by the nature of an equilibrium (MECHANICS), these forces will be to each other as the sides of any triangle which are parallel to their directions. Draw a horizontal line OX in the plane of the curve as an axis, meeting the vertical through C in O, which may be taken as an origin of co-ordinates; draw PQ perpendicular to OX, and PT touching the curve and meeting the axis in T. From what has been explained, the tension of the curve at C will be to the weight of the matter in PC as TQ to PQ, that is, as radius to the tangent of the angle which PT makes with any horizontal line.

Put $OQ = x$, $PQ = y$, arc $CP = z$, angle $PTQ = \varphi$; and let a be the tension of the curve at the vertex C: we have then $a : z = 1 : \tan \varphi$; hence

$$\tan \varphi = \frac{z}{a} \quad \text{.........................(1)}$$

This is the distinguishing property of the curve, from which we are to deduce its other properties.

From equation (1), by differentiation,

$$\frac{d\varphi}{\cos^2 \varphi} = \frac{dz}{a}.$$

Now in all curves,

$$dz = \frac{dx}{\cos \varphi} = \frac{dy}{\sin \varphi};$$

hence we obtain

$$dx = a \,.\, \frac{d\varphi}{\cos \varphi}, \quad dy = a \,.\, \frac{d\varphi \sin \varphi}{\cos \varphi}.$$

From these, by integration,

$$x = a \,\text{l.} \tan (45^\circ + \tfrac{1}{2}\varphi) + \text{const. (art. 155)}$$

$$y = \frac{a}{\cos \varphi} + \text{const.}$$

If we assume that OC measures the tension at C, which is a constant quantity, then because when $\varphi = 0$, $x = 0$, and $y = a$, we have the relation of the quantities x, y, φ, expressed by these equations,

$$\left. \begin{aligned} x &= a \,\text{l.} \tan (45^\circ + \tfrac{1}{2}\varphi), \\ y &= \frac{a}{\cos \varphi} = a \sec \varphi. \end{aligned} \right\} \quad \text{.....................(2)}$$

The constant line a is called the *parameter* of the curve, also its *modulus*. From the first of these equations, putting ψ for $45^\circ + \tfrac{1}{2}\varphi$, we have

$$\tan \psi = e^{\frac{x}{a}}, \; \cot \psi = e^{\frac{-x}{a}},$$

$$\tan \psi + \cot \psi = e^{\frac{x}{a}} + e^{\frac{-x}{a}}.$$

Now,
$$\tan \psi + \cot \psi = \frac{\sin \psi}{\cos \psi} + \frac{\cos \psi}{\sin \psi},$$

$$= \frac{2}{\sin 2\psi} = \frac{2}{\cos \varphi} = \frac{2y}{a};$$

therefore
$$y = \frac{a}{2}\left\{ e^{\frac{x}{a}} + e^{\frac{-x}{a}} \right\} \quad \text{........................(3)}$$

This exponential equation expresses the relation between x and y by means of e, the base of Napier's logarithms. From this last equation, observing that $y = a \sec \varphi$, we get

$$\sec^2 \varphi = \tfrac{1}{4}\left\{ e^{\frac{2x}{a}} + e^{\frac{-2x}{a}} + 2 \right\},$$

$$\sec^2 \varphi - 1 = \tfrac{1}{4}\left\{ e^{\frac{2x}{a}} + e^{\frac{-2x}{a}} - 2 \right\},$$

$$\tan \varphi = \sqrt{\sec^2 \varphi - 1} = \tfrac{1}{2}\left\{ e^{\frac{x}{a}} - e^{\frac{-x}{a}} \right\}.$$

But it was found that $z = a \tan \varphi$,

therefore
$$z = \frac{a}{2}\left\{ e^{\frac{x}{a}} - e^{\frac{-x}{a}} \right\} \quad \text{..................(4)}$$

From formulæ (3) and (4) we have

$$y + z = ae^{\frac{x}{a}}, \quad y - z = ae^{\frac{-x}{a}} \quad \text{............(5)}$$

therefore $y^2 - z^2 = a^2$ ....(6)

hence again,

$$y = \sqrt{a^2 + z^2}, \; z = \sqrt{y^2 - a^2} \quad \text{....................(7)}$$

and since from formula (5)

$$\frac{x}{a} = \text{l.} \frac{y + z}{a} = \text{l.} \frac{a}{y - z} \quad \text{..........................(8)}$$

therefore also,
$$\frac{x}{a} \left\{ \begin{aligned} &= \text{l.} \frac{y + \sqrt{y^2 - a^2}}{a} \\ &= \text{l.} \frac{z + \sqrt{z^2 + a^2}}{a} \end{aligned} \right\} \quad \text{..........(9)}$$

Let s denote the area bounded by the arc PC and the straight lines CO, OQ, PQ; then, since $dx = \frac{a d\varphi}{\cos \varphi}$, and $y = \frac{a}{\cos \varphi}$, therefore

$$ds = y dx = \frac{a^2 d\varphi}{\cos^2 \varphi} = a dz.$$

and $s = az$ ....(10)

Thus it appears that the arc CP is always proportional to the conterminous area CPQO. It is evident that the catenary, if inverted, would form an equilibrated arch. From this property it appears that if a wall, whose height above the crown of the arch is equal to the line CO, be horizontal at the top, the structure thus formed will constitute an equilibrated arch with a straight roadway. (See on this subject our article ARCH.) (W. W.)

FLY. See *Diptera*, index to ENTOMOLOGY.

FLY, in *Mechanics*, the name of an appendage to many machines, either as a regulator of their motions or as an accumulator of power. It is usually in the form of a metal disc, or a wheel with a heavy rim, sometimes in that of a cross or bar loaded at the extremities, and is attached to the revolving shaft of the machine in order to distribute the force of the power equally in all parts of its revolution. When used as an accumulator of power for the purpose of producing a very great instantaneous effect, as in the coining press, it is frequently seen in the form of heavy knobs at the opposite extremities of a straight bar. The fly is especially useful in all cases where the power or the resistance acts with an irregular or intermitting force in the different parts of a revolution.

FLY-CATCHER. See index to ORNITHOLOGY.

FLYING, the progressive motion of a bird or other winged animal through the air.

Artificial FLYING. Attempts have been made by various persons in all ages to imitate the motions of birds in the air by means of mechanical contrivances, but hitherto with very little success—the balloon being the only known machine that can sustain the body of a man in the air for any considerable length of time. Friar Bacon tells us that he knew how to make a machine by which a man might convey himself through the air like a bird; and he adds, that a person had tried it with success. The secret consisted in a couple of large thin hollow copper globes, exhausted of air; which being much lighter than common air, would sustain a chair on which a person might sit and be buoyed along. Father Francisco Lana, in his *Prodromo*, proposes the same thing. He computes that a round vessel of plate-brass, fourteen feet in diameter, weighing three ounces the square foot, will only weigh 1848 ounces, whereas a quantity of air of the same bulk will weigh 2155$\frac{2}{3}$ ounces, so that the globe will not only be sustained in the air, but will carry with it a weight of 307$\frac{2}{3}$ ounces; and by increasing the bulk of the globe without increasing the thickness of the metal, he conceives that a vessel might be made to carry a much greater weight. But the fallacy is obvious. A globe of the dimensions he describes, as shown by Dr Hook, would not sustain the pressure of the air, but be crushed inwards. Besides, in whatever ratio the bulk of the globe is increased, in the same ratio must the thickness of the metal, and consequently the weight, be increased; so that there would be no advantage in such augmentation.

The philosophers of Charles II.'s time were much busied about this art. The celebrated Bishop Wilkins was so confident of success in the attempt, that he says he does not question but in future ages it will be as usual to hear a man call for his wings when he is going a journey as it is now to call for his boots. Among such contrivances may be noticed another, consisting of huge wings, the cavities of which are to be filled with hydrogen gas, and which the flying man is to move with his arms. It is almost needless to observe that this machine is quite incapable of effecting the object in view, as must be every other constructed upon the same principle.

The flying apparatus constructed by Sir George Cayley can scarcely be considered as a successful experiment, since the wings of that ingenious mechanician acted rather on the principle of the parachute, merely floating the experimenter, who started from a moderate elevation, by a very gradual descent towards the earth.

FLYING FISH, a name given to several species of fishes which, by means of long fins, can sustain themselves for some time in the air. The common flying fish of the Mediterranean is thus able to raise itself so far above the surface of the sea as frequently to throw itself upon the deck of a ship; but the extreme limit of its flight is confined to an arch extending about 120 feet, when the drying of its fins necessitates its return to its proper element. See index to ICHTHYOLOGY.

FOAL, the young of the horse kind. The word *colt*, among dealers, is applied to the male, and *filly* to the female.

FOCHABERS, a village of Scotland, parish of Bellie, Morayshire, situated on the Spey, 4 miles from its mouth in the Moray Firth, and 9 miles E. of Elgin. It is neatly built; and in the vicinity is the magnificent domain of Gordon Castle, the property of the Duke of Richmond.

FOCUS, in *Geometry* and *Conic Sections*, is applied to a certain point in the parabola, ellipsis, and hyperbola, where the rays reflected from all parts of these curves meet. In *Optics*, a point in which any number of rays meet, after being reflected or refracted.

FŒTUS, the young of viviparous animals whilst in the womb, and of oviparous animals before being hatched. See ANATOMY, and PHYSIOLOGY.

FOG, or MIST See METEOROLOGY, and PHYSICAL GEOGRAPHY.

FOGGIA, a city of Naples, capital of the province of Capitanata, and situated near the centre of the great plain of Apulia, 80 miles E.N.E. of Naples. The town is well built; and the principal streets, which are wide and clean, contain some handsome houses and good shops. The cathedral, originally a stately Gothic edifice, was destroyed by an earthquake in 1731, and the upper part of it has been rebuilt in a different style, by which its effect is greatly injured. Foggia contains numerous other churches, a governor's palace, theatre, custom-house, and the remains of a palace which, together with a large well, was constructed by Frederick II. It is the seat of the provincial courts, and the centre of all the trade of the province, which, in spite of its ill-chosen and unhealthy situation, give it a more animated appearance than any other city in the kingdom except the capital. The corn magazines (fosse) are very extensive, consisting of vaults lined with masonry, extending under the principal streets and squares. Foggia is a staple market for corn and wool, and the place at which a toll is collected upon the numerous flocks of sheep that descend annually in autumn from the mountains of Abruzzo into the plains of Apulia, to avoid the cold of the high country. It is traversed by roads leading to Naples, Bari, Piscara, Bovino, Manfredonia, &c., and is thus the entrepôt of an extensive trade in agricultural and other produce. Pop. about 21,000.

FOGO, one of the Cape Verd Islands, lying W. of Santiago, in N. Lat. 14. 50., W. Long. 24. 34. It is about 40 miles in circumference, and is almost entirely occupied by a volcanic mountain, which rises to the height of upwards of 9000 feet. An eruption of this volcano took place in 1847, and caused great damage. The island is very fertile, and contains about 7000 inhabitants.

FOHR or FORA, an island of Denmark, lying off the coast of Schleswig, in the North Sea; N. Lat. 54. 43., E. Long. 8. 30.; area 25 square miles. The eastern part of the island, with a population of 2650, belongs to Schleswig; and the western, with 2100 inhabitants, to Jutland. The inhabitants are chiefly engaged in navigation, fishery, manufacture of hosiery, and the taking of wild fowl. The principal port is Wyk.

FOIL, in fencing, a kind of blunt sword, which is tipped with a button covered with leather.

FOIL, among jewellers, a thin leaf of metal placed under transparent stones in order to improve their colour or heighten their lustre. Foil also denotes the sheet of tin amalgam laid on the back of a mirror to make it reflect a perfect image. Coloured foils are prepared by covering thin sheets of copper, highly polished, with coloured varnishes.

FOIX, a town of France, capital of a cognominal arron-

dissement, and also of the department of Ariège, is situated on the left bank of the Ariège, in the gorge of a narrow valley, bounded by rocky and precipitous hills, 44 miles S. of Toulouse. It was the capital of the old Comté de Foix; and on an isolated rock, rising from amidst the houses, stands the old castle of the counts. It has three fine towers, all anterior to the fifteenth century, the tallest being 136 feet high. They are now used as a prison. Foix has a considerable trade in iron. Pop. (1851) 4110.

FO-KIEN, or FU-KIANI, a large province of China, bounded on the N. by Che-Kiang, E. by the Chinese Sea, S. by Kwang-Tung, and W. by Kiang-Si: estimated area, 53,480 square miles. This province is generally mountainous, particularly in the northern and western parts, where it is bounded by the high range of the Nanling. Its sea-coast is bold and rugged, but presents many capacious and secure harbours. Off the coast lie numerous islands, whose lofty granitic or trap peaks extend in precipitous barren headlands from Namoh as far as the Chusan Archipelago. The river Min, formed by the union of three large streams at Yenping-fu, drains about three-fourths of the province, or all that part of it lying east of the Wu-i hills, and empties itself into the ocean by several mouths. Tea, sugar, camphor, tobacco, and indigo are the chief articles grown for export. The population is estimated at 15,000,000.

FOKSCHAN, or FOKSCHANI, a town of European Turkey, on the Milkov, 92 miles N.N.E. of Bucharest. It consists of two parts, one of which belongs to Wallachia, the other to Moldavia; and has a considerable trade in cattle, corn, and other agricultural produce. Good wine is produced in the vicinity. Pop. 6000.

FOLARD, JEAN CHARLES DE, born on the 13th of February 1669 at Avignon, was a French military officer distinguished for his writings on tactics. His genius was roused by reading Cæsar's *Commentaries;* and at the age of sixteen he entered the army contrary to his father's wish. By the Duke of Vendôme, who commanded in Italy in 1702, he was intrusted with part of his forces; and so well did he acquit himself, that he was honoured with the cross of St Louis, and received a pension of 400 livres. In the battle of Cassano, in August 1705, he lost, by a wound, the use of his left hand; and in 1706 he defended Modena against Prince Eugene, by whom he was taken prisoner some time after the battle of Blenheim. In 1711 he was appointed governor of Bourbourg, and in 1714 helped to defend Malta against the Turks. Soon after this he entered the service of Charles XII. of Sweden, and accompanied him in the invasion of Norway; but returned to France, where he served as colonel under the Duke of Berwick. In his later years he applied himself to the study of military art, and died at Avignon in 1752. His works are: *Nouvelles Découvertes sur la Guerre*, 1724, 12mo; *Commentaires sur Polybe*, 1753, 7 vols. 4to; and *Fonctions et Devoirs d'un Officier de Cavalerie*, 1733, 12mo.

FOLCLANDS, or FOLKLANDS. Copyhold lands were so called in the time of the Saxons, as charter-lands were called *boclands*. *Fockland* was *terra vulgi* or *terra popularis*, the land of the common people, who had no certain estate therein, but held it under the rents and services accustomed or agreed, at the will only of their lord the thane; and it was therefore not put in writing, but accounted *prædium rusticum et ignobile*.

FOLCMOTE, or FOLKMOTE (Saxon, *folcgemote*, that is, *conventus populi*), is composed of *folk*, people, and *mote* or *gemote*, to assemble, and originally signified a convention of the people, to consult respecting public affairs. According to Spelman, the *folcmote* was a sort of annual parliament or convention of the bishops, thanes, aldermen, and freemen, which assembled upon every May-day, and in which the laymen were sworn to defend one another and the king, and to preserve the laws of the kingdom, after which they consulted of the common safety. But, from the laws of the Saxon kings of England, Dr Brady infers that it was an inferior court, held before the king's *reeve* or steward every month, to do *folk* right, or compose smaller differences; and that from it there lay an appeal to the superior courts. Squire seems to think that the *folkmote* was not essentially distinct from the *shiremote*, or common general meeting of the county. (See his *Angl. Sax. Gov.* 155, n.) Manwood mentions *folcmote* as a court holden in London, in which all the *folk* and people of the city did complain of the mayor and aldermen for misgovernment within the said city; and this word is still in use, denoting *celebrem ex tota civitate conventum.* According to Kennet, the *folkmote* was a common council of all the inhabitants of a city, town, or borough, convened by sound of bell, or otherwise, to the *Mote Hall* or *House;* or it was applied to a larger congress of the freemen within a county, called the *shiremote*, where formerly all knights and military tenants did homage to the king, and elected the annual sheriff on the first of October, until 1315, when, to avoid tumults and riots, this popular form of election was by 3d Edward I. merged in nomination by the king. After this time the city *folkmote* was swallowed up in a select committee or common council and the county *folkmote* in the sheriff's tourn and assizes.

The word *folkmote* was also used to signify any kind of popular or public meetings, as those of the tenants at the *court leet* or *court baron*, in which signification it was of a less extent than that above explained. (*Paroch Antiq.* 120.)

FOLDVAR, a town of Hungary, county of Tolna, on the right bank of the Danube, 50 miles S. of Buda. It is a steam-packet station, but is chiefly noted for its sturgeon-fishery. Pop. 10,000.

FOLENGO, THEOPHILUS, better known by his assumed name of *Merlin Cocajo*, an eccentric genius and burlesque poet, was descended of a noble family of Mantua, and born at a place called Cipada in the year 1491.[1] From his infancy he showed great vivacity of mind, and a singular facility of turning everything that occurred into verse. He completed his studies at Bologna, and at the age of sixteen entered the order of Benedictines of the congregation of Monte Cassino, near Brescia. He then assumed the name of Theophilus instead of Jerome, which was his baptismal name, and eighteen months afterwards he made profession as Benedictine. At first his life was regular; but he soon forgot his vows, and ended by quitting the monastery to stroll about with a young woman named Giron Dieda, who had captivated his fancy. With her he wandered about for ten years, with no other resource for procuring a livelihood than his talents and his verses. He had commenced a poem in Latin, which, as far as it went, displayed much elegance; but he soon quitted serious poetry, in which he could at most only hope to obtain a secondary rank, for a kind which he called Macaronic, in which he conceived himself qualified to occupy the first place. The basis of the language employed by him is Latin, mixed with Italian words, and still more with the Mantuan patois, which was his mother tongue, and to which he gave Latin terminations. In his

[1] Folengo, in his verses, has several times mentioned the place of his birth in his own peculiar vein:

Magna suo veniat Merlino parva Cipada.—
Mantua Virgilio gaudet, Verona Catullo,
Dante suo florens urbs Tusca, Cipada Cocajo.—
Nec Merlinus ego, laus, gloria, fama Cipadæ, etc.

poem he recounts the ridiculous adventures of a hero called Baldus, among which are several which had happened to himself; and under the mask of burlesque and buffoonery may be found thoughts and maxims instinct with good sense, not to mention original and piquant touches of satire on the conduct of the great, the vanity of titles, and the different pursuits of men. Instead of dividing his poem into books or cantos, he divided it into macaronis (*macaronea prima*, *macaronea secunda*, etc.), of which there were seventeen in the first edition and twenty-five in the subsequent ones; and he published the whole under the name of *Merlinus Cocajus*, which afterwards became famous. In a few years several editions were published; but the success of these facetious productions did not prevent their being bitterly criticised. The author was severely censured, both for the style and the license of idea and expression in which he indulged; a circumstance which irritated him so much that, changing language and name, he composed in three months a satirical Italian poem, in eight cantos, on the infancy of Roland, to which he gave the title of *Orlandino*, and affixed the name of *Limerno Pitocco; Limerno* being the anagram of *Merlino*, and *Pitocco* or *mendicant* being significative of the state to which he was occasionally reduced. He had nevertheless made many friends in the world by the reputation which he had acquired, the extent of his knowledge, and the agreeable qualities of his mind; and he had even retained some in the cloister, into which, when tired of a wandering and miserable life, he was received back with open arms. He signalized his return by a work on the subject of his conversion, entitled *Il Chaos del Triperuno*, or The Chaos of Three for One, meaning himself, who had been successively Theophilus Folengo, Merlin Cocajo, and Limerno Pitocco. The work is a medley of verses, songs, and narrations, in Latin, Italian, and the Macaronic dialect, in short, a veritable chaos, divided into three parts, called, after Statius, *Sylvæ*. Folengo appears to have remained during several years at Capri, a country house belonging to his order, between Brescia and Bergamo, and to have divided his time between this retreat and Brescia till 1536 or 1537, in one or other of which years he composed his Italian poem on the Humanity of the Son of God, the most orthodox of all his works, and which would be the most edifying if one could really be edified by that which is unreadable. He was then sent into Sicily to the monastery of St Martin delle Scale, where he appears to have remained till 1543, when he returned into Italy, and retired to the convent of the Holy Cross of Campesa, near Bassano, on the banks of the Brenta, where he died in little more than a year afterwards, 9th December 1544, in the fifty-third year of his age.

FOLIATING OF LOOKING-GLASSES, the process of covering the glass with amalgam, in order that it may reflect the image. The method, as practised at the largest looking-glass manufactory in Britain, at St Helen's in Lancashire, is as follows:—On a smooth and level table of stone or iron with a slightly elevated border, mercury is poured in a thin stratum: the mercury is covered with tinfoil; and the glass-plate, previously well cleaned, is slowly slid along the metallic surface, so as to exclude air-bubbles: weights are then placed on the glass, to make its contact with the amalgam of tin and mercury more complete. The amalgam soon adheres to the plate, which is then raised on its edge to allow the superfluous mercury to drain off. It is then carried to the *drying-room*—and the process is complete.

FOLIGNO, the ancient *Fulginium*, a town of the Papal States, delegation of Perugia, on the Topino, 20 miles S.E. of Perugia. This is an active and industrious town, and has manufactures of woollens, paper, parchment, and wax candles. It has a cathedral and numerous churches, some of which contain fine paintings. During the middle ages it for a long time maintained its independence, but was at length reduced by its more powerful neighbours; and in 1439 was incorporated with the States of the Church. Pop. 9000.

FOLIO, a book of the largest size, formed by once doubling a sheet of paper. It is also applied to the opposite pages of an account-book, expressed by the same figure.

FOLKES, MARTIN, an eminent English antiquary, was born at London in 1690. At the age of seventeen he was entered of Clarehall, Cambridge, where he distinguished himself so much in mathematics, that when only twenty-three years of age he was chosen a fellow of the Royal Society. Newton, the president of that body, secured his election as one of the vice-presidents; and on the death of that great philosopher, Folkes became a candidate for the presidency, but without success, as the higher standing and superior influence of Sir Hans Sloane carried the election against him. In 1733 he set out on a tour through Italy, in the course of which he composed his admirable "Dissertations on the Weights and Values of Ancient Coins," which he read before the Society of Antiquaries. Before that same body he read in 1736 his "Observations on the Trajan and Antonine Pillars at Rome," a work which was afterwards printed. In that same year he communicated to this same society his "Table of English Gold Coins from the 18th year of King Edward III., when gold was first coined in England, to the present time, with their Weights and Intrinsic Values;" and in 1745 he printed this work along with another on the history of silver coinage. In 1741 Folkes succeeded Sir Hans Sloane as president of the Royal Society; in the following year he was made a member of the French Academy; and 1746 was honoured with the degree of LL.D. from Cambridge and Oxford. He died in 1754.

FOLKESTONE, or FOLKSTONE, a municipal borough, seaport, and market-town of England, county of Kent, 7 miles W.S.W. of Dover, of which it is a sub-port. It is governed by a mayor, 4 aldermen, and 12 councillors, and is included in the parliamentary borough of Hythe. At an early period this was a place of some importance, and since the opening of the South-Eastern Railway it has been rapidly increasing. It is situated in a hollow between two precipitous chalk cliffs, and is irregularly built. The parish church is a cruciform structure in the early Gothic style, with a tower rising from the intersection. There are several Dissenting chapels, a grammar-school, market-house, and baths. It is frequented in summer for sea-bathing; and many of the inhabitants are engaged in the fisheries. The coast is defended by three martello towers; and a strong modern battery, situated on the heights, protects the town. The pier-harbour is 19 acres in extent, and has recently been much improved by the removal of shingle at its mouth, so as now to admit vessels of 150 tons burden. The South-Eastern Railway is here conducted over a magnificent viaduct; and steam-packets ply daily between this town and Boulogne. On 31st December 1853, 14 vessels of 1037 tons were registered as belonging to the port, and during that year 305 sailing vessels of 30,350 tons, and 431 steam vessels of 64,781 tons, entered; and 9 sailing vessels of 719 tons, and 429 steam vessels of 64,638 tons, cleared at the port. In 1847 the custom-house receipts amounted to only L.4008, and in 1852 had increased to L.122,133. This town has suffered much at different periods from encroachments of the sea. Harvey, the discoverer of the circulation of the blood, was born here in 1578. Market-day, Thursday. Pop. (1851) 6726.

FOLLICLE (*follis*, a bag), in *Botany*, a carpel that opens longitudinally by the ventral suture, and of which the pericarp is not fleshy, but usually foliaceous. There are generally many follicles in the same flower. It is also applied to a vessel distended with air; as on the leaves of aldrovanda.—In animal bodies, a gland, folding, or cavity.

FOMALHAUT, a star of the first magnitude, in the constellation PISCIS AUSTRALIS; rt. ascen. (1856) 22:49:41: decl. 30:23:3·7, with annual var. = + 3·33 seconds.

FONDI, the ancient *Fundi*, a town of Naples, province of Terra di Lavoro, 14 miles N.W. of Gaëta. This is now a wretched town of about 5000 inhabitants, and only remarkable for the remains of the ancient city. The Appian Way passes through the town, and constitutes its principal street, the ancient pavement being still almost entire. Remains of the cyclopean walls, and of numerous ancient buildings, are still to be seen. The cathedral is a very ancient Gothic edifice. Fundi was celebrated among the Romans for the excellence of its wines, and the famous *Cæcubus Ager* was in the vicinity. The town is very unhealthy from proximity to the *Lacus Fundanus*.

FONT (*fons*), a vessel used in churches to hold water for the purpose of baptism, and also for holy water in Roman Catholic churches. Many of the English fonts are curious both for their antiquity and their elaborate architectural embellishments.

Font or Fount (*fondre*, to cast), in *Printing*, a complete assortment of printing types of one size, including the running letters, large and small capitals, points, numeral characters, &c. See Type-Founding, and Printing.

FONTAINE, Jean de La, the celebrated French fabulist, and one of the greatest of French poets, was born in 1621 at Château-Thierry in Champagne. His father was Maître des Eaux et des Forêts in that town, and had little time to bestow on the education of his son, who did not exhibit a spark of intelligence till he had reached his twenty-second year. At Rheims, where he got all the education he ever received, he devoted himself more to pleasure than to study, and in after days described in flowing and melodious verse the gallantries of which he had then been guilty. In 1641 he entered the monastery of the Oratoire, but finding the monkish way of life extremely distasteful, he left it and returned home. Soon after this he married and succeeded his father in his office, performed his duties extremely ill, and finally abandoned his wife (with whom he had lived on very indifferent terms) to go to Paris in the train of the Duchess de Bouillon, niece of Cardinal Mazarin. Before this time, however, his mind had begun to awaken to a consciousness of its strength. An ode of Malherbe, which was once read in his hearing, is said to have elicited from him the expression, "I too am a poet," and to have first stimulated him to literary enterprise. He began a systematic study of the writers of his own country and of the ancient classics, and the first-fruits of his labours was a translation of the "*Eunuchus*" of Terence. This work had very poor success, and was in many respects so unsatisfactory as not to deserve much. In the French metropolis La Fontaine was kindly received, and spent much of his time and far more money than he could afford in the pursuit of those pleasures for which that city affords unrivalled facilities; but none of the reverses of fortune by which he was overtaken ever altered his disposition in the least. His indifference to his worldly affairs compelled him to sell year by year a portion of his patrimonial estate, and it is not known to what straits he might have been reduced had not a charitable lady, Mme. de la Sablière, received him into her house, and taken care of him for twenty years. When driven by her own necessities to reduce her establishment, this lady used to talk to her friends of having retained only her three animals—her dog, her cat, and La Fontaine. In 1684 La Fontaine was admitted into the French Academy, but Louis XIV., indignant that he should have been preferred to Boileau, refused to sanction his appointment. Another vacancy occurring soon after gave an opportunity for Boileau's election, and both candidates were admitted without any opposition from the king. On the death of Mme. de la Sablière, La Fontaine was reduced to great extremities, and had seriously bethought himself of going to England on the invitation of St Evremond. Luckily, the kind intervention of the Duke of Burgundy in his behalf enabled him to remain at home. His health at this time became very bad, and was not much improved by his squabbles with the clergy, who, believing him to be dying, threatened him with the terrors of the church unless he made a public apology for his licentious tales, and burned a comedy which he was preparing for the stage. After a good deal of hesitation, he complied with both these demands. In 1693 his health became rapidly worse, and he spent the most of his time in translating hymns for the church and in other literary exercises, chiefly of a religious character. His last days were cared for by the kindness of his friend D'Hervart, who received him into his house and tended him with almost filial care till his death in 1695.

The character of La Fontaine is a curious medley of strength and weakness. His acute perception of what was right, and his inability to practise it, remind us of Richard Steele. His invincible laziness and good-humour are only to be paralleled by the similar qualities in the author of *The Seasons*. His shrewd yet childlike simplicity, his vanity, his tenderness of heart, his awkwardness, and his absence of mind, are all qualities which he had in common with our own Goldsmith; and indeed, the epithet of "inspired idiot," unjustly applied to that author, might with much propriety have been given to the French fabulist. His weaknesses were all of a kind that made him at once the pet and the laughing-stock of his friends. With Racine, Molière, and Boileau he lived on terms of the most intimate friendship. They often rallied him, and sometimes with good reason, on his many failings; but as Molière said on one of these occasions, "Ils ont beau se trémousser, ils n'effaceront pas le bonhomme." The sobriquet of "Le Bonhomme" was so pat that it stuck to him through life, and has been confirmed by posterity. He often exhibited the strangest want of interest in matters of the deepest concern, and a dreamy absorption in trifles, such as seemed to argue some unaccountable intellectual weakness. Possessed as he undoubtedly was of rare and remarkable literary powers, his range both of sympathy and knowledge in literary affairs was astonishingly limited. On one occasion hearing Racine read some extracts from Plato, he suddenly broke out into a rhapsody of admiration for the Greek philosopher, whom he praised as one of the most amusing of writers. At another time, being present at a theological debate that was carried on with much spirit, he fell asleep, and on awakening asked the company whether they thought that St Augustine was as witty a writer as Rabelais. Racine once took him to the "Tenebræ," and seeing that he was wearied by the length of the performance, put a Bible into his hands. La Fontaine opened it at the book of Baruch, and was so much struck with what he there read that he could not help crying out to his companion, "This Baruch is a very fine writer; do you know anything of him?" And for several days after he asked everybody that he met, "Have you ever read Baruch? He's a man of first-rate genius. Do you know who he was?" One day he met his own son, whom he did not recognise, and remarked to him that he was a lad of parts and spirit. Being told that the youth was his own son, he merely observed that "he was very glad to hear it." In 1693, when he was believed to be dying, Poujet, vicar of St Roch, brought him the New Testament. He read it, and assured his friends "Je vous assure que c'est un fort bon livre; oui, par ma foi, c'est un fort bon livre."

As an author, La Fontaine will be best known to posterity by his Fables. He published other works, of which the best known are his "*Contes*" or Tales, the first volume of which appeared in 1664, the second in 1671. These abound in fine touches of his genius, but are polluted with such a taint of gross license and indecency that they are now seldom read even by his own countrymen. As a

fabulist, however, La Fontaine has never had his equal either in ancient or modern times. He has, indeed, little or no originality of invention, for most of his tales are taken from Boccaccio, Ariosto, Machiavelli, and others; and Æsop has suggested the idea of the great majority of his fables. His reflections are not remarkable either for depth or novelty, and he displays an almost total incapacity for continuous thinking; but his manner of telling his stories is quite inimitable, and in that lies the principal charm of his writings. 'His narrative,' as has been remarked by Laharpe, 'is distinguished by that ease and grace which are to be perceived, not described; for if after a profound philosophical investigation we arrived at the ultimate causes of excellence, and referred the matter to La Fontaine himself, the 'bonhomme' would say "I know nothing about all this; I wrote as my humour dictated, and that was all."' The rapidity of his transitions from the most sparkling wit to the most touching pathos, his occasional gleams of the finest humour and fancy, and his delicate touches of observation, are all enhanced by a diction simple and refined, and presenting in almost every line some happy turn of expression, or some graceful naïveté of sentiment. (For a detailed analysis of La Fontaine's fables, see art. FABLE.)

There have been many editions of the *Fables*, of which the most sumptuous is that of 1755–59, in 4 vols. fol. La Fontaine's other works are *Les Amours de Psyché*, a romance; *Le Florentin*, a comedy; *L'Eunuque*, a translation from Terence; *Anacréontiques*, *Lettres*, and some pièces d'occasion, published collectively in *Les Œuvres diverses de La Fontaine.*

FONTAINEBLEAU, a town of France, capital of an arrondissement in the department of Seine-et-Marne, is distant about 37 miles in a S.E. direction from Paris, on the lines of high road and railway that connect that city with Lyons. Pop. of commune (1851) 8278. The town stands in the midst of the Forest of Fontainebleau (which is nearly 64 square miles in extent); is well-built, and has some wide and handsome streets. It possesses a college, excellent barracks for cavalry, hospitals of various kinds, public baths, and a good public library. In the immediate vicinity of the town is the celebrated palace—one of the largest, and interiorly one of the most sumptuous of the royal residences in France. The kings of France are known to have had a palace at Fontainebleau as far back as the year 1169; and this palace was a favourite abode of Louis VII., Philippe-Auguste, and St Louis. The existing building was begun by Francis I., who laid out immense sums of money upon it. Primaticcio, a famous Italian architect, was instructed to draw out the plans of it; while such artists as Leonardo da Vinci, Andrea del Sarto, and Benvenuto, were commissioned to expend upon it all the resources of their various arts to make the place a truly royal residence. The edifice was completed as it now stands by Louis XIV.; but after his death it fell into disfavour, and was used for a while as a military school. Napoleon restored it with great splendour, and often resided in it; but after the Restoration it was allowed to fall into disrepair. Louis-Philippe expended immense sums of money upon it; and in point of internal decoration it is now inferior to none of the French palaces.

Many events of importance have taken place at Fontainebleau. Philippe-le-Bel, Henri III., and Louis XIII. were all born in the palace, and the first of these kings died there. Henri IV., who greatly improved and embellished it, made it his favourite residence; as did also his daughter, Henriette, widow of Charles I. of England. Christina, the self-exiled queen of Sweden, lived here; and one of the galleries is still shown as the spot where she caused her unfortunate secretary, Monaldeschi, to be murdered. In 1685 the revocation of the Edict of Nantes was signed here; and in the following year the great Condé closed his career in the very room in which the eldest son of Louis XV. afterwards died. Pope Pius VII. was here confined prisoner for a year and a half by Napoleon; and in 1814 the emperor took leave of his guard, and signed his abdication of the French throne at Fontainebleau. The present emperor of the French sometimes resides here to enjoy the sports of the forest, which is well stocked with game of various kinds, especially wild boars. The beautiful gardens and ornamental waters immediately surrounding the palace form a great attraction to the Parisians, large numbers of whom arrange parties of pleasure to Fontainebleau during the summer months, especially on Sundays.

FONTAINES, PIERRE FRANÇOIS GUYOT DES (1685–1745), a French critic of considerable note. He was a member of the Society of Jesus, and held various ecclesiastical appointments, but at the age of thirty he renounced the church and devoted himself to literature. In 1724 he became editor of the *Journal des Sçavants*, which he did much to rescue from the discredit into which it had fallen. From the imputation of an infamous crime for which he was imprisoned he was saved by Voltaire; though between him and his benefactor there afterwards broke out one of the most bitter and disgraceful literary quarrels on record. Des Fontaines constituted himself the leader of an anti-Voltairean movement, and reviewed some of Voltaire's works with unjustifiable severity. That author retaliated, and exerted all his influence, political, literary, and social, to ruin his quondam friend. Even after Des Fontaines' death Voltaire strove to tarnish his memory, and held him up to ridicule in *Le Pauvre Diable.* Des Fontaines, however, had some of the qualities of a good critic. He possessed a solid judgment, quick insight, and very considerable learning. But he was neither impartial nor disinterested, and, as a writer, is little above mediocrity. His principal works are a prose-version of the *Æneid;* translations of various works of Swift and Pope; and some novels deservedly forgotten. He also contributed largely to the *Journal des Sçavants*, the *Nouvelliste du Parnasse*, and other periodicals.

FONTANA, FELICE, a distinguished physiologist and experimental philosopher, born at Pomarolo, a little town in the Tyrol, on the 15th April 1730. He began his studies at the neighbouring city of Roveredo, and continued them in the schools of Verona and Parma, and afterwards in the universities of Padua and Bologna. He then visited Rome, and went to Florence, where he obtained from the Emperor Francis I. who was at that time Grand Duke of Tuscany, the appointment of professor of philosophy at Pisa; but the Grand Duke Peter Leopold, who was also afterwards emperor, invited him to settle at Florence, and gave him an establishment connected with his household, as *Fisico* or naturalist, and as director of the cabinet of natural history, which was afterwards rendered by his exertions one of the principal ornaments of the city of Florence.

Fontana wrote many works on physiology, natural philosophy, and chemistry. In 1757 he was engaged in an investigation tending to confirm the doctrines of Haller respecting the irritability of the muscles, considered as a distinct quality inherent in those organs. Haller has published several of his letters as a part of his own *Mémoires sur les parties sensibles et irritables;* and the subject afforded Fontana the materials of several successive essays—*De Irritabilitatis legibus nunc primum sancitis*, Atti di Sienna, vol. iii., p. 209, 1767; *Ricerche filosofiche sopra la Fisica animale*, 4. Flor. 1775. This volume contains only the *Essay on the Laws of Irritability*, stating, first, the general outline of the doctrine, then entering into the different intensity of the property of irritability, and its loss by exhaustion or by inactivity, and discussing the action of the heart, and the peculiarities of death occasioned by electricity. Another link of the same chain of investigation is found in the earlier publication, *De' moti dell' Iride*, 8. Lucca, 1765; showing that the contraction of the pupil depends on the

Fontana. effect of light falling on the retina, and not on the iris itself, and establishing an analogy between the motions of the uvea and the semi-voluntary actions of the muscles of respiration. One of the most important of Fontana's works is his *Ricerche fisiche sopra 'l Veneno della Vipera*, Lucca, 1767; containing an immense multitude of experiments calculated to show that the poison of the viper acts by mixing with the blood, and destroying the irritability of the muscles to which it is conveyed; but that the bite of the *Vipera aspis*, though fatal to small animals, is scarcely ever capable of producing any immediately dangerous effects on the human frame. The same matter was republished with many additions in the *Traité sur le Vénin de la Vipère, sur les Poisons Américains, sur le Laurier-cérise, et sur quelques autres Poisons*, Berlin, 1787; together with some observations on the primitive structure of the animal body, experiments on the reproduction of the nerves, and remarks on the anatomy of the eye. In 1766 our author published an essay entitled *Nuove Osservazioni sopra i globetti rossi del sangue*, Lucca; confuting the assertions which had lately been advanced by Della Torre respecting the complicated structure and changes of form of the globules of the blood. In the next year appeared *Osservazioni sopra la ruggine del grano*, Lucca, 1767; describing an animalcule like an eel, to which he attributes the rust of coin, but which has not always been found by subsequent observers in similar cases, perhaps for want of accurate distinction. There is also a *Lettre sur l'Ergot, Journ. Phys.* vii., p. 42. The *Lettera sopra le Idiatidi e le Tenie, Opuscoli Scelti.* vi., p. 108, Milan, 1783, contains an account of the hydatids which produce the symptoms of vertigo in sheep. A *Lettre à* M. * * *, *Journ. Phys.* vii., p. 285, contains some remarks on the circulation of the sap in plants. In an essay *Sur le Tremella, Journ. Phys.* vii. p. 47, a zoophyte of a green colour, described by Adanson and others as a plant, is shown to consist of a multitude of little animals in continual motion.

Fontana entered also very minutely, but with more industry than accuracy or closeness of reasoning, into the chemical novelties which occupied so much attention throughout Europe in the latter half of the last century. He seems, however, to have had the merit of first applying the discoveries of Priestley respecting the effects of the nitric oxide to the examination of the qualities of the atmosphere by means of the eudiometer, which is the subject of his *Descrizione e usi di alcuni Stromenti per misurar la salubrità dell' aria*, 8. Flor. 1774, 4to, 1775, and is further illustrated in his *Recherches physiques sur la nature de l'air dephlogistique et de l'air nitreux*, 8. Par. 1776. He also observed the remarkable property that charcoal possesses of absorbing several times its bulk of different gases. In the *Ricerche fisiche sopra l'aria fissa*, 4. Flor. 1775, he is by no means equally fortunate, having fancied that the acidity of the fixed air is not essential to it, but accidentally derived from the stronger acid employed in expelling it from the earth or alkali. The *Philosophical Transactions for* 1779, p. 187, contain his *Experiments and Observations on the Inflammable Air breathed by various Animals*, consisting of a repetition of Scheele's attempt to breathe hydrogen gas, which did not always create a sensation of immediate uneasiness, though it was sometimes productive of alarming consequences. In the same volume, p. 432, we find an interesting *Account of the Airs extracted from different kinds of Waters, with thoughts on the Salubrity of the Air at different places*, showing that the air afforded by water is very different under different circumstances, but that the quality of the atmosphere itself scarcely ever exhibits any variations which can be rendered sensible by chemical tests.

To the Memoirs of the Italian Society Fontana contributed several short essays; the first, entitled *Principi generali della solidità e della fluidità dei corpi*, vol. i., p. 89, Verona, 1782, containing the prevalent theories of the day respecting the change in the forms of aggregation of the same substance, together with experiments on the elasticity of different gases. The second is a collection of definitions, entitled *Sopra la luce, la fiamma, il calore e il flogisto*, p. 104, characterizing these supposed elementary principles according to the ideas of Bergman, Scheele, and others. In a later volume, v. p. 581 (1790), we find a *Lettera del Cavaliere F. Fontana al Sign. de Morveau*, in which it is conjectured that inflammable air may be a compound of phlogiston and water, and it is observed that the white crusts of flints contain as great a proportion of pure silica as their internal parts. Our author remarks, however, that his attention had of late been much distracted from chemical pursuits by the attention required for the completion of his collection of wax models of anatomical subjects, and for the duplicates which he was preparing for the cabinet of Vienna at the request of the emperor. At a subsequent period another series of copies of these models was ordered by Bonaparte to be sent to Paris; but it was there judged inferior to the preparations already existing in the Ecole de Médécine, which had been made under the direction of Laumonier, and Fontana's collection was sent to the university of Montpellier. He was latterly engaged for some time in the preparation of a colossal model of a man, built up anatomically of all his component parts, which were accurately represented in wood; but this elaborate design was never completed.

Fontana was also the author of a few other chemical and mineralogical papers of less importance. His last work is entitled *Principes raisonnés de la Génération.* He was also meditating an essay on the revivification of animals, but he did not live to complete it. A collection of his works, translated into French by Gibelin, was published at Paris in 1785, entitled *Observations Physiques et Chimiques.* Fontana died March 9th 1806, and was buried in the church of the Holy Cross, not far from the tomb of Galileo. (Cuvier, in *Biographie Universelle*, vol. xv. 8. Par. 1816.) (T. Y.)

FONTANA, *Gregorio*, a profound mathematician and natural philosopher, younger brother of Felice Fontana, was born at Villa de Nogarola, near Roveredo, on the 7th December 1735.

He received the first rudiments of his education at Roveredo, and continued his studies at Rome, where he entered into the *Scuole Pie*, and soon distinguished himself by his talents and assiduity. He was entrusted with the care of a part of the public instruction in the school called the Collegio Nazareno, and was soon afterwards sent as a professor to Sinigaglia. It was here that he formed an intimacy with the Marquis Fagnani, whose example and assistance contributed very much to the advancement of his mathematical studies, to which he very soon in a great measure confined his attention. He was then removed by his superiors to Bologna; but his co-operation was found more necessary for the pious schools which had lately been established at Milan, and he there obtained the patronage and friendship of the Count de Firmian, the Mæcenas of the day, who greatly encouraged the publication of his first works. From these works he acquired so much credit, that he was summoned in 1763 to occupy the chair of logic and metaphysics in the university of Pavia; and he was appointed by Firmian director of the public library which he founded about the same time for the university. Two years afterwards he was advanced to the professorship of the higher mathematics, which had become vacant by the death of the celebrated Boscovich, and he filled this situation with high reputation for thirty years. In April 1795 he was elected a foreign member of the Royal Society of London. About this time his health began to decline, and his physicians considered him as having suffered from too great application to his studies. In 1796 he received great marks of respect from Bonaparte, then commanding the French

army in Italy; and he was made a member of the legislative body of the newly erected Cisalpine republic. In 1800, having resigned the professorship at Pavia, he came to Milan, and was afterwards nominated one of the Electoral College of the Dotti. He was still occupied in a variety of literary pursuits, when he was attacked by a violent fever, which caused his death at Milan, on the 24th August 1803.

Fontana's principal publications were seven Academical Dissertations on various departments of mathematical and mechanical science; a great variety of papers in the *Memoire della Società Italiana delle Scienze;* and numerous translations. (T. Y.)

FONTARABIA. See Fuente-rabia.

FONTENAY, or Fontenai, the capital of a cognominal arrondissement in the department of Vendée, France, is situated on the river Vendée, at the point where it becomes navigable, 35 miles S.E. of Bourbon-Vendée. The town is old and generally ill-built. It was formerly fortified and still has some remains of its castle, which belonged to the counts of Poictiers. The only remarkable object is the parish church, which has a spire 311 feet in height. It has manufactures of course linen and woollen cloths, and a considerable trade in timber and wines. Pop. (1851) 7348.

FONTENELLE, Bernard Le Bovier de, author of the *Eloges, Dialogues des Morts,* &c., was born at Rouen, Feb. 11, 1657, died at Paris Jan. 9, 1757, having very nearly attained the age of 100 years. His father was an advocate settled in Rouen; his mother was a sister of the great Corneille. He was educated at the college of the Jesuits in his native city, and distinguished himself by the extraordinary precocity as well as the amazing versatility of his talents. His teachers, who readily appreciated his abilities, were anxious to allure him into their order, but his father designed him for the bar, and he became an advocate. He lost the first cause which was entrusted to him to plead, and immediately after abandoned law for the more congenial pursuits of literature. In 1674 Fontenelle visited Paris for the first time, and began his literary career as a poet. He competed for three of the prizes offered by the French Academy for the best poems on certain prescribed subjects, but without success, despite the powerful influence brought to bear on his behalf. He had the additional misfortune to see his tragedy of *Aspar* damned, though, for the purpose of annoying Racine, his uncle Thomas Corneille had already sounded forth his praises in the *Mercure* as the most gifted of the rising dramatists of France. Fontenelle afterwards acknowledged the justice of this sentence by burning his unfortunate drama, of which nothing but the name now survives. Still undaunted by his failures, he persisted in the belief that poetry was his true vocation, and produced a number of operas and comedies, the mediocrity of which, considering the author's real talent, is positively astonishing. His opera of *Thétis et Pelée,* though highly praised by Voltaire, is little superior to the others. Of all his dramatic works, seventeen in number, not one has kept the stage. His *Poésies Pastorales,* with equally small claim to permanent repute, are striking from their novelty and the extravagant conceits in which they abound. They exhibit neither sentiment nor nature; the shepherds are all *bergers de salons.* His Hylases and Sylvanders speak like the wits of the Hôtel Rambouillet. The utmost that can be said for his poetry in general is that it displays much of the *limæ labor,* great purity of diction, and occasional elegance and elevation of sentiment. The *Dialogues des Morts,* Fontenelle's first real title to literary renown, was published in 1683. This was a remarkable work for the era in which it appeared, and contains much fine and ingenious thinking, along with much that is wire-drawn and paradoxical. Three years later (1686) appeared his *Entretiens sur la pluralité des Mondes,* which, in the words of D'Alembert in the general preface to the *Encyclopédie,* was the first work "qui ait appris aux savants à secouer le joug du pédantisme." Voltaire pronounced it "le premier exemple de l'art délicat de répandre les graces jusque sur la philosophie," and, in the verses which he afterwards wrote on its author, characterized its happy combination of science and wit in the line—

"L'ignorant l'entendit, le savant l'admira."

It was precisely such a work as Fontenelle was capable of executing well, both from the natural bent of his intellect, and the course of his previous studies. His object was to popularize among his countrymen the astronomical theories of Descartes, and it is to be doubted if that philosopher ever ranked a more ingenious expounder among the number of his disciples. The pointed and happy illustrations with which Fontenelle has interspersed this essay are as amusing as they are instructive to the reader, and though some of the ideas advocated in it are rather startling, and sometimes quite opposed to received opinion, they are so plausibly stated, and set in so obvious a light, that they are at once adopted as old and familiar truths. In 1687 Fontenelle published his *Histoire des Oracles,* a book which made a considerable noise in the theological as well as the philosophical world. It was not so much an original work as a redaction from the Latin of Van Daale, and consisted of two essays, the first of which was designed to prove that oracles were not given by the supernatural agency of demons; and the second, that they did not cease with the birth of Christ. The clearness and precision of the style, and the naturalness and regularly progressive flow of the reasoning in this treatise, have been always much admired. It excited the suspicion of the church, however, and a Jesuit, by name Baltus, published a ponderous refutation of it; but the peace-loving disposition of its author impelled him to leave his opponent unanswered.

In 1691 Fontenelle was received into the French Academy in spite of the efforts of Racine and Boileau, who on four previous occasions had secured his rejection. In 1708 appeared the first edition of his *Eloges historiques des Académiciens,* the work by which he is best known to posterity. In these *Eloges,* which are at once biographical and critical, the author has so happily blended history and encomium that the formal character of the composition is quite lost sight of, and the eulogy is managed with such delicate tact that it is greatest where it seems least intended.

The only other works of Fontenelle that remain to be mentioned are his *Géométrie de l'Infini,* and his *Apologie des Tourbillons,* treatises which display rather a calm spirit of philosophy than strong scientific powers.

Fontenelle is likely to be remembered by posterity as much from his splendid social qualities, and the brilliancy and variety of his acquirements, as from the enduring value of his works. He combined in a singularly happy degree the philosopher and the man of fashion. As a writer, he strikes at first sight by his universality. Voltaire pronounced him the only universal man of the seventeenth century. He was in his own era very much what that writer was in the subsequent one. Without the restless energy and martyr spirit that distinguished Voltaire, Fontenelle nevertheless achieved noiselessly a great result. The vast extent of his reading gave him a thorough command of happy and pertinent illustration; and the perfect clearness and definiteness of his views on every department of science, joined to his high literary powers, enabled him to throw open to the multitude the gates of science, which till his day none but the scholarly few had possessed the secret of unlocking. This result was attained in a manner so simple and so noiseless that it did not appear to be the work of any individual agency so much as the natural growth of circumstances. Though Fontenelle cannot claim the merit of having made any great discovery, or contributed to the general store of positive knowledge, yet he sowed the seeds of that spirit of

free inquiry into the principles of religion, politics, and morals, which sprang up at the close of the seventeenth century, and which (in some departments at least) have not yet attained their full bloom and verdure.

Fontenelle's mind was eminently well-balanced. He was at once bold and circumspect, cool in temperament yet with wide sympathies, independent but not strongly opinionative; in a remarkable degree, as Voltaire remarked, *discreet.* In theory he was an egotist, in practice a man of much benevolence, and his large means enabled him to do a great deal of good with very little noise. He used to boast of being worse than he really was, and though his actions always belied his words, he has had the misfortune to be more generally judged by his words than his actions. He was perhaps the first man that ever said on the approach of death that if he had his life to live over again he would do exactly as he had done before. On his death-bed he consoled himself by remarking "I am a Frenchman; I have lived a hundred years, and I never threw the slightest ridicule on the smallest virtue." The calmness with which he met his death was in keeping with the serenity of his life. He merely observed, "Je ne souffre pas, mes amis; mais je sens une certaine difficulté d'être."

There have been several collective editions of Fontenelle's works, the best of which are those of Paris, 8 vols. 8vo, 1764; and 5 vols. 8vo, 1825. Some of his separate works have been very frequently reprinted.

FONTENOY, a village of Belgium, province of Hainault, five miles S.E. of Tournay, and celebrated for the victory gained there, in 1745, by the French under Marshal Saxe, over the allies commanded by the Duke of Cumberland.

FONTEVRAULT, *Order of,* a religious order instituted about the end of the eleventh century, and taken under the protection of the holy see by Pope Pascal II. in 1106, confirmed by a bull in 1113, and invested by his successors with very extraordinary privileges. This order, which consisted of both monks and nuns, was under the superintendence of an abbess. The order was divided into four provinces, which were those of France, Aquitaine, Auvergne, and Bretagne, in each of which they had formerly several priories. In 1804 this ancient abbey was converted into a prison.

FONTINALIA, in *Antiquity,* a festival celebrated by the Romans on the 13th October in honour of the deities who presided over springs and fountains.

FOOD.

THE subject of human food may perhaps be most conveniently considered under the following five heads:—

I. The chemical composition and the physiological action of the various proximate principles of animals and vegetables commonly employed as food. II. The varieties of animals and vegetables used as food in this country, the different alimentary products obtained from them, and their various composition. III. The modes of preparing food for use, and the *rationale* of their respective actions. IV. The modes of preserving articles of food from decomposition. V. The principles of diet, and some dietary tables.

I. *The chemical composition and the physiological action of the various proximate principles of animals and vegetables commonly employed as food.*

The different proximate principles (*i.e.*, specific unions of some of the elementary bodies of chemistry[1]) of animals and vegetables that may be used as food, and become converted into blood for the purpose of keeping up in adults the constant waste of the tissues, and for the same purpose and also for affording the additional matter that is required in growing individuals, have been, since the publication of Dr Prout's treatise, usually arranged into three classes and water. These three classes are—the saccharine, the members of which are composed of carbon, hydrogen, and oxygen, the two latter being combined in the same proportion that they are in water; the oleaginous, which likewise consists of the same elements, but in which the hydrogen and oxygen are not in the same proportion that they exist together in water; and the albuminous, which are essentially composed of the four elements of carbon, hydrogen, oxygen, and also nitrogen, the last-named element being almost invariably in the proportion of about fifteen per cent. But, besides these four elements, the human body, and therefore the nutritious parts of animals and vegetables that keep up that body, contain, although in small proportions, sulphur, phosphorus, sodium, chlorine, &c. The manner in which these elementary bodies are, in animal and vegetable structures, combined, is certainly not ascertained, and the subject will be partially considered by-and-by, when noticing Mulder's theory of proteine compounds, but they may, for all practical purposes, be stated to be combined with the albuminous proximate principles.

A. *Saccharine proximate principles derived from vegetables.*—1. *Cellulose.* The basis, or skeleton, as it were, of vegetable structures, is either cells, or vessels that are in fact composed of a number of ruptured or elongated cells. The walls of these cells are composed of the proximate principle under notice—cellulose. In order to separate it from the other constituents of the vegetable, it is necessary to cut the stem into small bits and digest them (for the purpose of separating the other constituents of the wood) successively in alcohol, ether, potassa water, hydrochloric acid, and water. Cellulose is not soluble in any of these, while the other constituents of the stem are, and hence cellulose is left behind. It is a white substance, but is changed into a violet colour if iodine be added to it. Its composition[2] is as follows: 24 atoms of carbon, 21 of hydrogen, and 21 of water. By the action of acids or of heat it is converted into starch, and therefore if a little sulphuric acid be added to it, the violet colour produced by the iodine (see next paragraph) is converted into a blue. Substances that contain a very large proportion of cellulose are not employed as human food, but such (as hay and straw) are much used in feeding cattle and horses; and when this is done, it is probable that the cellulose is converted into starch by the hydrochloric acid of the stomach. Cellulose is apt in old plants to part with a portion of its oxygen, and is then converted into a principle named lignine. This is known from cellulose by its solubility in caustic potassa water. As its hydrogen and oxygen are not united in the proportions that they are in water, it is not exactly a saccharine proximate principle. It exists in potato skins, the peel and core of fruit, the seed-coat or skin of nut kernels, &c., and it seems doubtful if it can afford food. The principle said to have been detected in mushrooms (and which perhaps also occurs in other cellular plants)—fungine, is probably a variety of lignine or of cellulose. Braconnot,[3] however, reports that it contains nitrogen. 2. *Starch.* In plants that have come nearly to maturity, starch is probably the proximate principle that, next to cellulose, is most abundant. It is also contained in large quantities in many ripened, indeed in most ripened

[1] The body of man, as will be more fully explained in section v., consists of carbon, oxygen, hydrogen, nitrogen, sulphur, phosphorus, chlorine, iron, sodium, calcium, potassium, magnesium, and fluorine. As the body cannot *form* an element, of course the food must contain and consist of these elements.

[2] Johnston.

[3] *Anal. Chem.,* 79.

or matured ones. It is easily obtained from flour (or ground cereal grains); the tubers of potatoes; the stem of the sago-palm, &c., &c. If any vegetable structure that contains starch be washed with cold water upon a sieve, a milky fluid passes through, which, when set aside, deposits a white powder. This is starch. Starch is, when pure, without taste, colour, or smell. It does not dissolve in cold water, but does so very readily in hot; and, when this is the case, it forms, upon cooling, a gelatinous mass. When moistened with a solution of iodine, it strikes a blue colour. Its formula is 12 carbon, 10 hydrogen, and 10 oxygen; or 24 carbon, 20 hydrogen, and 20 oxygen. It therefore differs from the cellulose, from which it is probably derived, in containing one atom less (or the atoms that contain one atom less) of water. The *rationale* of the action of sulphuric acid, when it converts cellulose into starch, is that it abstracts from it this one atom of water. There are two subvarieties of starch, called *inuline* (obtained from the dahlia, and other roots), and *lichen* starch (which is procured from the lichen). They differ from common starch in their action upon iodine, in their relations to water, and in a very slight degree in the proportion in which their elements are arranged. But for all practical purposes these variations may be disregarded. 3. *Dextrine.* If starch be heated up to a temperature of 300°, or if diluted sulphuric acid be added to it, or indeed if it be boiled in ordinary water for some time, a proximate principle—*dextrine*—is obtained, which differs from starch in being soluble in cold water. This change of starch into dextrine is naturally brought about during the germination of those seeds that contain starch. In this case the change is brought about by the contact of a peculiar nitrogenous principle—diastase—soon to be noticed. This principle may be separated from barley that is being converted into malt in the malt-house, and if a little of this separated principle be added to any starch, it (the starch) is soon converted into dextrine—a substance that, although having the same chemical composition as starch, unlike that principle, is soluble in cold water. This conversion of starch into dextrine is brought about in nature by the action of diastase during the germination of those seeds that contain starch. The albuminous proximate principle of diastase will be afterwards noticed, and if a little of it be added to starch, the starch is speedily converted into dextrine. If sulphuric acid be added to dextrine, the dextrine is converted into another proximate principle of this group—sugar. The formula of dextrine is of course the same with that of starch. 4. *Gum.* Many vegetables secrete gum, of which proximate principle there are two varieties, which merely differ in the one, arabine, dissolving in cold, and the other, cerasine, requiring hot water for its solution. The chemical composition of gum is identical with that of dextrine and of starch, but gum differs from the latter in not giving the blue colour with iodine, and from the former in not readily giving up some of its oxygen and hydrogen to sulphuric acid, being thereby converted into sugar. 5. *Cane Sugar.* Many plants, as the sugar-cane, the maple, the beetroot, &c., contain another proximate saccharine principle, *cane sugar.* This is soluble in water, forming with it an oily compound—*syrup*—from which, however, the sugar gradually separates in crystals, which are commonly known as sugar-candy, and which sugar-candy has an extremely sweet taste. Its formula is 24 carbon, 18 oxygen, and 18 hydrogen. If diluted sulphuric acid, as before mentioned, be added to starch, first dextrine is obtained, and then cane sugar. And when cane sugar is itself heated with dilute sulphuric or other acids, it is blackened by it, and becomes converted into another form of sugar, next to be noticed. 6. *Grape Sugar.* This is found in the grape, apple, and many other fruits, and is produced from cane sugar by the action of acids and heat. In this latter mentioned manner it is extensively produced, when a solution of malt, &c. is fermented by the brewer or distiller. Grape sugar is neither so soluble in water nor so sweet as cane sugar. Its formula, too, is different, being 24 carbon, 22 hydrogen, and 22 oxygen; and it may be readily distinguished from cane sugar by not being blackened when boiled with diluted sulphuric acid. Other subvarieties of sugar may be omitted. One called pectine is contained in many fruits and roots, and contains an excess of oxygen. Combined with sugar, it forms a jelly. 7. *Alcohol.* Correctly speaking, this proximate principle does not belong to the purely saccharine group, for its atoms of hydrogen are in excess over those of oxygen. Neither does it, like all the above mentioned saccharine proximate principles, exist ready formed in plants, although by art,[1] when the plant has been some time dead, they can be converted into alcohol. In order to procure alcohol there must be a solution of grape sugar (or of cane sugar, dextrine, or starch, under those conditions in which these respective principles may become converted into grape sugar), a certain temperature, and the presence of some albuminous matter, as gluten (as in grapes), or yeast, as in beer-making, or the like. When these conditions occur, carbonic acid is given off, and alcohol is left in the water. The following is the change that occurs:—1 atom of grape sugar and 2 of water are composed of 24 carbon, 24 hydrogen, and 24 oxygen. If we subtract from this 4 atoms of carbonic acid, which contain 8 of carbon and 16 of oxygen, we have left 2 atoms of alcohol, which together contain 16 atoms of carbon, 24 of hydrogen, and 8 of oxygen. The formula of alcohol is therefore 8 of carbon, 12 of hydrogen, and 4 of oxygen. Obtained in this manner alcohol is always much diluted, constituting wine, beer, &c. To obtain it in a purer form it requires to be distilled and rectified.

B. *Saccharine proximate principles derived from Animals.*—1. *Milk Sugar.* If the milk of any mammiferous animal be taken, and the curd separated, as is done in ordinary cheese-making, and then the whey boiled so as to evaporate a considerable portion of the water, the remaining whey gradually deposits a number of crystals, which, on examination, are found to be a variety of sugar, to which the name of milk sugar is given. It is not so sweet to the taste as either cane or grape sugar, neither is it so soluble in water, and it is harder and grittier when chewed than they are. Its formula is 24 carbon, 19 hydrogen, and 19 oxygen. By the action of acids it is converted into grape sugar, and is then susceptible of the alcoholic fermentation. Milk sugar is never sold in this country except for scientific purposes; but in Switzerland it forms an article of commerce, and it is the source of the alcoholic drink of some nomadic tribes. In this last-mentioned case the lactic acid (see p. 758) is allowed to separate, the free lactic acid then converts this sugar into grape sugar, and the albuminous principle of the curd or cheese acts as a ferment. The physiological action of all the saccharine proximate principles is the same, and consists altogether, or mainly, in affording carbon, and this almost solely for the purpose of keeping up the animal heat, and not for the purpose of depositing fat. Man requires to keep up a temperature of about 100° Fahr., which is one much higher than that of the atmosphere that surrounds him. In order that he may do this his economy is able to take the carbon of his food, including, of course, the carbon of the saccharine principles that constitute his food, and combine it, just as wood, or coal, or coke are combined in a common fire, with oxygen (which oxygen man and animals take in at the lungs from the air). The result is, in this as in all ordinary cases of combustion, the formation of carbonic acid by the union of the carbon of the food and the oxygen of the air; and this carbonic acid, when the elements that composed it have served their purpose of heating the body, is cast out at the lungs. The amount of pure carbon necessary to be taken in as food by an ordinary-sized adult man for the purpose of burning in him is about eleven ounces a-day. But some of this may be derived, and in many cases is, from the oleaginous proximate principles now to be noticed.

C. *Oleaginous proximate principles derived from Vegetables.*—Plants usually, and, as far as regards those used as food, almost without an exception, contain a considerable quantity of oily matter. This is usually deposited around the seeds, as in the husks of cereal grains, or among the cellular tissue, as in turnips, potatoes, grass, &c. When fixed oily matter is present in considerable quantity in a vegetable, it may be generally separated by means of pressure, or, if that is not convenient, by being dissolved out by means of ether, and the ether afterwards evaporated. Volatile oils are readily obtained by distillation with water. The fatty matters that can be thus obtained from plants may, for all practical purposes, be ar-

[1] Alcohol is, however, sometimes produced in nature. Very ripe gooseberries, and probably grapes, and many other very ripe but ungathered fruits contain it.

ranged into three, viz.—1. *Elaine*, which is a liquid, and may be readily procured from the solid constituent of olive and other oils by freezing. The part, in such a case, that is left fluid is the elaine. There are two sub-kinds of it, one that is not acted upon by the air, and another that, when exposed to the air, absorbs oxygen, and undergoes other changes, the result of which is to convert it into a resin, or oxygenated oil. This latter is the drying oil of painters. The composition of the two kinds is identical, their formulæ being 94 carbon, 87 hydrogen, and 15 oxygen. 2. *Margarine.* This is the solid portion that is left when most vegetable oils are frozen. It is white, hard, and brittle, and melts at 118°. The composition is 74 carbon, 74 hydrogen, and 12 oxygen. 3. *Stearine.* This is very analogous to the preceding, and is obtained by freezing some vegetable oils (not, however, many), of which it constitutes the solid part. It differs from margarine in containing less oxygen, and in requiring a higher temperature (129°) to melt it. These oleaginous principles are usually mixed together in vegetables, and likewise contain small quantities of some essential oil peculiar to each plant, to which the odour and sapid taste are often owing.

D. *Oleaginous proximate principles obtained from animal articles of food.*—1. *Elaine.* This is the liquid part of almost all animal fats, and is quite identical with vegetable elaine. 2. *Margarine.* This is the solid part of the fat of man, the goose, cows, &c. It is the same as vegetable margarine. 3. *Stearine.* This is the solid part of the oily matter of cattle, sheep, pigs, and other animals, and in no respect differs from stearine obtained from vegetables. Animal oils, like vegetable oils, often contain a minute proportion of some oil peculiar to the animal, upon which their peculiar odour, sapid taste, &c., depend. These three oleaginous proximate principles of vegetables and animals are now, however, known to be compounds of elaic, margaric, and stearic acids with oxide of glycerine. For the properties and compounds of these substances see CHEMISTRY. The physiological action of the oleaginous proximate principles of plants and animals whose structures are used as food is, like those of the saccharine group, to furnish carbon, partly for the purpose of being consumed as food, and partly to furnish fat. Indeed, under ordinary circumstances, they only fulfil the latter indication. Nations the members of which, as Greenlanders, &c., have a small supply of saccharine proximate principles either to eat or to convert into alcohol, consume a large amount of animal fat. They have little or no vegetable fat; and something of the same kind has been observed to be the case with individuals in other nations who can obtain saccharine proximate principles, but who, from some reason or other, do not.

E. *Albuminous proximate principles obtained from vegetable articles of food.*—1. *Vegetable Albumen.* If the expressed juice of many plants, as of the potato, turnip, carrot, the seeds of the cereal grains, &c., be filtered, and the fluid that remains be exposed to a heat of 180° Fahr., a portion of it coagulates and falls down in flakes. This is albumen, and may be collected upon a filter. Albumen may be distinguished from other nitrogenous proximate principles by coagulating at a heat of about 180°, by drying into a hard white mass, by being soluble in alkalies, and by being precipitated from these alkaline solutions by all acids save the phosphoric and acetic. It is believed that albumen exists in plants in two states, one a soluble one, and another not so. Albumen essentially contains carbon, oxygen, hydrogen, and nitrogen. The exact proportions of these are perhaps not very accurately ascertained. The following is the result of an analysis by Jones:[1]—

Carbon, 54·74; hydrogen, 7·77; nitrogen, 15·85; oxygen, 21·64 = 100.

2. *Gluten.* If the flour of wheat or other cereal grain, or indeed of many other parts of several plants, be made into a dough with water, and the dough well washed, the saccharine and oleaginous matters, and also the albumen, are carried away by the water, and a stiff tenacious substance is left. This is gluten. It is, as the mode of obtaining it sufficiently indicates, insoluble in water, but it is partly so in alcohol. The portion that does so dissolve in alcohol is called glutin, and sometimes vegetable fibrine. The chemical composition of gluten is very analogous to that of albumen, out of which it is probably formed. Gluten does not coagulate at a heat of 180°, it dissolves in acetic acid, and may also be distinguished from other proximate albuminous principles by its great tenacity. 3. *Vegetable Caseine.* After boiling the sap of some plants, as of potatoes, pears, &c., and straining the liquid that remains from the albumen that is by the heat coagulated, if a little hydrochloric (or other acids) be added, a white powder gradually falls to the bottom. This is caseine. Its chemical composition probably differs but slightly from those of albumen and gluten, but it may be known by its coagulating in many acids. 4. *Theine.* If tea, coffee, or cocoa be boiled in water, and the solution treated with sugar-of-lead, this proximate principle, theine, which had been combined with tannic acid, is thrown down in brilliant long crystals of a silvery lustre. It is composed of carbon, oxygen, hydrogen, and nitrogen, but the latter is in greater proportion than in any other albuminous compound (it actually contains 29 per cent. of this element), and, as we shall afterwards see, this accounts for the nutritious effect of tea, &c., in individuals who consume little food of other descriptions. 5. *Diastase.* If pounded malt be infused in cold water, the solution considerably evaporated, and then alcohol added, a white powder falls down, to which the name of diastase is given. Diastase exists in all *germinating* seeds or tubers, and is probably during germination the last product obtained from the above-mentioned albuminous principle caseine. If a little of this diastase be applied to starch it has the remarkable property of converting it, first of all into (soluble) dextrine, and eventually into grape sugar. Diastase is an albuminous proximate principle, but its exact composition is not known, one reason for this being that it is very readily decomposed and separated into inorganic compounds, one of these being ammonia. The very important action that it has in ripening and maturing vegetable productions is ascertained, but in this place we have only to consider its action in fermentation. It is not known if diastase in itself furnishes nutriment or not.

F. *Albuminous proximate principles obtained from animal articles of food.*—*Animal Albumen.* This constitutes the white of the egg, or it may be readily obtained by heating the serum of the blood up to 180° (Fahr.), upon which it coagulates and falls down in flakes. It is also abundant in almost all animal tissues. It is probably exactly identical in all its properties with vegetable albumen. 2. *Fibrine.* If recently drawn blood be whisked with a birch wand, a white fibrous matter attaches itself to the twigs. This is fibrine. It may also be obtained by a little management from any muscular structure. It differs (besides in other respects) from albumen in coagulating at ordinary temperatures, and from gluten (to which principle it is very analogous) in coagulating at all. Its formula is carbon 52, oxygen 23, nitrogen 16, and hydrogen 7. It is probably formed in animals out of albumen. 3. *Gelatine.* This may be obtained by boiling bones, skin, cartilage, &c. in water, and putting the solution to cool. It is distinguished from the two former substances by dissolving readily in hot water, and by this solution forming a jelly-like mass when cold. It also combines with tannin and forms the impervious compound called leather (which contains also fibrine). Gelatine is probably formed out of fibrine, and in its chemical constituents is nearly identical with that compound, but it contains a little more oxygen. It is important to recollect that pectose, which is sometimes called vegetable gelatine, is not an albuminous compound at all. 5. *Kreatine.* Some years ago Chevreul announced the presence in butcher meat of a crystallizable principle to which he gave the name of kreatine. It is, however, almost certainly the product of decomposition, and in no degree nutritive. 6. *Osmazome.* Cooked animal meat has a very different smell and taste from the same when raw. If the former be treated with alcohol, an odorous and sapid extract is obtained, to which the name of osmazome has been given. If this be a proximate principle, it is almost certainly an albuminous one, but it is very doubtful if it is such. It is perhaps a compound of lactates with the salt employed in cooking, but it may be that part of it is a resin obtained by the deoxidation of some of the fat during the application of heat. 7. *Proteine*, and the ashes of vegetable and animal structures that are used as food. If the structures of vegetables and animals that are used as food be examined, they are found to consist of an aggregation of several of the above proximate prin-

[1] *Annalen der Chimie.*

ciples (or of slight modifications of them that are purposely omitted), of water, and of a small quantity of salts, or of the acids and bases that form salts. If any of the substances that we use as food be exposed to considerable heat, the water is first driven off, the four elements in the proximate principles just noticed enter into new combination (carburetted hydrogen, ammonia, &c. &c.), and pass off into the air, but a small quantity of ash is left behind. In plants this ash is found to consist of sodium, potassium, chlorine, phosphorus, sulphur, calcium, magnesium, iron, silicon. In animals the constituents of the ash are the same, with the exception that animals contain no silicon. In the undestroyed structures of vegetables and animals these constituents of the ash probably exist as chlorides, phosphates, and sulphates of soda, potassa, &c. (or chlorides, phosphurets, and sulphurets of sodium and potassium), iron, &c. It has been maintained that the albuminous proximate principles are in reality compounds of a peculiar substance, to which the name of *proteine* has been given, and that the difference of the albuminous compounds essentially consists in their being respectively combined with varying portions of these constituents of the ash. This opinion is perhaps not supported by sufficient evidence, but the elements that form the ash may be considered as in some way or other united during life with the albuminous proximate principles of vegetables and animals.

G. *Acids found in the recently dead structures of plants and animals that serve for food.*—a. *Acids derived from vegetables.*—1. *Acetic acid.* This acid and the following (the lactic) resemble the saccharine proximate principles in being composed of carbon, hydrogen, and oxygen, and in the hydrogen and oxygen being in the same proportions as they exist in water. But they differ in this that they have an acid reaction, reddening litmus paper, and forming neutral salts with alkaline bases. Acetic acid as formed during the germination of seeds, is a product, at least often, of incipient putrefaction in many plants, particularly in those that had contained much sugar, but it probably also is contained in many living juices. Acetic acid (undiluted) consists of 4 carbon, and 3 respectively of hydrogen and oxygen. One of its chemical characteristics is that its solution gives a white precipitate (acetate of silver) with lunar caustic, and that this pricipitate is little soluble in water. Acetic acid is also obtained abundantly from the fermentation of wéak alcohol and the destructive distillation of wood. 2. *Lactic acid.* If chopped cabbage, flour, grains, or many other vegetable substances, be allowed to ferment, the starch or sugar is decomposed, and lactic acid is formed. The composition of it is carbon 6, hydrogen 6, and oxygen 6. It is also formed in animal structures that are beginning to undergo putrefaction. It perhaps never occurs in a living plant or animal. It appears, however, to be certainly an aliment. 3. *Tartaric acid.* This and the following consist of carbon, hydrogen, and oxygen, but they have the last-mentioned element in excess. They have acid reactions, but may be regarded otherwise as corresponding with the oleaginous principles of food. Tartaric acid exists in the juice of the grape, tamarind, and other fruits. In combination with potassa (argol), it is deposited in wine-casks and bottles. Its composition is carbon 4, hydrogen 2, and oxygen 5. 4. *Malic acid.* This acid exists in large quantities in apples, pears, and other fruits, particularly before they are ripe, or in those varieties of them that never become very ripe or sweet. Its composition is carbon 4, hydrogen 2, and oxygen 3. b. *Acids derived from animals.*—1. *Lactic acid.* If milk be allowed to stand for a while, it becomes sour. This is owing to its sugar, or a part of its sugar, having become converted into lactic acid, a substance identical with that noticed above, as being formed by the decomposition of cabbage, &c. It is also formed in flesh undergoing incipient putrefaction. 2. *Butyric acid.* This acid exists in butter, a substance that contains likewise two other acids, the consideration of which may be here omitted. 3. *Inosinic acid.* This acid perhaps exists in flesh just beginning to putrefy.

H. *Composition and physiological action of the different parts of animals and vegetables usually employed as food, and which contain two or more proximate principles.*—a. *Vegetable structures.* The various nutritive principles are generally so much combined in vegetables that a very few lines may suffice for this section. The stem of young edible plants is usually composed of cellulose, oil, some sugar and starch, and a small quantity of albuminous matter. The seed of the cereals, besides starch, a little sugar, and gum, contains a large amount of albuminous matter, surrounded by a husk that is very rich in oil. Esculent roots and tubers generally contain an admixture of albuminous matter, saccharine (usually starch), and oleaginous, the two last usually preponderating. Ripe fruits, besides albumen and oil (this in general very sparingly), contain sugar in considerable amount, and usually one or more acids. Unripe fruits consist almost entirely of cellulose and acids. All of these have also a large quantity of water mixed up with their structures. b. *Animal structures.*—1. *Bone.* This substance consists of about 33 per cent. of albumen and gelatine, principally the latter, and about 67 of phosphate of lime and other commonly-termed inorganic matters. The long bones also contain marrow, a substance which is a mixture of elaine and stearine. The bones of young animals contain a much larger proportion of the gelatine than those of old ones of the same species. 2. *Cartilage.* This consists almost entirely of gelatine and albumen, and is analogous to bone that has been deprived of its inorganic matter. 3. *Cellular Tissue.* This consists of cells that are composed of an albuminous principle, probably gelatine, and which inclose elaine and margarine. When the cells are very much filled with the fatty matter, the compound is named adipose tissue, or commonly fat, and a variety of it suet. 4. *Muscle.* The flesh of animals consists of muscle proper or lean, and also, in all or nearly all animals relished as food, of fat, which is deposited in the cellular tissue surrounding the fibres, and also that surrounding the entire muscles, which then often becomes adipose tissue. Some albumen, too, derived from the blood is contained amongst it, and of course various saline matters. As before mentioned, the kreatine found in dead meat is probably the first stage of decomposition, and the osmazome present in cooked meat developed by that process. Muscle contains about 74 or more per cent. of water. 5. *Glands and Viscera.* The tongue, the kidney, the sweetbread, and other internal organs, are used for food. They generally contain a good deal of albumen and fibrine. Sweetbread contains 6 per cent. of gelatine, liver has a peculiar brown oil, and the kidneys certainly often appear to retain urea. 6. *Nervous Matter.* Nervous matter contains albumen, various fatty matters, a peculiar acid that contains about 2 per cent. of nitrogen, various saline ingredients, and about 80 per cent. of water. Nervous matter is very little employed as food, being only occasionally used as a garnish. 7. *Blood.* Blood constitutes so great a proportion of the structure of animals, that some is almost invariably retained in the muscular structure. But blood is only used by itself as an article of food in the form of black puddings, which consist essentially of cooked hog's blood. Blood in composition and in nutritive quality is analogous to flesh.

II. *The varieties of animals and vegetables used as food in this country, the different elementary products obtained from them, and their various composition.*

A. *The varieties of Alimentary Vegetables.*

a. *Cereal Grains.*—1. *Wheat* (*Triticum*). The grain of wheat has for a very long time constituted an important article of food, and in England has for about three centuries been the staple grain. The kind usually cultivated is the *Triticum sativum.* A bushel of it should weigh, if very good, about 64 lb. Wheat in the form of flour is sometimes manufactured as macaroni and vermicelli; but its almost universal use is as bread. (See BAKING). The following is the composition of first-class wheaten flour:—Water, 14·0; albuminous compounds, 14·6; oil, 1·2; saccharine compounds, 66·9: cellulose, 1·7; ash, 1·6. The greater part of the ash is made up of phosphorus, potassium, and magnesium. The bran contains much less saccharine matter, but absolutely more oil and more albuminous matter; and "seconds" in this respect stand intermediate between fine flour and bran. The cheaper price of seconds and bran, therefore, appears to be somewhat arbitrary and improper, and brown bread is probably more economical than that made from fine flour. The objection to it is probably that bran does not leaven particularly well. 2. *Oats* (*Avena sativa*). In Scotland, the climate and soil of which seem peculiarly adapted to its cultivation, this cereal has long constituted the staple article of diet. This is also the case in the high-lying land in the West Riding of Yorkshire and the adjacent parts of Lancashire. A bushel of good oats weighs about 45 lbs. Oats are made into flour or meal, and before being submitted to the mill they are always kiln-dried, to facilitate the separation of the husk. The proportion of husk is

perhaps about a quarter per cent. When the husk is separated, but before the grain is ground, the seeds receive the name of groats. When ground the dust constitutes oatmeal, and it is found in practice that oats afford about half their original weight of meal, the loss being the water expelled by the kiln-drying, the husk, and the chaff. The following is Norton's analysis (the arrangement being altered) of oats that had been dried to 212°. Perhaps in this drying the loss of water would be about 20 per cent. Albuminous compounds, 19·91; saccharine do., 68·68; oleaginous do., 7·33; husk, 2·28; ash, 2·60. The proportion of ash, principally phosphates and sulphates of lime, potassa, and magnesia, is sometimes in much larger quantity. Oatmeal, therefore, contains considerably more nutritious matter than the same weight of wheat flour. The husks consist mainly of cellulose, and are almost never used as human food. 3. *Rye* (*Secale cereale*) has been cultivated from time immemorial, and was for long much used for breadmaking in this country, as it still is (constituting the staple) in Russia, many parts of Germany, &c. A bushel of rye weighs about 54 lb. Rye grain is very coarsely powdered, and the mixture of flour and bran made into fermented bread, which is distinguished from other bread by its black colour. The following is an analysis of rye flour, the water having been previously expelled. Albuminous compounds, 10·5; saccharine do., 78·0; oil, 3·5; salts, 6·0, principally phosphates of potassa, soda, and magnesia; loss, 2·0=100·0. These three cereal grains constitute the basis of the food of the modern European nations. In order that wheat may produce a good crop, it requires land rich in alumina, and also considerable summer heat; while rye thrives best on sandy soil. The oat does best with a dampish and somewhat cold climate, and seems to almost prefer a thin soil lying over primitive and metamorphic rocks. 4. *Barley* (*Hordeum distichon*). Barley is occasionally made into bread; and it is also used, when deprived of its husk, for making soup. But by far the most important use of barley is that it may be converted into malt (*i. e.* that its starch may be converted into sugar), for the purposes of brewing and distillation. The reason it is thus selected is, that of all grains, if put under the conditions favourable to germination, its diastase soonest converts the starch into sugar. A common weight of a bushel of good barley is 56 lb. It contains about 68 per cent. of starch, upon which its value to the maltster or distiller mainly depends. 5. *Rice* (*Oryza sativa*) supplies in the Eastern world the place occupied in the Western by wheat, oats, and rye, and is also pretty extensively used on a small scale in this country. The following analysis of rice is abstracted from Payen;—Albuminous principles, 7·5; saccharine do., 87·3; oil, 0·8; salts, 0·9; woody tissue (cellulose), 3·4. Thus, save in saccharine proximate principles, rice is far less nutritious than any of the preceding. 7. *Indian corn* (*Zea mais*) is the staple of North America, Mexico, &c., and has been, in times of scarcity of our own cereals, beneficially imported into this country. It is also sometimes, but precariously, cultivated in England. According to Payen, 14 or 15 per cent. of water having been previously expelled, the grain contains more than 12 per cent. of albuminous matters, nearly 72 of saccharine, and the immense proportion of 9 of oleaginous. It is, therefore, extremely nutritive.

b. *Viniferous Vegetables.*—1. *Grape* (*Vitis vitifera*). The grape vine is one of the oldest of our cultivated plants, the main object of its culture having been, as now, to obtain from its juice a wine, which is the staple drink[1] of many millions of men. Like the wheat plant, its native habitat is unknown, and if neglected by man it degenerates. The limits to the culture of the vine in Europe are (Boussingault) where the mean temperature is from 50° to 52°, and where the mean heat of the summer is from 65° to 67°. Ripe grape juice, when expressed, is found to contain grape sugar, gluten and albumen, tartaric acid and potassa, a volatile oil, tannin, colouring matter, and water. Of dried grapes or raisins there are two kinds, the smaller or Corinthian currants, and the larger, of which there are many varieties.

c. *Sugar-yielding Vegetables.*—1. *Sugar-Cane* (*Saccharum officinale*). Its ripe juice consists of sugar, gum, acetic acid, malic acid, potassa, &c. This is boiled with lime, and then evaporated, the raw or muscovado sugar being obtained. The impurities are got rid of by means of refining, and crystallized sugar is the result. A portion of the sugar, however, will not crystallize, and constitutes the tenacious fluid called molasses or treacle. Cane sugar is now enormously consumed as an article of food. Although the dietetical action of sugar is unquestionably mainly to supply carbon for the purpose of respiration, it would also certainly seem to be able to afford fat. During the time of taking the crop in Jamaica, and when the labour is severe, the work-people use it liberally, and "every negro on the plantations, and every animal, even the dogs, grow fat."

a. Subsection of Sugar-yielding Vegetables. Fruits.—1. *Apple* (*Pyrus Malus*). A great many varieties of apples are cultivated, some of which, perhaps, differ a little in the relative proportion of their constituents. Their average composition is probably about 85 or 86 per cent. of water, 10 of saccharine (a portion of this, however, gum), rather more than one of malic acid, and a small quantity (perhaps not yet ascertained) of albuminous principles. They likewise contain a volatile matter, salts, and some tannin, as is indicated by the black colour they strike if cut with a steel knife. In many parts of France and the States of America, apples constitute an important article of food, but unless the amount of albuminous matter is greater than is known, they can only afford carbon to the system. 2. *Pears, &c.* (*Pyrus communis*). The pear does not materially differ in chemical constitution from the apple. The varieties of smell and taste probably are dependent upon a little peculiar volatile oil. A jargonelle yields one-fifth of albuminous matter. Plums, cherries, oranges, &c., consist mainly of water, with a small portion of saccharine, a still less of albuminous principles, malic and other acids, and various essential oils upon which their flavours and colours depend. 3. *Gooseberries, Currants, &c.* (*Ribes*). All these are tolerably nutritious, containing nearly seven per cent. of saccharine proximate principles, and almost one of albuminous.

d. *Products obtained by art from Sugar-yielding Vegetables.* With the exception of cane sugar, the products artificially obtained from the preceding sugar-yielding plants are in this country of far more dietetical consequence than the original structures of the vegetables themselves. The theory of the preparation of their products will be found in Section III. In this place their chemical composition, their physiological action, and their more important varieties, are described. 1. *Wine.* This beverage consists of grape-juice, the sugar of which has, by the action of its albumen, been made to ferment, to evolve carbonic acid, and to leave behind alcohol. As grape-juice essentially contains tartaric acid, so does wine essentially contain it, and this possession of tartaric acid is in fact the distinguishing mark of wine from other fermented drinks. Wine also contains a volatile oil, which seems to vary much in grapes grown in different climates and on different soils, and this oil is technically called its *bouquet.* Wine also contains a colouring matter, often tannin, free acids, &c. *Wines may be arranged into three classes.*—*a.* Thoroughly fermented wines, in which all the sugar, or nearly all of it, is converted into alcohol and carbonic acid, and the latter product allowed to escape into the air. This class includes port, sherry, burgundy (still), claret, hock (which, however, contains an excess of tartaric or other acid), madeira, and the like. *b.* Wines not thoroughly fermented, and in which a considerable portion of the sugar remains as undecomposed sugar; as tent, tokay, frontignac, Candian wine, &c. *c.* Wines thoroughly fermented, but in which some of the carbonic acid is not allowed to escape into the air, but retained in the liquid, as in champagne and sparkling moselle. The proportion of alcohol in different kinds of wine is variable both in the different kinds of wine and in different years. Port usually contains about 25 per cent., claret about 15, and hock and champagne about 12 per cent. In France, however (where the chemical changes that take place in wine-making are thoroughly understood), if the juice of the grape contain too little sugar, beetroot sugar is added, and thus the average strength of French wine is kept up. The great dietetical use of wine, in a mere animal point of view, is to supply carbon for the purpose of preserving the animal heat, and it will be observed that alcoholic compounds are more permanent than most other saccharine or oleaginous matters, and less bulky than these. The action of wine upon the nervous system is also an important one, but one that need not here be entered into. An average yield of wine per acre in France is 170·9 gallons. 2. *Cider and Perry.* These are produced by converting the sugar of apple and pear juice into alcohol. This is effected by bruising them, and then mixing up in one pulp the saccharine and albuminous proximate principles. See CIDER. They both, however, differ from wine in containing malic instead of tartaric acid. Besides alcohol, malic acid, and water, cider and perry contain volatile oil, colouring matter, &c. The physiological action of these beverages is probably identical with that of wine, but malic acid fermented drinks are not so much relished as tartaric acid ones. Cider and perry contain from 8 to 9 per cent. of alcohol. 3. *Beer, Ale, and Porter.* These consist of solutions of the sugar of malt, which has been converted by fermentation into alcohol. They also contain the soluble principles of malt, and for long have been flavoured

[1] It is not perhaps sufficiently borne in mind that all articles of food approach more or less to the liquid form, and in this respect only differ from one another in the proportion of water which they contain. And this difference is by no means so great as is generally supposed. Butcher meat may be put down generally as containing about 75 per cent. of water, and beer 95 per cent., turnips nearly 90, &c. &c.

with infusion of hops. When coloured black or dark brown by means of charred malt, porter is obtained; when not so coloured, the strong kind constitutes ale, and the weaker beer. All malt fermented liquors differ from wine and cider in containing neither tartaric nor malic acids. London porter contains on an average about 4 per cent. of alcohol; stout, nearly 7; ale, perhaps nearly the same; and beer, 2 more or less. Beer that cannot be distinguished from the above is made by employing common sugar instead of sugar of malt. The physiological action of malt liquor is identical with that of wine and cider. (See BREWING.) 4. *British Wines*. These are the fermented juices of native fruits, to which, as they seldom contain enough sugar to afford the requisite amount of alcohol, sugar is generally artificially added. Most of our fruits contain malic acid, and therefore domestic wines resemble cider; but if argol be added during the fermentation, they then become analogous to grape wine. The demand for them not being, at least openly (for a great deal of supposed continental wine is of home origin), very great, they are sold at a high profit, but they might be produced nearly as cheap as cider. Their physiological action is the same as that of other fermented drinks. 5. *Alcohol and spirituous drinks*. Alcohol evaporates at 173°, while the boiling point of water is 212°. Hence the alcohol can be separated from any of the wines, ciders, or malt liquors, by a little skilful application of heat, and then condensed in proper vessels. This separated alcohol can also be freed from essential oils and other impurities; and when so freed and mixed with one-half of water, it constitutes proof-spirit, which has a specific gravity of ·920. Proof-spirit, however, is not used dietetically, but several varieties of it either naturally or artificially flavoured are extensively consumed. The most important of these are—a. *Brandy*. When wine is distilled, there comes out along with the alcohol a quantity of water, and of the flavouring matter of the wine. This is brandy. It contains 53 per cent. of alcohol. A fictitious brandy is made from cider, malt, and from fermented potatoes, the latter constituting British brandy. b. *Rum and Whisky*. These are the distilled spirits of the fermented juice of the sugar cane and of malt (or *wash* as the distiller calls it). Both these are the strength of 11 overproof, sometimes (as always in the case of newly-imported rum) much more; and the physiological action of all of them is to supply carbon to the system. They perhaps contain the carbon in far too concentrated a form for actual use until diluted. They are also powerful stimulants upon the nervous system, this action being probably the result of their carbon-supplying properties. c. *Liqueurs*. Among these may be noticed—gin, which is spirit flavoured with sugar, and in the better kinds juniper berries, but in the inferior oil of turpentine; curaçoa, which is a solution in alcohol of sugar and peach-stones, or other analogous stone fruits, which undergo decomposition with some of the water present, and form a little prussic acid; crême d'absynthe, which is essentially a solution of wormwood in alcohol, sugar, and water. The physiological action of liqueurs is essentially the same as that of spirits. d. *Vinegar*. This is a diluted solution of acetic acid, generally obtained by the farther fermentation of alcohol, but sometimes now by the destructive distillation of wood. Vinegar, properly speaking, is soured wine or ale (alegar), but in practice a solution of sugar is employed to prepare commercial vinegar. This first becomes a solution of alcohol, and then, by obtaining more oxygen, a solution of vinegar. At sea, and in many parts of the continent, vinegar (or sour krout) is found very useful as affording a supply of carbon. It has probably also another action; for a certain supply of vegetable acids seems essential for the long-continued preservation of health. (This subject will be noticed in Section V.) In this country it is chiefly valued for its antiseptic properties.

e. *Leguminous Plants*. The leguminous plants used as food in this country agree in their seeds being when ripe exceedingly nutritious, and also in affording an agreeable although less nutritive food when immature. 1. *Bean* (*Vicia faba*). The ripened seed of the bean is scarcely ever now avowedly used as human food, although it is a very common practice among millers to mix bean-flour with that of wheat. Bean-meal is extremely nutritious, containing 22 per cent. of albuminous proximate principles, 45 of saccharine, and about 3 of oleaginous. A bushel of good beans weighs 65 lb. Immature beans contain much more water and less albuminous matter. 2. *Pea* (*Pisum sativum*). Ripe peas ground into meal, and baked with water or milk, were formerly a very common article of food in Scotland, but peas bread or bannocks are now almost entirely confined to Selkirkshire and a few other localities. Ripe peas are extremely nutritious, containing 20 per cent. of albuminous proximate principles, 55 of saccharine ones, and 2 of oleaginous. They are much used for soups, and very extensively and very beneficially in the royal navy along with fat pork. In this case, contrary to the vulgar opinion, the peas afford the nitrogenous (or what is incorrectly called *the* nutritious matter, *par excellence*), and the flesh the carboniferous matter. Beans and peas, perhaps, contain somewhat less phosphates than the cereal grains. 3. *French Beans* (*Phaseolus vulgaris*). This, the kidney bean, and another variety, the scarlet, are much cultivated abroad for their ripe seeds, which are very nutritious, but in this country their pods before they are ripe are eaten. They probably contain a very small quantity of *salts*.

f. *Brassicacious Vegetables*. All the edible members of the cabbage family are wholesome articles of diet, and nutritious, considering the very large proportion of watery fluid which they contain; inasmuch as they contain an admixture of saccharine, oleaginous, and albuminous proximate principles. They generally contain a large proportion of sulphur, and, when boiled, some of this usually combines with some hydrogen, sulphuretted hydrogen being formed, and thus give rise to the disagreeable smell of water in which cabbage, &c. has been boiled. 1. *Cabbage* (*Brassica*, various kinds of). Under this head may be comprehended the kinds used for their leaves, kail, hearting cabbage, savoys, and Brussels sprouts, all of which are merely modifications of the same original stock. They contain about 92 per cent. of water, some albuminous principles, some saccharine, and a considerable quantity of oleaginous. Their ash is usually great, and contains a good deal of sulphur, chlorine, phosphorus, soda, potassa, and lime. If cabbage be sliced and pressed, its saccharine principles become converted into lactic acid, and sour krout is produced. It is a nutritious, and, as will appear in Section V., a wholesome winter dish, but it is little used in this country. *Cauliflower*. The flower of this species of cabbage is the part used. It is remarkable for containing an immense amount of albuminous matter. 2. *Turnips* (*Brassica rapa*). A turnip contains about 89 per cent. of water, 7 of saccharine principles, less than 1 of albuminous, and about $\frac{1}{5}$th of oil. Its ash is rich in phosphorus. Sea-kale and other vegetables of a somewhat analogous nature are omitted, they being only used on a small scale, and there being no accurate analyses of them.

g. *Root Crops*.—1. *Potato* (*Solanum tuberosum*). It is only in popular language that the potato can be called a root. It is a tubercle or tuber attached to the root and subterranean stem. A well-grown potato contains about 75 per cent. of water, nearly 20 of saccharine compounds, about $1\frac{1}{2}$ of albuminous, and a small quantity of oleaginous. Its ash, which constitutes on an average at least 1 per cent., contains a very large quantity of potassa, and a considerable amount of phosphorus and sulphur. Potatoes have also been stated to contain citric acid. Potatoes are a nutritious article of food, and capable alone of maintaining life; but their saccharine principles are so much in excess that they ought to be eaten along with articles of food abounding in albuminous and oleaginous principles. It may be here mentioned that pigs fed upon potatoes only become fat, and acquire more fat than the oil of the potatoes can be expected to afford. This is a strong reason for admitting that saccharine proximate principles can be deoxidated in the animal economy, and deposited as oleaginous. 2. *Beet* (*Beta vulgaris*). The white beet, or mangold-wurzel, is seldom grown for human food, and is not palatable; but the red kind is a common article of diet. This contains about 2 per cent. of albuminous compounds; the amount of oily matter has not yet been ascertained, but the saccharine proximate principles amount to the very large proportion of 15 per cent. For the last-mentioned cause beet (a white variety) is much grown in France and Belgium, for the purpose of extracting sugar from it. Did the excise regulations permit it, it is calculated that sugar might be produced from beet by the farmer of this country, and sold with a profit at $2\frac{1}{2}$d. a pound. If desired, too, all the fermented and distilled drinks of this country might be made from beet sugar in place of barley and other corn. The ash of beet consists mainly of potassa, but it also has something like 10 per cent. of silica. It also contains a considerable portion of other alkalies and alkaline earths, and very little acid. 3. *Carrot* (*Daucus carota*). The root of the carrot contains 80 per cent. of water, about 18 of saccharine proximate principles, 1 of albuminous, and a little oil. It has also a volatile oil, and some malic acid. Its ash is considerable, and has much potassa and common salt. 4. *Parsnip* (*Pastinaca sativa*). This is a very nutritious root, as it contains 18 per cent. of saccharine principles, and more than 2 of albuminous. The amount of its oleaginous contents and of its ash do not seem to have been ascertained. Owing to its large quantity of sugar it is sometimes fermented; and from this liquid a spirit is also distilled. 5. *Girasole*, vulgarly *Jerusalem Artichoke* (*Helianthus tuberosus*). The tubers contain 77 per cent. of water, 18 of saccharine proximate principles, about 1 of albuminous, and some fat. It has also some citric acid. The ash is pretty considerable. Skirret, scorzonera, and some other roots now little used as food, are omitted. h. *Alliaceous vegetables*. These plants are extensively employed as food in many continental states, but are in this country principally used as flavouring agents. They contain albuminous and saccharine matter (probably in very considerable quantity), and a peculiar volatile oil to which they owe their flavour and pungency. This oil appears to relieve the oppression of very hot weather. They contain citric acid, and their ash is rich in

sulphur and phosphorus. The most important of them are the onion and the leek. In this country garlic, rocambole, eschallots, and chives, are little grown. i. *Asparaginous vegetables.* Asparagus, artichoke, and spinach are nearly entirely composed of water, but they have some saccharine principles, and also peculiar ones to which they owe their characteristic flavour. They probably contain acids. k. *Salad vegetables.* Lettuce, celery, endive, &c., perhaps contain a larger proportion of nutrient matter than is generally thought, as they constitute an important article of diet in most southern continental countries. They probably are mainly useful in affording carbon, and thus allowing the eater to dispense with an equivalent of fermented drink. But there does not appear to be any recent analysis of them. l. *Nuts.* Nuts are little employed as an article of diet in this country, but in many continental states they form staple articles of food, and are very nutritious. The sweet acorns, the seeds of the ilex, are chiefly those eaten, and contain 47 per cent. of saccharine proximate principles, 15 of albuminous, and 3 of oleaginous. The nuts chiefly eaten in this country are the hazel, the walnut, and the chestnut. m. *Oil-producing vegetables.*—1. *Olive tree* (*Olea europea*). The expressed oil of the olive is the only vegetable oil that is dietetically used in an isolated form in this country. The oil is imported from the south of France and Italy, and also, but of inferior quality, from Spain. It consists of oleine and margarine, the former being most abundant. Its alimentary action is to supply carbon. On the Continent it is extensively used with bread and a great many dishes, but in this country its use is confined for the most part to salads. In many parts of Italy and Greece ripe olives are salted, and form a staple food. Unripe olives pickled in an aromatic solution of salt are imported as a luxury to this country. n. *Beverage vegetables.*—1. *Tea* (*Thea viridis* and *Thea Bohea*). The prevalent opinion is that black tea is the produce of *T. Bohea*, and green of the *T. viridis*, and that the different varieties of each sort depend upon modes of preparation. Notwithstanding the immense consumption of infusion of tea, and the very important place that it has taken among the dietetics of this country, our knowledge of its chemical constitution, and consequently of its physiological action, is by no means definite. Tea certainly would appear to contain at least a third of an astringent principle, about 6 per cent. of saccharine proximate principles in the form of gum, 2 or 2½ of volatile matter, upon which its fragrance &c. depend, and 6 of albuminous matter, including about a half per cent. of the peculiar principle called *theine*. From 45 to 50 per cent. are cellulose or lignin. Even from this very imperfect analysis it will be apparent that an infusion of tea is a nutritious agent, affording to the system saccharine and albuminous, and perhaps oleaginous proximate principles. Daily experience proves this; for many people who lead a sedentary life, *i. e.* who require not very rapid supplies of food, particularly of nitrogen and carbon, keep up their flesh and strength upon a diet of which tea is the principal or a principal part. Indeed a pint of tea of ordinary strength will contain nearly 1 per cent. of albuminous and saccharine compounds, which is not much less than weak soup has. But the principle *theine* has perhaps some nutritive action with which we are not yet familiar; and this probability is increased when we consider that both coffee and chocolate contain it. Liebig's conjecture is that it serves to form bile; but this hypothesis is not likely to find much favour with those English physiologists who maintain that bile is an excretion. The action of tea upon the nervous system will be noticed in Section V. Green tea differs from black in containing more volatile oil and more tannin, although this latter is denied. The different commercial kinds of black and green teas differ from one another in their mode of preparation, and in the consequent amount of volatile matter &c. they possess. The following are the most important of them. a. *Varieties of Black Tea.* a. *Bohea.* This, and particularly the kind called Canton bohea, is the refuse and large and coarse leaves of the other black kinds, and is often employed to adulterate other sorts. b. *Congou* is the full-developed leaf, and is the kind generally used in this country. c. *Souchong* is another full-developed black-tea leaf, and is distinguished from the previous by the greener colour of its infusion. d. *Pekoe* is prepared from the undeveloped or unexpanded leaf-bud of the black tea. It is considered the best kind, but is difficult to procure unmixed. b. *Varieties of Green Teas.*—a. *Twankay* is a common kind not much used. It consists of the expanded leaf. b. *Hyson* consists of the expanded leaf, but it is said to be of the second or third crop. It is the green tea usually drank in this country. c. *Gunpowder* consists of the unopened buds of the spring crop of the green-tea plant, and, like the pekoe, it is the best of its class. According to Mr Fortune the green tea is a leaf dyed in the process of drying by a mixture of indigo, turmeric, and gypsum. 2. *Coffee* (*Coffea arabica*)—the berries of the coffee plant with the husk removed. The following analysis of coffee is by Payen:—Cellulose, 34; water, 12; fat, 13; dextrine and other saccharine principles, 15; caseine, legumine, 10; nitrogenous substance, 3; caffeine (theine), 8; oil, 3; ash, 6; other matters, 3. According to this analysis coffee is an extremely nutritious substance. The roasting process, preparatory to its infusion, has no effect upon its nutritive properties, but merely communicates the characteristic flavour and smell. Of the several kinds, the Mocha coffee is the most esteemed. 3. *Chicory* (*Chicorium Intybus*). The roasted root of this plant when ground is either mixed with coffee or used alone. We have no recent analysis of it, but we know that it contains a good deal of saccharine principles, and a bitter extractive matter upon which its flavour seems to depend. Experience also teaches that it is perfectly wholesome, and to many people it forms a very palatable beverage. (See CHICORY.) 4. *Chocolate* (*Theobroma Cacao*). The kernels of the seeds of this plant contain more than 50 per cent. of oleaginous matter, nearly 17 of albuminous, and 18 of saccharine principles. It also possesses a principle called *theobromine*, analogous to theine. Chocolate is consequently one of the most nutritious articles of food which we possess; but its large quantity of oil makes it indigestible to many persons. It is now advantageously substituted in the navy to supply carbon, in place of some of the large quantity of rum formerly allowed. There are several modes of preparing the seeds. The roasted and ground kernels, made into a paste with vanilla, &c., and dried in mould, constitute chocolate proper. In order to diffuse it among boiling water it requires the somewhat tedious process of *milling*. A patent preparation (there are two or three varieties of it), Fry's chocolate, can be dissolved in water at once. The kernels of the roasted seeds constitute nib cocoa of the shops. The entire roasted seeds of both kernels and their husks ground down, make cocoa.

B. *The varieties of Animals used as Human Aliment.*

a. *Quadrupeds.* The various proximate principles that enter into the several structures of the quadrupeds used as human food are enumerated at p. 758. Herbivorous quadrupeds may almost always be eaten without danger. Sometimes, however, articles of food derived from quadrupeds do become poisonous, or at any rate injurious. The following have occasionally been noticed to do so. a. *Bacon*, and other cured or salted meat. There are several instances on record of bacon having become somewhat poisonous, although it has never perhaps destroyed life. It would appear that decomposition ensues, and that kreatine or some analogous compound combines with the salt or with the nitre used in the preserving, and that a deleterious compound is thereby produced. Such an accident, however, is extremely rare. b. *Sausage poison.* Sausages, at least in Germany, have pretty often acquired poisonous properties, and have occasionally destroyed life. This has generally occurred in long-kept sausages, and usually in the spring season. The decomposing sausages become acid and soft, and acquire a nauseous taste and smell. When, however, they begin to emit sulphuretted hydrogen their poisonous property is lost, but until then they are stated to be very deleterious. Of the nature of this sausage poison nothing is known. c. *Cheese.* Cheese has occasionally in Germany, and perhaps also in Cheshire, acquired poisonous properties, owing probably to some modification of an acetous fermentation. These very rare, and sometimes perhaps not very well-founded, cases of poisoning prove with what impunity in general food derived from quadrupeds may be used. 1. *The Ox* (*Bos taurus*). The flesh of the mature ox, or beef, constitutes in this country by far the greatest proportion of animal food that is eaten. That of the ox proper is most esteemed, next that of a heifer that has never been a milch cow, next that of a milch cow, and lastly that of a bull; it may be, however, that part of the dislike felt to the beef of cows and bulls is attributable to these animals not generally being slaughtered until they become so old that the cartilaginous matter dispersed among the muscles is tending to become osseous, and that other earthy deposits are being formed, the result of which is that the meat becomes ill-flavoured and tough. Occasionally some of the small breeds, as the Shetlands, are kept on grass for five years or longer, but by far the greater proportion of oxen are now slaughtered when they are in their third year, and some, as most shorthorns, before they are two years old. In this latter case, and indeed practically in almost all cases, they are now fattened more or less upon turnips, often with the addition of a little oil-cake. And it is quite certain that oxen put up to fatten in hammels in October, and slaughtered in a few months, *i. e.* entirely fattened without grass, afford as good beef as those altogether or entirely (as in the old way) fattened upon grass; and this is exactly in accordance with what our knowledge of the proximate principles of the food of oxen would teach us. The beef of the different breeds varies a little. That of the Shetland is perhaps the most compact, or finest grained as it is called. Next to the Shetland beef, that of the West Highland breed, and of the Welsh (the latter, however, rarely well enough fattened), is probably best; next that of the Galloways, Angus, and those of the Devon breed; and lastly the Herefords and shorthorns. But the last, or shorthorns, will always, in arable districts, form the preponder-

ating breed, from the readiness with which they become maturely fat at an early age upon turnips. Every hundred pounds of a fat ox give of butcher meat (including bones) 57·7 per cent.; tallow, 8·0 per cent.; hide, 5·5 per cent.; entrails and offal, 28·8 per cent. Some of the larger breeds grow to an immense size, attaining a weight of a hundred stones and more; but the beef of such is not in such estimation as that of the smaller kinds. Shetland oxen perhaps do not average twenty stones. The flesh of young bovine animals, which is known as *veal*, differs from beef in containing less fibrine, and in most parts of it containing considerably more gelatine. It has also an appreciable quantity more water, and the meat is whiter owing to the portion of blood left among its fibres containing a smaller quantity of red globules. About London a calf is usually slaughtered when ten weeks old, when it will weigh as many imperial stones of veal (the offal being omitted). As gelatine is longer in being converted into chyme than fibrine, veal is less readily digested than beef; and the same may be said of the flesh of most young animals. 2. *The Sheep* (*Ovis aries*). Mutton differs probably in only some trifling peculiarities from beef. Among these is that its retained blood contains fewer globules, and is therefore not so dark-coloured. Sheep are occasionally kept for four or five years, and occasionally longer, before they are considered fit for the butcher; but the great majority of those sent to the market (and their meat cannot be distinguished from older ones) are not much more than two years old. By far the best mutton is that of the wether, next that of a young ewe, then of an old ewe, and the worst of all that of a tup. The offal of a sheep is to the part saleable as food as one to three. Perhaps 120 pounds may be stated as the weight of an ordinary sheep's carcase. Of the several breeds, the Leicester sheep is the largest, and the one that comes earliest to maturity; but its flesh contains a large, and indeed excessive, quantity of oleaginous matter, mixed with the muscular fibre; and this renders the meat heavy and unpalatable. But as Leicester sheep soon become fat, and at a very early age, and attain, moreover, a very large size, the breed is a favourite one with the farmers. The Cheviot and Southdown (the two breeds are dietetically analogous) are smaller than the preceding, have darker meat, less fat, and are in every respect superior. The black-faced and Welsh varieties are still smaller, have less fat, and their flesh is much darker. Their flesh, too, has a particular, and, to most people, a very agreeable, flavour, owing probably to some peculiar oil in the fat. If well fed, they are, contrary to a popular opinion, in perfection when about two years of age. The flesh of lambs differs from that of sheep in containing more gelatine and water, and less fibrine. It is therefore less easy of digestion. 3. *Goat and Kid* (*Capra hyrcus*). Formerly goat-flesh was much used, and in modern Italy and the Peninsula it still is; but in this country the use of goat-flesh is confined to a few localities in the Highlands and in Wales. Kid-flesh is probably very analogous to that of lamb. 4. *Deer* (*Cervus*). Three kinds of venison are used as food in this country—that of the fallow-deer, which is considered the best; that of the larger stag; and that of the roebuck. All venison is darker than any other meat, owing, probably, to its retaining more blood corpuscles; and in flavour it resembles that of black-faced sheep. Fallow-deer and stags are considered to be in perfection at four years of age, and are not good food for three or four months after August. Venison has less fat than even black-faced mutton. 5. *Hog* (*Sus scrofa*). Of all quadrupeds whose flesh is employed as food, the hog is perhaps the most profitable. In the course of a twelvemonth it attains a large size (often 20 stones, or indeed much more). From its sedentary habits it wastes far less flesh, and consumes less of the carbon of its food, than any other of our domesticated animals, and has likewise a far less proportion of offal to useable meat than any other animal. Thus a pig that, when alive, weighed 199 lb., yielded a clean carcase that weighed 139 lb. (*Stephens.*) A well-fed hog, too, contains a large proportion of oleaginous matter separate from its muscles; and its physiological action when employed as food, in the form of bacon, is mainly to supply carbon. This fat also, when separated from its cellular tissues, differs from most other animal fats in containing more oleine, and is hence much used in cooking. For the same reason, the flesh of hogs when salted is less dry than that of any other salted meat. Fresh pork contains about 19 per cent. of albuminous matter, 1½ of salts, and more than 78 of water. 6. *Hare* (*Lepus timidus*). From its very active habits, the hare consumes the carbon of its food, and hence deposits no fat. For some reason or other, partly from its never having been bled, the blood is retained in great quantities among the muscles, and this makes the flesh very dark-coloured, but at the same time renders its infusion in soup very nutritious. Hares are not good food from February to August, that being their breeding-time. Hares weigh from 3 or 4 lb. to 10 or 12. The Alpine hare (*Lepus variabilis*) is smaller than the common hare, from which it may at once be known by its shorter ears and white fur in winter; and the colour of its flesh is intermediate between that of the common hare and the rabbit. 7. *Rabbit* (*Lepus cuniculus*). The wild rabbit, like the hare, has no fat, and its flesh is much whiter. It is used almost all the year round. A common weight is about 3 lb. Tame rabbits grow to a much larger size, and often contain fat. Of hares and rabbits, the eatable portion amounts perhaps to 50 per cent. of the original weight of the animal.

b. *Birds*. In birds that use active flight, or have been intended to do so, as partridges, fowls, &c., the pectoral muscles are whiter and drier, and are considered better than those which move the legs; but the reverse of this is usually held to be the case in aquatic birds, as ducks, which use principally the leg muscles. The cooking of the entrails of a woodcock, and the inducing in the goose an enlarged and diseased state of the liver, are also practices, but surely not very commendable ones, of epicures. 1. *Fowl* (*Gallus domesticus*). As compared with beef, the flesh of the fowl contains a little less water, only a fraction per cent. less of albuminous matter, and a greater proportion of salts. Hence, as a flesh-forming product, fowl is more nutritious than beef, but it is deficient in oleaginous or carbon-supplying matter. 2. *Turkey* (*Meleagris gallopavo*). Young turkeys about nine months old often weigh from 15 lb. upwards. In chemical constitution and in physiological action the flesh of a turkey is probably nearly identical with that of the common fowl. There are three varieties of turkeys—the black, the white, and the mottled gray. Of these the black is the hardiest, and is also thought to yield the best food. 3. *Guinea-fowl* (*Meleagris Numida*) very much resembles the turkey in the properties of its flesh, but owing probably to its semi-wild habits, it has somewhat of a game flavour, and is used as a substitute for game when game is out of season. 4. *Peacock* (*Pavo cristatus*). The flesh of the old pea-fowl is coarse and ill-flavoured, but the young bird is palatable, though rarely used as food. 5. *Partridge* (*Perdix cinerea*). The flesh of this and the four following birds has a peculiar flavour, arising doubtless from something introduced into their system by their food. There are two kinds of partridge, the common one and the red-legged partridge. They are only used from September to February. In common with other game, partridges, when long kept, acquire a peculiar smell and bitter flavour, both probably owing to kreatine. A partridge, with its feathers and entrails, weighs generally somewhat less than 1 lb. b. *Black-cock* (*Tetrao tetrix*). This beautiful and delicate bird is in season from the 20th of August to the 10th of December. It feeds pretty much on mountain berries, heath tops, and birch tops, which probably communicate part of its peculiar flavour. A cock weighs about 1 lb. The female (called a *gray hen*) weighs about 2 lb. 7. *Pheasant* (*Phasianus colchicus*). Except in its larger size, this bird resembles dietetically the partridge. It is in season from the 1st of October to the 2d of February. 8. *Grouse* and *Ptarmigan* (*Lagopus scoticus* and *vulgaris*). The red and white grouse live very much upon heather, which communicates to their flesh its peculiar flavour. Each weighs when killed about 1¼ lb. The capercailzie, *Tetrao urogallus*, (sometimes called woodland grouse) is perhaps extinct in the country, but sometimes appears in the market. One will weigh from 7 to 12 lb. 9. *Quail* (*Coturnix vulgaris*). This small bird resembles the patridge in flavour, and is in season from May to October. 10. *Duck* (*Anas boschus*). The flesh of aquatic birds is still darker than that of the game birds noticed above, this being owing to their muscles retaining more blood. Also, when in condition, they have a good deal of fat underneath their skins. As their lean is quite as nutritious as that of fowls and game, and as they contain this oleaginous matter in addition, they are more valuable as nutritive agents. The duck is in best condition in autumn; but ducklings are sold earlier. A common weight of a full-grown tame duck is 2½ or 3 lb. The wild duck is smaller. Wild ducks taken near the sea have usually a fishy taste, derived from their food. The *widgeon* (*Anas penelope*) is a species of wild duck. Its flesh is dark and dry, and is by many esteemed, but it is often fishy. Its average weight is 1½ lb. The *teal* (*Anas crecca*) is a still smaller kind of wild duck, the flesh of which is thought much superior to that of the widgeon. It is below 1 lb. in weight. Widgeons and teal are fat and in season at the end of the year. 11. *Goose* (*Anser palustris*). In common with that of most aquatic birds, the flesh of the goose seems to contain some peculiar matter, perhaps oleaginous (although this is quite contrary to what happens in birds), but the nature of which is unknown. A goose weighs (without feathers and offal) 6 lb. and upwards. The *Solan goose*, as it is called (*Pelicanus bassanus*), is really a pelican. It is caught on the Bass rock in the Firth of Forth, and in the Hebrides. It is salted and smoked. The flavour is very fishy. One weighs about 7 lb. A very analogous bird is the *puffin*, which is also salted, but, like the solan goose, it has a very fishy taste, and its use as food is almost wholly confined to the poor. They are chiefly captured for the sake of their feathers. 12. *Pigeon* (*Columba*). The flesh of the different kinds of pigeon, and of the lark (a bird be-

longing to a different natural family), is intermediate between that of poultry and game both in colour and flavour. As rich in albuminous matter it probably ranks high. The flesh of the pigeon indeed contains $21\frac{1}{2}$ per cent. of albuminous matter, and is therefore, as a flesh-forming article of diet, not only more nutritious than beef, but indeed more so than any article of animal food. Only the young (before they fly) of the domesticated pigeon are used at table. 13. *Woodcock* (*Scolopax rusticola*). This and the following four birds are waders, and their food consists of aquatic insects, small fishes, and the like. Their flesh is considered delicate; but it has not been subjected to analysis. A woodcock weighs 12 oz., and is in season from October to March. The common snipe, jack-snipe, plover, and landrail, are only considered fit for table when fat, which is at the beginning of winter, and during that season. The *bustard*, of the family of CURSORES, is now nearly or altogether extinct in this country. A few are sometimes yet caught in France, and sell very high. 14. *Rook* (*Corvus frugilegus*). The only predacious bird that is used for food is the young rook, and this but to a small extent. Its flavour is peculiar, and to many persons far from agreeable. 15. *Eggs*. The eggs of birds are a rather important article of diet. They resemble one another very much in composition and in their physiological action, and the several kinds probably do not materially differ from each other, save in containing some small amount of a peculiar volatile oil. A bird's egg essentially consists of shell, a membrane lining it, a white or albumen, and a yolk. Besides these, the yolk contains a membrane, the chalaza, which, as a dietetical agent, may be altogether overlooked. The shell is composed of a little animal matter, and phosphates of lime and magnesia, with 97 per cent. of carbonate of lime. The white of a common hen's egg is composed of water, 8·0; mucus, 4·5; albumen, 15·5. It also contains about 4 per cent. of inorganic ingredients (omitted in this analysis). These are sulphur, phosphorus, chlorine, potassa, soda, lime, and magnesia. The yolk contains, water, 53·73; albumen, 17·47; oil, 28·75. This oil contains 90 per cent. of oleine and only 10 of stearine. There is also a colouring principle, and nearly 6 per cent. of ash, the composition of which is much the same as that of the white, but it contains a greater proportion of phosphorus and (according to Liebig) iron. From these analyses it will be seen that eggs are extremely nutritious, being rich in albuminous and oleaginous compounds. The eggs of different birds probably contain a little volatile oil peculiar to each species, upon which their characteristic flavour depends.

c. *Reptiles*. Although several species of reptiles are used as food in other countries, the only one ever so employed in this is green turtle (*Testudo myas*), which is now regularly imported from the West Indies. It is particularly valued for a green gelatinous substance, commonly but erroneously termed its *fat*. In this country turtle is almost exclusively made into soup, but in the West Indies it is made into steak, &c. Turtle contains much gelatine and little fibrine. It probably, in a nutritive point of view, resembles, but is inferior to, veal. Vipers were formerly used in this country as a remedy for consumption, and a receipt for making viper-broth was once contained in the pharmacopœia. A species of frog is used as food on the Continent, but it is perhaps never eaten in this country. Indeed here the animal is rare.

d. *Fishes*. Fish constitute an important and economic article of food. The result of various analyses of fishes is to indicate that their muscles contain nearly but not quite as much of albuminous proximate principles as the flesh of quadrupeds, and fully as much of saline ingredients. Hence as flesh-producing articles of diet they are nearly equal to beef, &c. Some of the fishes, as trout, salmon, &c., contain also much oleaginous matter; but in others, as cod, haddock, &c., the oil is entirely confined to the liver. This latter class of fishes does not afford so much carbon to the system for respiratory purposes. Fish are in season before spawning, and for some time after they have spawned they are not good; but as most fish resort to the deep water after spawning, they are seldom caught in this state. Not only is recently-spawned fish flabby and tasteless, but it is sometimes positively unwholesome. Fish in tropical countries have sometimes proved poisonous, probably from the nature of their food. It is, however, certain that in this country no fish in season is unwholesome, although the barbel and the pike have for long been considered injurious. The following is a short account of the various species of fish commonly employed as food in Great Britain. 1. *Lamprey* (*Petromyzon marinus*). The sea lamprey is an oily and fibrous fish, whose bones are composed of cartilage (having no osseous matter). It is about two feet long. It ascends the rivers from the sea to spawn in spring, and is then in season. It is considered a great delicacy. It is not a common fish in Britain, only occurring, at least abundantly, in some southern rivers, but in many European rivers they occur so plentifully that they are salted and barrelled. There is also another smaller species. 2. *Dog-fish* (*Scyllium canicula*). This is a member of the shark family, and is very often caught in the herring-nets on the Scottish coasts. It is an oily and fibrous fish, and has a cartilaginous skeleton. Dog-fish are dried and used as winter food by the poorer people of the northern coasts. From their composition they are very nutritious, but they have a strong, disagreeable taste. 3. *Skate* (*Raia batis*). The larger skate live in deep water, and are seldom caught; but even the smaller ones in the shallows have been known to weigh 200 lb. Those commonly taken weigh perhaps from 6 to 20 lb. The flesh, from its containing oil, is very nutritious. Skate is in season from July till nearly the end of winter. 4. *Thornback* (*Raia clavata*) may be known from the skate by having spines upon the back, and it is smaller, seldom exceeding two feet in length. The young ones are called maids. The flesh resembles that of skate. 5. *Sturgeon* (*Acipenser sturio*). This fish sometimes ascends our rivers, and gets entangled in the salmon-nets. These generally are from 4 to 8 feet long (sometimes longer), and occasionally weigh 300 lb. Sturgeon is in season in winter and spring. The skeleton is gelatinous. Its flesh nearly resembles the taste of veal, and is much esteemed. The salted roe of the sturgeon constitutes *caviare*. It is sometimes imported to this country from Russia. 6. *Salmon* (*Salmo salar*). The salmon begins to enter the rivers for the purpose of spawning in autumn, and the parent fish return to the sea during the months of February, March, and April. The hatched young ones follow in April, May, and June. The salmon is in greatest perfection when ascending the rivers; but there is such a demand for salmon, that it has been found necessary to make enactments, rendering the taking of salmon legal only in certain seasons. All salmon fisheries north of the Tweed open on the 1st of February, and close on the 14th of September. The Tweed fishing opens on the 15th of February, and closes the 15th of October. As the spawn is deposited from October to February, this keeps up the breed; but it is plain that some of these fish will be caught when they are not in season, being weakened by the spawning. From 6 to 10 lb. is a common weight of a salmon, though sometimes this fish attains a much greater weight. As salmon contain oleaginous principles mixed among its albuminous, it is very nutritious. A young salmon returning for the first time to its native river, and weighing from 3 to 6 lb., is a grilse. 7. *Bull trout* (*Salmo eriox*). This fish is not in much esteem. Its flesh is white. 8. *Sea trout*, or *salmon trout* (*Salmo trutta*). This fish is about 18 inches long, and weighs about 3 lb. Its flesh is red, and is considered very good. Its migrations and seasons are much similar to those of the salmon. 9. *Trout* (*Salmo fario*). This well-known fish is a permanent resident in our rivers. There are several sub-varieties of it, which differ mainly in their flesh being more or less of a reddish hue; but, in general, it is nearly white. The Gillaroo trout differs from the common trout in having a very thick stomach. Trout are in season from February to August, and when full grown are about a foot long, and weigh about 1 lb. Sometimes, particularly in weirs, they attain a much larger size. The char, another variety of the salmon, only occurs in one or two lakes. 10. *Smelt* (*Osmerus eperlanus*). This little fish is generally about 8 or 9 inches long, and weighs less than $\frac{1}{2}$ lb. It is remarkable for the great transparency of its body, particularly of its head, and for a peculiar odour, which is thought to resemble that of a cucumber. It is a sea fish, but enters the estuaries to spawn, and stays there from autumn till March. It is in season in November, December, and January. 11. *Grayling* (*Salmo thymallus*) is a migrating fish, leaving the sea in the end of autumn to ascend clear rivers, for the purpose of spawning. It should be stated, that there is some doubt if it really does live in the sea. It is in best season at mid-winter. Its flesh, which is firm and white, is considered to have a very fine flavour. It weighs about as much as a trout. The above six fishes belong to the salmon family, and by some naturalists are considered species of the same genus, *Salmo*. 12. *Herring* (*Clupea harengus*). This fish is one of the most useful that approaches our shores. Immense shoals of it appear off the Shetland Islands in April, and are succeeded by a still more immense shoal in June. These shoals extend southward on the east and west coasts of Scotland, and in localities on the eastern coast of England. Their purpose in approaching the estuaries and coasts is to spawn; and, like other fish, they are then in best season. The herring contains a large quantity of oleaginous matter mixed with its albuminous principles, and is very nutritious. A herring is about a foot long, and seldom weighs quite a pound. Herrings are extensively employed both pickled and dried. 13. *Pilchard* (*Clupea pilchardus*) very much resembles the herring, but has a rounder body and no teeth. It appears in vast shoals off the Cornish coast in July, and is occasionally caught in more northern seas. The flesh contains more oil than that of the herring. In Cornwall, during their season, they are so extremely cheap as to be sometimes used as a manure. The sardine, which in a pickled state is imported from the Mediterranean, seems to be a small pilchard. The fry of the herring and pilchard are sold indiscriminately under the name of sprats. There is, however, a distinct small species, the *Clupea sprattus*. All these

are pickled red with cochineal or red lead, and sold as pickled anchovies. They may be distinguished by always retaining more or less of their backbone in an osseous state. 14. *Shad* (*Clupea alosa*) ascends the Severn and Thames to spawn, and is in season in July. It is in no esteem. The white bait is by many considered to be its fry, although naturalists maintain that it is a distinct species, *Clupea alba*. 15. *Anchovy* (*Clupea encrasicolus*). This little fish is abundant enough on our own coasts for our own supply, but it is imported in a pickled state from the Mediterranean. During the pickling it is boiled, and its backbone is quite dissolved. 16. *Pike* (*Esox lucius*) is a fresh-water fish that inhabits our rivers and lakes. A full-grown one weighs from five to a great many pounds, and when under 2 lb. is called a *jack*. The pike affords a very dry food, and has no oil. The sea pike or gar (*Belone vulgaris*) is pretty often caught on our coasts, but is not esteemed. Its backbone, as in the viviparous Blenny, becomes green by boiling. 17. *Carp* (*Cyprinus carpio*). This fish, before the railways conveyed salt-water fish to inland parts, was in greater esteem than it is now, or probably ever will be again in this country. It is the fish that is most commonly bred in ponds. It weighs from 3 to 20 lb. Carps are in season from April to October. Other fishes of the same family (the Cyprinidæ) all fresh-water ones, are sometimes used as food, and may be here mentioned. The barbel inhabits English rivers, and grows to two or three feet long, but it is considered very indifferent food. The little gudgeon is caught during summer in shallow streams, and is regarded as very good. The tench is perhaps the best dietetical fish of the family. It sometimes attains a weight of 4 or 5 lb., but is usually under 1 lb. It is in season from May to October. The bream is another fresh-water fish that inhabits some of our lakes and sluggish rivers. In appearance it almost resembles a flat fish. It is not much esteemed in this country, but in France it is. It spawns in July, and is in season two or three months before, but some regard it as in best season in September just after it has recovered its strength. It weighs from ½ lb. to 3 or 4 lb. The chub, the roach, and the dace are all river fish, and in little estimation. Their flesh appears to contain an excess of water which perhaps renders them insipid. Walton, however, maintained that the chub owed its bad reputation to ignorant cookery. 19. *The Cod family*. Members of this very important group afford large and most valuable supplies of food, both in a fresh and salted state. They all contain a due proportion of albuminous matter, but their muscular part has no oleaginous principle, all their oil being contained in their livers; although perhaps the milts contain a little. a. *Cod* (*Morhua vulgaris*, or, old name, *Gadus Morhua*). This, one of the most numerous of fishes, is abundant on many of our coasts, and (salted) is exported in abundance from Zetland, Iceland, and Newfoundland. It spawns in spring, and is therefore in season in the winter months, but it appears to recover from spawning sooner than almost any other fish, or at least large fish, and is good during the greater part of summer. It weighs from 6 to 20 lb., and occasionally more. Young cod, or codlings, are far more watery and insipid than the mature cod. Indeed many that are sold as such are really young coal-fish. The swimming bladders of the cod are also salted, and used as food. They consist almost entirely of gelatine. b. *Haddock* (*Morhua æglifinus*, or *Gadus æglifinus*) is much smaller than the cod, seldom being longer than 1½ ft., or weighing more than from 2 to 3 lb. Its flesh, however, is more delicate than that of the cod. Haddocks are in season from May to September. They are used fresh, slightly salted, or smoked (then called Finnan haddocks). c. *Ling* (*Molva vulgaris*, or *Gadus Molva*) is taken in considerable quantities on our northern and north-eastern coasts. It is much slenderer than the cod, and, like it, is eaten both fresh and salted. Contrary to the general opinion, it is in both ways superior to the cod. It spawns in June, and is in perfection to the end of May, and it may be known to be in season by its liver being white. It seems probable that a great many of the so-called cod sounds are ling sounds. The ling attains the same weight as the cod. Dried cod is very often sold as dried ling. d. *Tusk and Hake* (*Brosmius vulgaris*, and *Merluccius vulgaris*, or *Gadus Brosmius* and *Gadus Merluccius*). The first of these is common in the north and the other in the south. They are both caught along with ling and cod, and are about the same size. They are generally dried and salted. Another species of the same family, and of the same genus as the tusk, is the coal-fish, which in certain localities, as the Scottish islands, is extensively used. It has various names. In Scotland a young one is called a podley and an old one a sethe. Considerable quantities of cod, ling, tusk, hake, and coal-fish are salted and dried, and largely exported. It is called stock-fish; and as most of the water is expelled it is an extremely concentrated and nutritious article of diet, though not very digestible. e. *Whiting* (*Merlangus vulgaris* or *Gadus Merlangus*) is the most delicate fish of its family. It spawns from March to September, and is therefore in best season during the two first months of the year. It is however pretty good towards the end of the year. In the south of England it is frequently salted, and is there called "buck-horn." A whiting is usually about a foot long, and seldom weighs more than 1 lb. 20. *The Flat fish*. These fishes belong to the Pleuronectidæ, and are easily recognised by their flattened form, and by having both their eyes on one side. They are much esteemed for their delicate flavour. The oleaginous principles are confined to their livers, and hence they only furnish albuminous matter, but they contain (at least some of them) more than 20 per cent. of it. a. *Plaice* (*Platessa vulgaris*). This and the two following platessæ are known from the other flat fish by each jaw having a single row of obtuse teeth, a spine at the beginning of the anal fin, and a rounded tail. The body is rhomboidal, and the eyes are generally on the right side. The plaice has a smooth body, with six tubercles on its head. It is considered one of the most flabby and worst of the flat fish. It weighs from ¾ of a lb. to 3 or 4 lb. b. *Flounder* (*Platessa plesus*). The body of the flounder or fluke is smooth, and it has a band of sharp spines on the side lines and at the junction of the anal and dorsal fins with the body. It is in season from January to March, and from July to September. c. *Dab* (*Platessa Limanda*) has scales, and is rather less and thinner than the flounder. It spawns in May, and is out of season in that and the following month. d. *Holibut* (*Hippoglossus vulgaris*) may be known by its slender pointed teeth, its elongated body, and lunated tail. It is a large fish, sometimes weighing 200 lb. Its flesh is white and good, although by many not much esteemed. In Scotland it is very frequently sold as turbot. Holibut is best in season in March, April, and May. e. *Turbot* (*Rhombus maximus*). The genus rhombus may be known by their thick-set pointed teeth, eyes being generally placed on the left side, and entire mouth. The turbot itself is the most esteemed of all the flat fishes, and may be known by its numerous round and hardish tubercles, particularly on its coloured side. Its under side is cream-coloured, and on this side it has no scales. It has no red spots, which at once distinguishes it from the plaice. It is often two feet long, and weighs from 12 to 20 lb. It appears to be in season all the year round. Its flavour, which is so much esteemed, probably depends upon the crustaceous animals upon which it feeds. Turbot is the dearest of all fish. Among the Scotch fishermen it is called *bannock fluke*. f. *Brill* (*Rhombus vulgaris*) may be distinguished from the turbot (which as food it almost equals) by its not having the tubercles on its coloured side, and by its colouring, which is fuscous, being spotted with brown-yellow and white. It has scales, too, on both sides. Brill is considerably smaller than turbot, from 1 to 3 lb. being a common weight. It is exposed for sale nearly at all seasons indiscriminately. Its Scotch name is *Bannet fleuk*. g. (*Solea vulgaris*). The genus Solea is distinguished from the foregoing by its twisted mouth, and by the jaws of the eye side having no teeth. The sole inhabits the sandy shores of our island, and its meat is very much esteemed, being firm, white, and delicate. It spawns towards the end of February, and is out of season for a few weeks afterwards. A sole weighs from ¾ lb. upwards. 21. *Eel* (*Anguilla vulgaris*) is one of the fishes that contains oil amongst its muscular texture. In shape it resembles a snake. Its scales are not visible to the naked eye. It is considered to afford good food, but to be difficult of digestion. It is always in season. A pound is a common weight of an eel, although eels very often attain a much larger size. The *conger-eel* (a permanent inhabitant of salt water) may be known by the margins of its fins being black. It grows to an enormous size, sometimes attaining a weight of 100 lb. In the Peninsula it is dried and powdered for the purpose of putting into ragouts, but it is seldom eaten in Scotland. The little *sand-eel*, common on our sandy shores, is properly a launce. 22. *Wolf or Cat-fish* (*Anarrhichas lupus*) is common, and may be recognised by its very ugly appearance, and by its dorsal fin extending the whole length of the back. It furnishes, nevertheless, very good food. In Scotland it is improperly sold as John Dory—a fish altogether different. Its common weight is 3 or 4 lb. 23. *Perch* (*Perca fluviatilis*). The common perch may be known by the spines of its first dorsal fin. It spawns in the beginning of May, and is out of season for a few weeks afterwards. It is considered one of the best of our fresh-water fishes. Sometimes it attains a weight of several pounds, but one pound is perhaps more than an average. 24. *Gurnard* (*Trigla cuculus*). This (like other members of the genus) is common on the English and Irish coasts, weighs about 3 lb., is in season from October to the end of winter, and is considered to afford good food. 25. *Red Mullet* (*Mullus surmuletus*) is taken on the south-western coasts of England, but rarely on our northern shores. It is about a foot long, is in best season in May and June (although sold at all seasons), and is regarded as very excellent food. The *gray mullet* (*Mugil capelo*) is a fish of a different genus, and is abundant on the south and west coast of England. It is 1½ feet long, and its flesh is esteemed. The roe is sometimes made into caviare. It is one of the few fishes that are sometimes artificially fattened. 26. *Mackerel* (*Scomber vulgaris*) one of the most beautiful and delicious of our fishes, is in season from May to the end of summer. It is more common in the southern than in the northern part of our

coast. For some reason not well understood, it is apt to become rapidly putrescent after it is taken from the sea. An ordinary length is from 12 to 16 (sometimes even 20) inches, and the weight from 1 to 1½ lb. The *tunny mackerel* or *common tunny* (*Scomber Thynnus*) is sometimes taken on the western coast of Scotland. It is from 3 to 6 feet long, and like sturgeon its flesh resembles that of quadrupeds. It is much esteemed in France. 27. *John Dory* or *Doree* (*Zeus Faber*) is not a common fish, but is occasionally caught on the Cornish and Devonshire coasts. It is a very ugly animal—its head being disproportionately large for its body. It is very much esteemed. It is in season at the end of spring, and commonly weighs 4 or 5 lb. Unless kept for a day or two after being caught, it is tough.

e. *Invertebrated Animals.*—a. *Crustaceous animals having shelly coverings and feet.*—1. *Lobster* (*Astacus marinus* or *grammarus*). This animal, improperly called a shell-fish, inhabits all the northern seas. The full-grown ones are in season from October to May, but small ones are eaten all the year round. Lobsters are of a blue-black colour, but when boiled their shell assumes a bright red. The male is known by its narrower tail, and is most esteemed, particularly during winter, but the female is found superior for some culinary purposes. The muscular parts of the lobster and of the three succeeding animals contain (we have no exact analysis) fibrine, gelatine, and a peculiar principle to which they probably owe their flavour, and also perhaps their indigestibility. The common *cray fish* (*Astacus palinurus*) is similar but inferior to the lobster. 2. *Crab* (*Cancer pagurus*). The crab is very abundant on all our rocky shores. It is in season all the year except May, June, and July, although individuals may be obtained fit for the table at any season. The male is usually preferred. 3. *Shrimp* (*Crangon vulgaris*). This little animal is common on our sandy shores. It is nearly transparent; but when boiled it becomes of a brownish-red colour. 4. The prawn (*Palæmon serratus*) is analogous to the shrimp, but considerably larger. b. *Molluscous animals without feet.* 1. *Oyster* (*Ostrea edulis*). This much-esteemed animal is in season from September to April. In May it spawns, and requires all the summer to recruit its condition. Oysters are abundant on our shores, where they stick to rocks or other solid bodies, but they are often collected and fattened in beds. They contain about 12 per cent. of albuminous matters, and are therefore moderately nutritious. 2. *Cockle* (*Cardium edule*). This little bivalve burrows in the sand about low-water mark. It is in season in spring, and is palatable. The pecten, the razor-fish, the periwinkle and whelk, are analogous molluscous animals which are sometimes used as food, chiefly by the common people. 3. *Mussel* (*Mytylus edulis*). The sea-mussel lives in flocks on hard ground above low-water mark. It has a peculiar beard by which it sticks to the sand or rock. It is in season in autumn and in spring. It is occasionally poisonous.

f. *Insects.*—Perhaps with the exception of the locust and some larvæ no insect is used by man as food. *Honey*, however, the produce of the bee, is largely used by man. It is probably somewhat modified from its original state in the flower by secretions from the bee. Honey consists of two kinds of sugar, one that will crystallize and therefore be separated in the solid form, and one that will not. It also contains colouring and odorous matter (and some other matters) derived from the flowers upon which the bees feed, and its flavour consequently varies with the plants from which it is gathered. Fermented honey is *mead*—a drink now little used. Honey may be used as sugar, and supplies the system with carbon.

g. *Aqueous Aliment.*—*Water*. As nearly four-fifths of the body of man consists of water, this fluid is a necessary ingredient in his food. All the so-called solid matter that he eats, as has been before stated, contains it most abundantly. It is almost certain that a portion of the water taken into the stomach is decomposed in the system, and yields oxygen and hydrogen. Spring water usually contains a small quantity of saline ingredients derived from the rocks through which it has flowed. When it contains much lime or magnesia it is said to be *hard*. It often too contains a little organic matter.

h. *Condiments.* Only one condiment, common salt (the action of which is inexplicable, none of the theories proposed regarding it being satisfactory), is absolutely necessary, but in civilized countries several others are used for the purpose of promoting the appetite and stimulating the digestion. And notwithstanding the stereotyped outcry, there can be no doubt but that if used in moderation they are conducive to health. 1. *Common salt* is obtained from sea-water and also from salt mines, which are portions of beds of extinct seas. It is indispensable to all food, but it is not known whether it acts as food itself (to afford sodium and chlorine) or for some other purpose. Perhaps it is necessary to form the hydrochloric acid of the stomach. However this may be, every adult man consumes a considerable quantity of it. Two kinds are known in commerce, bay salt or large crystallized salt, and white, basket, or small crystallized salt. Salt is also used for preserving articles of food, and for this purpose the large or bay salt is preferred. Many specimens of salt contain magnesia, but it is essentially composed of chlorine and sodium. The notion that salt or salted meats produce scurvy is erroneous. When this disease breaks out at sea it is not the presence of salted food but the absence of fresh vegetables that excites it. 2. *Vinegar.* What is sold in the shops as vinegar is diluted acetic acid. Four strengths are sold, called Nos. 18, 20, 22, and 24; No. 22 is the best for domestic purposes. Vinegar is often adulterated with sulphuric acid. A small quantity of it is probably assimilated and supplies the system with carbon. It is frequently flavoured with capsicum, tarragon, &c.; and pickles, although the vegetables in them go for something, are essentially spiced vinegar. The use of vinegar as an antiseptic will be afterwards considered. When fresh vegetables cannot be regularly obtained, as in voyages, a liberal allowance of vinegar is found very conducive to health (see Section V.) Lemon-juice, which is a diluted solution of citric acid, is also used advantageously for the last-mentioned purpose. 3. *Spices.* Nearly all the spices are natives of tropical countries, contain aromatic and stimulating essential oils, and yield little or no nutriment, but are unquestionably useful in artificial states of society as promoting appetite and digestion. The most important of them are the peppers, turmeric, cinnamon, cloves, nutmeg, mace, ginger, and pimento. 4. *Seasoning* and *Sweet Herbs.* These resemble the preceding, but are natives of our own climate. They all contain an essential oil, and unquestionably are, if taken in small quantities, useful. The most common of them are mustard, horse-radish, parsley, tarragon, thyme, sage, mint, savoy, and tansy. Capers, which belong to this class, are imported in a salted state from the Levant. 5. *Sauces* and *Compound Condiments.* These are also useful flavouring ingredients. Catsup is the seasoned juice of mushrooms, and sometimes of green walnuts. Soy ought to be the juice of the *Dolichos Soja*, a Japanese plant, but is usually a mixture of fermented pease-juice, catsup, and spices. Anchovy sauce is a solution of anchovies and spices. Curry-powder is a mixture of turmeric, pepper, coriander, ginger, and other flavouring ingredients. The various sauces of the shops have for their base catsup, and their difference consists in their seasoning ingredients.

III.—*The Modes of Preparing Food for Human Use, and the rationale of their respective actions.*

Most animal and vegetable articles of food are exposed to heat before being used. The effect of this is in albuminous compounds to coagulate the albumen, to promote the formation of osmazome and kreatine, and to expel a portion of the water (and fat, if any be present). Heat applied to starchy compounds (if, as is always the case, water be present) causes them to swell, and the starch grains split, and form more or less of a homogeneous mass, and in this way they become more palatable, and also in a state that the digestive juices can act better upon them. And vegetables too, in some manner which it is not easy to explain, lose by the application of heat a great part of their acidity, and sometimes sugar is formed in the process. The operations of cooking may be divided generally into roasting, baking, broiling, frying, boiling, and stewing, and to these may be added the making of bread, the processes connected with vinous fermentation, distillation, and vinegar-making. 1. *Roasting.* Professor Wallace many years ago made some experiments relative to the loss of weight sustained during this process, and he found that taking 10 lb. joints, the average loss of 100 lb. of beef in roasting was 32 lb., of necks of mutton 35 lb., of shoulder of mutton 31⅓ lb., and of legs of mutton 21⅓ lb. But in Professor Wallace's experiment fatter meat was probably used than what is customary now; and he did not ascertain the amount of bone. The inquiries of Donovan are more instructive, and the conclusion that he came to is that the loss in roasting in the best piece of beef (as the sirloin), is 19½ per cent., in a fore-quarter of lamb 22⅓, in a goose 19½, in a turkey a little more, in a duck 27⅕, and in a chicken 14⅜ per cent. The proportion of the bones in a roasted joint of meat, as ascertained by the same experimenter, is also important. He took a piece of the longer ribs of beef that weighed 11¼ lb. This when roasted lost 2 lb. 6 oz., of which 28 oz. were water and 10 fat, &c. The meat was then dissected from the bones, and these were found to weigh 16 oz. Consequently, of the original joint which weighed more than 11 lb. there was less than 8 lb. of meat; so that if it was bought at 8½d. a lb., the roasted beef that could be actually consumed would cost more than 1s. a lb. Part of a sirloin of beef that weighed 12 lb. lost by roasting 44 oz., of which 27 were water and 17 fat, &c. The bones weighed 2 lb., and the beef that was actually suitable for eating weighed 7¼ lb. Hence if the cost of the joint were at the rate of 8½d. per lb., the value of the roasted meat would be 1s. 2d. per lb. A leg of mutton that weighed when bought 9¼ lb., lost when roasting 1 lb. of fat, &c., and 14 oz. of water. The bone weighed 16 oz. Only 6 lb. 6 oz. were left, and if the butcher had

charged 8d. per lb., the cooked meat would cost more than 11d. per lb. Lamb, it was found, lost a little more by roasting than mutton. A goose (not stuffed) prepared for roasting weighed 5½ lb. When roasted it was found to have lost 18 oz., and the bones weighed 12 oz. The edible part that remained, therefore, if the goose sold at 1s a lb. would be worth 1s. 8½d. A turkey properly trussed weighed, including its liver and gizzard, 6 lb. 11 oz. It lost 20 oz. in roasting, and its skeleton weighed nearly 14 oz., the weight of its edible part being 4 lb. 10 oz. Had the original price of the turkey been 5s. the value of the roasted meat would be 1s. 1d. According to the same authority, a duck when prepared for roasting weighed 1 lb. 10½ oz. In roasting it lost 6½ oz., and the bones weighed 4 oz. The edible portion was therefore only about 1 lb.; and if the duck cost 2s. or 1s. 8d., the food it yielded would be this sum per lb. A fowl weighing 1½ lb. lost 3 oz. when roasted, and its skeleton weighed 3½ oz. The edible portion therefore was 16½ oz. At the price fowls commonly sell at, the cost of the roasted meat would be 1s. 6d. per lb. 2. *Baking*. The difference between roasting and baking consists in this, that in the latter process there is no free current of air allowed, the result of which is, that less water is evaporated, and that also less oil is expressed out. Hence baked meat is partly roasted by the hot air, and partly boiled in its own water and fat. Wallace found that 100 lb. of meat lost in baking 30 lb., being 2 per cent. more than the same quantity, in his experiments, lost when roasted. 3. *Broiling*. This is a very rapid mode of roasting, by means of applying more intense heat, the substance to be cooked being placed immediately over instead of before the fire. The albumen at the outside of meat so cooked is immediately coagulated, and a little crust formed, which (unless the meat be pricked with a fork), prevents the escape of much water, fat, or gelatine. 4. *Boiling*. The following experiments of Donovan's show the loss sustained by boiling various articles of food, and consequently the value of the soup. A piece of flank of beef weighing 10 lb., had 8 oz. of bone. It was boiled and found to lose 23 oz. Supposing, therefore, it cost 6d. per lb., its price when cooked would be 7½d. A leg of mutton weighed 9¼ lb. When boiled its bone including its shank weighed 1 lb., and the loss of the meat was 1 lb. 2 oz. If it cost 8d. a lb., it would be worth when boiled 10¼d. A ham without its shank that weighed 8 lb. was boiled. The bone weighed 8 oz, and the loss by boiling was 1 lb., and by skinning and browning (a partial roasting) ½ lb. The meat that was left therefore weighed 6 lb. Had the ham cost 10d. per lb., when cooked it would be worth 1s. 11½d. per lb. A piece of bacon that previously weighed 4 lb., lost by boiling 4 oz. The bone weighed 2¾ oz., and the skin and loss by boiling amounted to ½ lb. The edible portion weighed 3 lb. 1 oz. If it originally cost 8d. a lb., the meat when cooked would be worth 10½d. per lb. A turkey that weighed 4½ lb. and which cost 3s. 6d., lost 12 oz. in boiling, and its bones weighed 10 oz. The edible portion therefore amounted to 3 lb. 2 oz., and had cost at the rate of 13d. per lb. A chicken that weighed 1½ lb., lost 3½ oz. by boiling, and its bones weighed 4 oz. This left 12½ of meat, which, if the chicken cost 1s. 6d., was worth nearly 2s. per lb. A turbot that weighed 9 lb. and cost 7s., lost in boiling 8 oz. and its bones weighed 21 oz. Hence its edible part after cooking amounted to 11½d. per lb. The following table prepared from the same source shows the average loss from roasting and boiling:—

		per cent.			per cent.
Loss in roasting	beef,	19⅕	Loss in boiling	salt beef,	15
...	mutton,	24⅘	...	mutton,	10
...	turkey,	20½	...	turkey,	16
...	chicken,	14⅗	...	chicken,	13½

a. *Soup-making*. Soup is a decoction in water of a good deal of gelatine, some fibrine, albumen, phosphate of lime, other salts, and osmazome. The fibrine, however, rises to the surface and is skimmed off. Of course, vegetables, as will be seen by a reference to their chemical composition, yield exactly the same kind of soup as butcher meat or fish. In practice, however, a mixture of animal and vegetable matter well boiled is found to afford the most economical soup. Animal soup probably contains little albumen, but when vegetables are boiled down, their albuminous proximate principles are quite mixed up with the fluid. This is probably the reason that the vegetable or nearly vegetable soups so much employed by the labouring classes in Scotland and France are found to produce in their consumers such a high degree of material vigour. Soup also perhaps contains some kreatine and certainly generally lactic acid; and Liebig affirms that the addition of the latter (in the form of sour krout) improves the flavour of the soup; but the experience of English gastronomists at least scarcely confirms this opinion. The same distinguished chemist also affirms that chloride of potassium improves the piquancy of soup. 4. *Stewing*. By this method of preparing meat, less of the principles of the meat are absorbed by the surrounding menstruum, and the greater portion of the gelatine in particular remains among the coagulated albumen. Hence stewing is an economical form of cooking. 5. *Frying*. In this culinary process it is probable that a portion of the glycerine of the fat is decomposed, and that a new substance or principle is formed, which principle seems somewhat difficult of digestion. 6. *Bread-making*. Common fermented wheaten bread is made by mixing flour, water, salt, and some albuminous matter, either yeast or leaven (*i. e.* a piece of old bread), and placing the compound in a warmish situation. Two catalytic actions very soon begin; a portion, and the greater portion, of the sugar, is converted into alcohol and carbonic acid; the greater part of the former of these compounds is evaporated (by the after heat of the baking), but the carbonic acid gas is retained among the tenacious gluten, and produces the vesicular structure that characterizes ordinary fermented bread. Then some of the starch is likewise converted into sugar. If the alcoholic fermentation be allowed to go on too long, it runs into the acetous, and the bread consequently becomes sour. It is said that the salt employed in the mixture, besides communicating flavour, communicates stiffness to the dough, probably by abstracting some of its water. After these changes have taken place the bread is baked, the result being that a considerable quantity of water and the alcohol are driven off and the albumen is coagulated. 100 lb. of flour produce 139 lb. of bread; but the apparent gain is derived from the water that is used—the flour being diminished in quantity by the conversion of part of it into alcohol and carbonic acid. The baker often adds potato-flour and also alum to his dough. The latter adulteration makes the loaf whiter, but is highly injurious to the consumer. Brown or household bread differs from white bread, in the flour of which it is made containing more or less of bran. Rolls are made to ferment more rapidly than loaf bread by adding more ferment, and hence are more porous. None but wheaten flour is used in this country for making leavened bread, but formerly rye or black bread, still so common abroad, was extensively employed. For many years occasional attempts have been made to make bread spongy by adding to the dough, in place of yeast, hydrochloric acid and carbonate of soda. Carbonic acid is given off, which mixes among the gluten and makes the bread light, and chloride of sodium or common salt is left behind. In this manner the waste caused by the conversion of the sugar into alcohol is avoided. Properly prepared gingerbread is rendered porous in a similar manner. Carbonate of potassa and treacle are added to the dough. Treacle contains a free acid which combines with the potassa salt and liberates the carbonic acid. Some kinds of light bread are rendered porous by adding carbonate of ammonia to the dough, the ammonia of which is expelled by the heat of the oven; and some cakes are made light by the addition of carbonate of magnesia. Wheat flour is also used unfermented in various ways—as in pastry, biscuits, macaroni, &c. &c. (See BAKING). 7. *Wine and Vinegar Making*. Grape wine is now rarely made in this country, as the grape grown out of doors rarely contains sugar to afford an alcoholic mixture that is strong enough. Raisin wine, however, it is believed, is pretty extensively made, and the greater part of it sold as sherry. Domestic wines are made by fermenting the juices of currents, gooseberries, and other fruits, with the addition of sugar and tartaric acid, and frequently a little spirit. Vinegar is oxidated alcohol, and is usually prepared by fermenting a saccharine solution, and then exposing the diluted alcohol thereby obtained to the air.

IV.—*The Modes of Preserving Articles of Food from Decomposition.*

The elements that compose all living structures, vegetable or animal, are grouped together in obedience to certain laws of vital affinity. But this obedience is transitory, and whenever life departs from an animal or plant, they tend to, and ultimately always do, return to the dead world, and become subject to the laws of chemistry. The series of changes that they undergo in thus passing from one arrangement of their elements to another is termed putrefaction, and consists mainly in the following processes:—The carbon absorbs oxygen from the air, and carbonic acid is formed and given off; some of the hydrogen and oxygen unite together and form water, and another portion of the hydrogen unites with the nitrogen (if any be present) and forms ammonia, while another portion of it unites respectively with carbon, phosphorus, and sulphur, the results being carburetted, phosphuretted, and sulphuretted hydrogen gases, the last of which communicates a great part of the disagreeable odour of putrefying food. Very probably, too, kreatine, &c., are formed and decomposed during the putrefying process. An albuminous substance putrefies the most rapidly, owing to its albuminous compounds acting catalytically as a ferment. A purely saccharine or oleaginous substance putrefies much more slowly, and is only resolved into water and carburetted hydrogen, and hence has little bad smell. It often becomes previously converted into vinegar. In order, however, that putrefaction take place, two conditions are necessary—in the first place, water must be present, and it is indispensable, at

least for rapid putrefaction, 1st, That the alimentary matter be exposed to oxygen, or, what comes to the same thing, to air. This enables us to understand why one article of food putrefies so much sooner than another. If a piece of meat, for example, be exposed to the atmosphere, say in the month of September, along with a bone and a potato, the meat being fully exposed to the air, and containing a large proportion of albuminous matter and water, soon putrefies; while the other two—the one containing little water, and the other protected from the air by its skin, retain their structure for a number of months. 2d. Heat, in virtue of the power it possesses of removing its atoms from one another, strongly predisposes to putrefaction; so also does the presence of any other putrefying substance, which seems to act catalytically. This action may be counteracted by excluding the air or the water, and also by the use of certain antiseptic substances, as salt, sugar, vinegar, &c., the action of most of which, however, is to be explained by the property that they possess of acting upon air or of abstracting water. If meat appear likely to become tainted, it may be preserved for a few days by any of the following means:—It may be kept enveloped in a wet cloth, which in consequence of the evaporation produces cold; it may be slightly smeared over with pyroligneous acid; it may be surrounded by a little powdered charcoal, which absorbs the sulphuretted hydrogen and other decomposing gases; or it may be kept in an atmosphere of creasote. This last seems to be a most effectual plan, and Dr Stenhouse of Glasgow reports most favourably of its success, not only with himself, but also with a butcher who tried it. 1. Articles of food may be preserved from putrefaction for a very considerable time by expelling the water they contain by the action of heat. Indeed something of this kind is occasionally witnessed in nature; and in hot sandy deserts where rain seldom or never falls, the bodies of camels and of travellers are found undecomposed, and have probably been so for ages. Advantage is seldom taken in this country to preserve vegetables in this manner, although the kiln-drying of wheat and other grains is partly a process of this nature, and the usual manner of preserving sweet or pot-herbs is essentially so. Abroad, and sometimes perhaps here, apples and pears are sliced and put into a heated oven, so as to expel the water, and the fruit thus dried may be kept for a considerable time. The flesh of mammals is rarely so preserved in this country, but the Indians thus prepare *pemmican*, an imitation of which made of beef, but which is generally also smoked, has been employed in our Arctic expeditions. It was in this way the buccaneers preserved their beef. Portable soup is essentially a dried meat. It is made by preparing a strong beef soup from a bony piece, as the leg of an ox, skimming off the fat, and then evaporating the water. According to Liebig, the test for distinguishing the true extract of flesh from the spurious imitation, which consists almost entirely of gelatine, is that 80 per cent. of the true extract is soluble in alcohol, and only 4 or 5 of the gelatine cakes. 2. Many articles may be preserved from putrefaction by means of solidifying the water they contain by applying cold. Water becomes solid at 32°, and when the water of a structure has been thus converted into ice all putrefaction is impossible. Thus the fossil elephant that was found imbedded in Siberia was quite fresh although it had probably been so imbedded for thousands of years. This mode of preserving food, however, is not applicable to vegetables, for the starch of a frozen vegetable is almost certain to be converted by frost into sugar. But in cold countries, as in the north of Russia, Canada, &c., it is very extensively used as a means of preserving flesh, whole animals being often frozen, and thus kept throughout winter. If, however, frozen meat be not gradually and slowly thawed by being at first immersed in cold water, putrefaction comes on so rapidly that the meat is unpalatable. In this country butcher meat is seldom or never preserved in this manner; but fish, especially salmon, is so on a very large scale. Every salmon-fishery of any consequence in Scotland has an ice-house, and the salmon intended for the English markets are packed in the ice and thereby frozen or nearly frozen. In this manner they reach their destination in a fresh state. The fishmongers too preserve their other fish in a similar manner. 3. Articles of food may also be preserved from putrefaction by excluding them from air. This has long been done in a great variety of ways. The oldest and most imperfect of these is potting, which is usually performed by beating up the meat into a paste, then putting it into jars and covering it up with clarified butter. Another variety of meat similarly preserved is the common sausage. The exclusion of air, however, is only partial, and consequently sausages do not keep very long. This defect is obviated in the Bologna sausage by smoking the meat of which it is made. Long ago, Mr Boyle tried the experiment of keeping food in an exhausted receiver, and he found that no putrefaction took place; but the plan of preserving food by thoroughly excluding the air was scarcely carried into practice until 1810, when M. Appert (who seems to have been quite ignorant of Boyle's experiments) published his plan of effecting this, and received a reward for it from the French government. Since then his method, with some modifications of detail, has been extensively pursued. It consists in first coagulating the albumen of the animal and vegetable structure to be preserved by parboiling it, and thus attaining two ends, the coagulated albumen being far less disposed to putrefy than uncoagulated, and a great portion of air being drawn off; and secondly, in putting the parboiled food in jars or bottles (the latter in the case of liquids), and plunging these into boiling water, which expels a great portion of the remaining air contained in the food. Some air indeed always remains, but the oxygen of most of it combines with carbon and forms carbonic acid; why, it is not very easy to say. The jars are then hermetically sealed, and their imperviousness to air tested. At present, instead of bottles tin canisters are employed, and these have the additional advantage of collapsing a little from atmospherical pressure. As, however, some air is left, the food eventually putrefies. Meat prepared in this manner sells from 1s. 3d. to 2s. a lb., soup from 2s. upwards per quart, and milk at about 1s. a pint. The various plans followed for the preservation of eggs all depend upon the exclusion of air. A simple plan is to stop up the pores of the shell by smearing the eggs with some unctuous substance, as suet. Another mode is to pack the eggs in bran, salt, &c. A third is to boil them for a few seconds, and thus form a small layer of coagulated albumen underneath the shell. It should be observed that eggs are very apt to contract an unpleasant flavour from the readiness with which they absorb odorous effluvia. Thus, when packed in old straw, their flavour is frequently much affected. 4. Articles of food may be preserved from putrefaction by means of salt. This plan has been practised from time immemorial, and in this country, before the turnip culture allowed the farmer to furnish continuous supplies of butcher meat, was even much more extensively used than now. One part of the action of the salt is to abstract a great part of the water, another is to abstract the juices from the outside (thereby forming brine), and thus to envelope the meat in a hardened case which more or less excludes the air; but there is probably some other property of the salt of an antiseptic nature, the exact nature of which is not known. As all articles of food preserved by salt retain a portion of the salt in their texture, they are always a little firmer in their structure than the same foods unsalted. In the ordinary manner of salting animal food, about one-third of the juices, including some of the soluble albumen, passes off into the brine. If this statement be correct salted meat is of course much less nutritious than fresh. Liebig proposes to employ a salt that contains chlorides of calcium and magnesium. The lime and magnesia, according to him, unite with the phosphates of the juice and cover the meat with a crust or white froth of phosphates of lime and magnesia which effectually keep in the juices. It is generally believed among practical salters that the salt which occurs in large crystals or bay salt is preferable to the finer kind, and as bay salt is not so pure as the fine, this would appear to confirm Liebig's hypothesis. In salting a piece of meat or of fish, the salt is generally rubbed in, and the brine allowed to run off, and in this case it is then dried and frequently smoked. When the food is kept immersed in the brine it is said to be *pickled*. Vegetables are sometimes salted dry, but generally pickled. It is also very common to add nitrate of potassa or saltpetre in the salting of flesh. This substance acts as an antiseptic by abstracting water, but it also forms a compound of a red colour with meat. Sugar, another antiseptic, is also now commonly added to the salt and salt brine, and frequently also spices for the purpose of communicating a flavour. 5. Articles of food may be preserved from putrefaction by means of sugar alone. Sugar is a powerful antiseptic, part of its action being owing to its abstraction of water; but it also possesses a peculiar but inexplicable power of preventing a substance with which it is placed in contact from obtaining oxygen. Sugar, however, although much employed mixed with salt, is seldom used alone to preserve animal food; some fish, as salmon and mackerel, are occasionally so preserved, but the great application of sugar in this respect is to vegetables. Sometimes fruits are preserved in a strong syrup (strong to prevent it running into the alcoholic fermentation); sometimes the water of the syrup is evaporated, the result being a dry confect or a candy; sometimes a portion of the water of a fruit is evaporated, and then sugar added, the result being a jam when it is pretty moist, and a marmalade when it is drier; and sometimes only the juice of a fruit is preserved, and in this case the product is called a jelly. Honey is equally efficacious as sugar in these respects, but it is seldom so used. Fruits preserved by means of honey used formerly to be called confections. 6. Articles of food may also be preserved by means of pyroligneous and acetic acids. Under this head may not only be included the direct application of the acids, but also the employment of creasote and of wood smoke. The action of all these is the same, and consists in coagulating the albumen at the surface, and thereby preventing the access of air. The application of creasote to meat to protect it for a few days has

been noticed above; but if meat be dipped in it and then dried, it may be kept for a very long time without decomposing; but this process is rarely adopted in this country. The smoke of burning wood, however (which contains creasote), is very much employed to cure both meat and fish. These substances are usually first salted and then exposed to the smoke of bark or oak-wood, to which juniper, rosemary, &c., are sometimes added. Bacon hams, tongues, pieces of beef, herrings, salmon (then called kippered salmon), are extensively treated in this manner, and haddocks (then named Finnan or Findon) are preserved by wood smoke alone, without any application of salt. It is now known, that if a piece of meat or a fish be slightly smeared over with pyroligneous acid, or dipped in it for a few seconds, it is protected from putrefaction, and has the same flavour as smoked food. Common vinegar obtained from alcohol is not used for preserving any article of food derived from a mammal, but it is used to coagulate the albumen of some fish, as salmon and herrings, and of some mollusca, as oysters. The antiseptic properties of vinegar, however, are principally taken advantage of for the purpose of preserving vegetables. As vegetables contain much water, it is necessary either to use a strong vinegar, or to abstract a portion of the water of the vegetable intended to be acted upon. In practice the latter is done by adding salt to the vegetable, and pouring off the brine that is in that manner obtained. Sour krout so much used abroad, is also in part a pickle, but the cabbage of it would seem to undergo also a fermentation of its own, in which probably lactic acid is formed. 7. Articles of food may also be preserved in alcohol, which acts by coagulating the albumen; but owing to its expense it is never applied to animal food, and only on a small scale for preserving some of the finer fruits.

V.—*The Principles of Dietetics.*

The human body consists of the following elementary bodies variously combined together,—oxygen, hydrogen, nitrogen, carbon, sulphur, phosphorus, potassium, sodium, calcium, magnesium, chlorine, and iron. These are probably arranged so as to form water, albuminous proximate principles, oleaginous ones, and to a very small extent saccharine ones, all these being grouped together so as to form flesh, glands, bones, &c. All these elements must be taken into the human body in the form of food, and they must exist in the combinations that they have acquired in vegetables or in animal flesh that has been nourished on vegetables, either directly or indirectly, through the medium of a herbivorous feeding animal. But even when an adult man has taken into his stomach the amount of the above elements that he requires, either in the form of vegetable or animal nutriment, and has by means of his organs of digestion and assimilation converted them into his own oleaginous, albuminous, and other principles, these elements can only remain a part of his frame for a very limited time. After a short interval they become putrid and poisonous, and are cast off as excretions. The weight of these excretions correspond each day, in a healthy individual, exactly with the weight and the food that, under the guidance of appetite, is taken in the same period, with this exception, that a large amount of carbon in the form of wine, alcohol, fat, &c., requires to be likewise received into the system to serve as fuel, combine with oxygen, and so keep up the animal heat. In a growing person, as a child, there is required an amount of food which, besides replenishing the daily waste, will also afford material for the new structure that is daily being added to the bulk. It may be also stated, that the rapidity with which the structures are wasted and the carbon consumed, depends very much on the amount of exercise that is taken; and accordingly the daily quantity of food varies in different individuals, and in the same individuals in different circumstances.

From the structure of the teeth, and from the relative conformation of the stomach and intestines, comparative physiologists judge that man is omnivorous, and facts in his habits certainly confirm the conclusion. Many men, as the natives of Bengal and other countries, live entirely upon vegetables; and others, as the Esquimaux, altogether upon animal food, while most examples of the human species use a mixed diet of animal and vegetable matter; and the majority of people find it most convenient to obtain a portion of their supply of carbon from fermented drinks, or from drinks distilled from such. The number of people who abstain from fermented drinks, however, proves that the requisite amount of carbon may be obtained from saccharine or oleaginous compounds, the deficiency being in general, probably, made up from the latter. There appears, nevertheless, to be little doubt but that, in order to attain the full perfection of the mental and bodily faculties, an admixture of animal and vegetable articles of food is essential; and also that a portion of the carbonaceous supply should be derived from alcoholic drinks. Those who live almost entirely upon animal food become stunted in growth, and liable to ravages of scurvy, and their mental and moral faculties are blunted and sensual; those who consume only vegetables are generally inactive and listless, and incapable of either active bodily or mental labour; and independently of other objections, there is reason to fear that the offspring of those who abstain entirely from fermented drinks become in a generation or two enervated in mind and body. It is probably in this last-mentioned manner that the decadence of the different Mohammedan nations and races is to be accounted for, at least in part.

The subject of digestion will be fully treated of in another place; but it is necessary here to notice some facts connected with it that have a more immediate bearing upon dietetics. Plants, and the classes of animals living fixed to a spot, appear to be almost constantly taking in food, and have no receptacle in which to close it. The higher animals, as man, have however such, or a stomach which receives and contains the various articles of food for some time before they are assimilated. The relative capacity of this stomach varies much in the different classes of animals. In the carnivorous, who live upon food that contains little water, and is therefore concentrated, it is small; in the herbivorous, with the members of which the contrary is the case, it is very large, while in man it is midway between the two. The proximate principles of animals and plants, when taken into this stomach, are acted upon by the gastric juice there secreted, (and which juice consists of water, hydrochloric acid, and pepsine,) and are converted into a pulpy mass, chyme, from which the albuminous, oleaginous, and saccharine principles (the mixture of which is called chyle) are absorbed and poured into the blood to be expended in nourishing and warming the body. The length of time that it takes for food to be converted into chyme varies according to the kind of food taken, in different individuals, and in the same individuals at different times; for digestion, although an organic process, is nevertheless influenced by states of the nervous system. Dr Beaumont made some experiments upon a man who had an opening into his stomach from his side—the consequence of a wound. He ascertained the length of time occupied by various articles of food to become digested. The following are extracts from his table, but they only give approximative results, and it is certain that many of them did not hold good in the majority of people:—

	hr.	min.		hr.	min.
Boiled rice,......................	1	0	Boiled eggs,.....................	3	0
Boiled tripe,....................	1	0	Beefsteak,.........................	3	0
Boiled salmon trout,.........	1	30	Boiled mutton,..................	3	0
Fried do.	1	30	Roasted mutton,..............	3	15
Broiled venison,...............	1	45	Fried flounder,.................	3	30
Boiled tapioca,.................	2	0	Cheese,............................	3	30
Boiled barley,..................	2	0	Mutton soup,....................	3	30
Boiled milk,.....................	2	0	Bread,...............................	3	30
Raw eggs,........................	2	0	Broiled veal,.....................	4	0
Raw cabbage and vinegar,	2	0	Boiled fowl,......................	4	0
Boiled turkey,..................	2	25	Roasted do.,.....................	4	0
Roast do.	2	30	Boiled salt beef,...............	4	15
Roast sucking pig,...........	2	30	Boiled pork,.....................	4	30
Roast potatoes,................	2	30	Fried veal,........................	4	30
Boiled beef,.....................	2	45	Boiled cabbage,................	4	30
Raw apples,.....................	2	50	Roast pork,.......................	5	15
Raw oysters,....................	2	55			

From more satisfactory and often repeated dietetic experiments it appears certain that food is more rapidly converted into chyme when cooked than when raw, although some people appear to be able to digest fruit, salads, and raw oysters with rapidity. Salted meat appears to be longer of digestion than unsalted, and so also do pickled vegetables than fresh ones. Animal food is certainly more rapidly digested when in a state of incipient putrefaction than when subject to the contraction of tonicity. The meat of young animals takes longer to become converted into chyme than that of old of the same kind, owing to the gelatine that it contains requiring a long time to digest. The old opinion that cooked vegetables are more difficult of digestion than cooked animal substance would seem to be quite unfounded.

With regard to the intervals between meals and the times of taking food, strong statements have been made by writers upon dietetics which have perhaps no very exact foundation. Some carnivorous animals, as serpents, only require a meal once in several weeks, but carnivorous mammals seem to need a supply of food once in the 24 hours. Dogs, for example, require feeding once a-day; but it is found with regard to them, and also to hyenas, &c., kept in zoological gardens (but it must be remembered that these animals get very little real active exercise), that two meals a-day decidedly injure their health. On the other hand, graminivorous animals, as sheep, oxen, &c., eat almost incessantly. The conformation of the digestive organs of man, and his omnivorous habits, would indicate a mean between these two. But he has unquestionably a singular power of accommodating himself to circumstances with regard to the interval between his meals. It is plain that one meal a-day was and even yet is not a very uncommon regimen. But now, especially among those classes that labour principally with their minds, the principal meal or dinner is taken late in the day, and a smaller

meal or breakfast is taken immediately after rising. Members of those classes who physically labour also take at least two meals, but such often work for an hour or two before breakfasting, and appear none the worse for their procrastination. But most of the members of the first-mentioned class feel their energies and strength not entirely recruited until some food has been taken, and that if they do not breakfast immediately after dressing, they experience a sensation of lassitude and muscular debility during the whole day. If only two full meals are taken in the day, and the one immediately after rising in the morning, it seems reasonable enough to eat the latter, or dinner, in the evening. It is sometimes assumed that digestion should never stop in the human stomach, and that as breakfast is soon digested dinner should be taken in the middle of the day, but there seems to be no good reason for admitting this as a general rule. Many people, however, do feel exhausted if they do not take in the middle of the day a small lunch, and experience shows that if too much albuminous matter be not then taken into the system the habit is at any rate quite innocuous. The meal called tea, taken soon after dinner, is in fact a part of dinner. To those who dine late, suppers, beyond very slight ones, seem unnecessary, and are certainly often injurious.

There is another important alimentary law which applies to human dietetics. It is, that without a due and pretty regular allowance of fresh vegetable food, not only does the strength become impaired, but the very dangerous disease of scurvy is induced. Before the present system of agriculture was established this pestilence was endemic every spring and latter part of winter, and still later it played fearful ravages among sailors during long voyages. Since, however, there has been a supply of potatoes and other vegetables during winter on land, and since some vegetable juices have been regularly supplied to sailors, the disease has nearly vanished, and has only occurred occasionally where fresh vegetables have been for some time neglected to be consumed.

The following then may be laid down as established facts regarding the philosophy of the food of man:—1. Articles containing albuminous proximate principles must be frequently received into the system to supply the continual waste of the economy, and these may be derived from either the animal or vegetable world. A mixture of the two, although the amount of nutriment and relative digestibility be nearly equal, seems the best. 2. A large amount of food rich in carbon must be also regularly taken into the system for respiratory purposes, and this may be done by means of oleaginous animal or vegetable principles, or saccharine principles, or by means of substances derived from saccharine ones. 3. It is indispensable to take, besides, some fresh vegetables or vegetable acids. 4. Almost all articles of food are more digestible when cooked than when raw. 5. The hours of taking food and the intervals between meals are, with a moderate limit, of little consequence; and an approximation to regularity from day to day seems to be the most important matter to aim at.

FOOD, Adulterations of. It has long been known that very fraudulent, and sometimes very unwholesome, adulterations of food are extensively practised; but until lately it was not easy in all cases to pronounce decidedly on the nature of the fraud that had been committed. Now, however, by means of the microscope and the chemist's test tube, there is little difficulty in so doing, and many important disclosures have by their use been made. The proprietors of the *Lancet* employed Dr Hassall (one of the most accomplished of the microscopical observers of our day) to thoroughly investigate the subject, and his reports have appeared from time to time in that periodical. As he published the names of the different tradespeople from whom he bought spurious or adulterated articles of food, and as none of them have succeeded in disproving (and indeed very few have ventured to contradict) any of the statements, the thorough accuracy of the report may be relied upon, and the facts in this article are based upon it. Although Dr Hassall purchased the articles of food that he examined from London shopkeepers, there can be no doubt that the same adulterations will be found in the provinces. Indeed, the great adulterators are the wholesale houses, who supply indiscriminately London and country shopkeepers.

1. *Adulterations of articles of food not avowedly of a manufactured nature.*—Milk, usually supposed to be much adulterated, is comparatively little so. In towns water is generally added to it, and a portion of the cream is likewise abstracted; but chalk, gum, &c., are very rarely employed (as has often been alleged) to give the appearance of greater strength. Salted butter is frequently melted, and when in that state has water added to it. In this manner fifty per cent. of water may, it is said, be incorporated. Lard is mixed up with water, potato flour, and refuse mutton fat, and the amount of the potato starch has sometimes been known to amount to twenty per cent. Oatmeal, in London, and perhaps elsewhere, is extensively mixed with barley meal; the latter, as it contains so much more water, only selling for about half the price of the former; but wheat flour, unless it contains alum (as it perhaps does), seems quite pure. Arrowroot is adulterated to a large extent. Of 50 samples, bought from London shops, Dr Hassall found 22 to be impure; of these, 10 scarcely contained any arrowroot at all, but were made up of sago, tapioca, and potato starch; while in the others there was a considerable admixture of these cheaper articles. Raw sugar has many impurities, among which the immense number of acari with which it swarms are the most disgusting, but it is also extensively mixed with flour (apparently to make impure dark sugar appear like purer and lighter-coloured), and perhaps with other foreign ingredients. Loaf-sugar seems sufficiently pure. Tea is in a lamentable state, for it is meddled with by both the Chinese and those through whose hands it passes here. With regard to black tea, Dickson maintains that the Chinese mix with their exportations of tea to this country many millions of pounds of leaves of other plants, which they mix with genuine tea plants. In other respects, however (and even, perhaps, in this), the Chinese do not adulterate the common black teas, as Congou, Souchong, and ordinary Pekoe; but other descriptions, as scented Orange Pekoe and Caper, are, almost without an exception, impure; the former by being glazed with black-lead, and the Caper by being extensively mixed with Paddy and Lie tea (*i.e.*, an imitation of tea leaves obtained from other plants), or by not containing any tea leaves at all, but altogether other leaves sprinkled with tea dust, and made up into little masses by means of gum, and which masses are glazed with plumbago, turmeric or Prussian blue, and the whole sprinkled over with mica, &c. But imitation black teas are also entirely made up of the leaves of indigenous plants of this country, as those of sycamore and horse-chestnut, broken down, sprinkled with catechu (to communicate tannin), dried, and coated with gum. But a still more common imposition is to purchase exhausted tea leaves (which are sold at about 3d. a lb.) from hotel-keepers and the like, and attempt to imitate fresh tea by admixture with catechu, gum, sulphate of iron (to strike a dark colour with the catechu), Prussian blue, logwood, black-lead, talc, &c. Some of these adulterations—as the Prussian blue, for example—are calculated to have serious effects upon the health. Green teas are more adulterated than black ones, a really unadulterated specimen being very rarely to be met with. They are mixed in China with leaves of other plants, are subsequently glazed with gum, Prussian blue, turmeric, and various other substances, some of which are very unwholesome. Imitation green teas of British manufacture are also occasionally, perhaps even often, exposed for sale. Coffee, until the government interfered to prohibit the sale of a mixture of coffee and chicory as "coffee," almost invariably contained a large, and sometimes an amazingly large, admixture of chicory. Several contained in addition roasted corn, beans, potatoes, sometimes red ferruginous earths, and other impurities. Ground chicory itself, so much employed to secretly mix with coffee, is itself an article extremely adulterated. Nearly a half of the specimens examined were largely so, the substances employed for the purpose being roasted wheat, ground acorns, mangold-wurzel, carrots, magohany sawdust, and ferruginous earths,—the two latter for the purpose of communicating colour. Cocoa and chocolate are no better, the great majority of samples of them being largely mixed with sugar, and with potato, and other starch; but a worse adulteration is, that they also contain colouring earthy matter (usually, probably, of a ferruginous nature, but which sometimes perhaps have for ingredients red lead and vermilion, two very dangerous ingredients), and tallow and other fats seem to be sometimes mixed with them. The acknowledged substitutes for tea, coffee, and cocoa, as *Revalenta, Semola, Prince of Wales' Food*, &c., &c., are very familiar substances. Du Barry's much vaunted "Revalenta" is a mixture of pounded lentils and barley meal, and the syrup that accompanies it is treacle. Bullock's "Semola" is the gluten of wheat with a little starch; and "the Prince of Wales' Food" is potato flour.

Ground ginger is very commonly, and very largely adulterated. Dr Hassall found three-fifths of his samples to be so, the substances admixed being sago-meal, potato flour, common flour, ground rice, cayenne pepper, and mustard husks,

and these generally constituting the greater part of the bulk of the powder. Mustard—*i.e.*, ground—is almost invariably adulterated, the articles employed for the purpose being flour and turmeric, and these sometimes constitute nearly the whole of the article. Pepper is likewise very frequently mixed with linseed meal, pea meal, powdered mustard, and other substances cheaper than itself. Cayenne pepper is scarcely ever sold pure; and as the adulterations employed are bisulphuret of mercury, red lead, and other mineral colouring-matter, cayenne pepper is often a pretty active poison. In like manner, curry-powder, of which four samples out of five were found to be adulterated, frequently contains red lead, and is therefore very deleterious. Of the other spices, cinnamon and mixed spice are often impure; but pimento, mace, cloves, and turmeric, are almost always pure. Vinegar was found by Dr Hassall to vary a good deal in strength, and also in the quantity of sulphuric acid that most of it contains; many samples containing more of this than was formerly allowed when the vinegar-makers were under the control of the excise; but some specimens, and these very good vinegars, were found to contain none of it, and this is a satisfactory proof that the addition of sulphuric acid is by no means necessary to vinegar.

2. *Adulteration of articles of food avowedly of a manufactured nature.*—Although some of the above adulterations communicate poisonous properties, yet most of them are frauds merely; some of which, however, must press very severely upon the artisan, to whom a nominally cheap article is almost irresistible. But the adulterations now to be noticed are all of a deleterious nature, and probably produce an immense amount of chronic disease, and sometimes indeed speedy death. Every sample of bread—forty-nine in number—examined by Dr Hassell contained alum. Indeed the sale of "stuff" (which is a mixture of alum and salt) to the bakers is carried on on a very large scale. The object of the baker in using it is to take advantage of the affinity that it has for water, and thereby make the bread retain more water than it otherwise would, and thus give his loaves an artificial weight, and also to whiten bad and discoloured flour, and make it pass for that of superior quality. Each 4-lb. loaf contains on an average 82 grains, and a person consuming two such loaves a-week introduces into his system in that period 2 drachms and 44 grains of alum—a quantity which, as alum is a powerful astringent, must be very injurious, and which probably produces a great deal of the dyspepsia of large towns. The unnecessary quantity of salt employed by bakers is also for the purpose of retaining water amongst the bread in unnecessary abundance. The pickles sold in bottles in the shops are very bad indeed. In the first place, few of them, if we take the definition of pickle as given in the article FOOD, are pickles at all. The vegetables are greened with copper, preserved with salt and water, and packed into bottles, into which some very weak vinegar and diluted sulphuric acid are poured. Even the vegetables are not always genuine, and white cabbage is dyed to pass for red, slices of turnips made to look like cucumbers, &c. Of twenty specimens examined by Dr Hassall, the supposed vinegar never contained the proper amount of acetic acid, and in general only about half. All contained oil of vitriol, and, which is still worse, all (sixteen were tested for this purpose) salts of copper—two in small quantities only, eight in much, one in considerable, three in very considerable, one in highly deleterious, and two in immediately poisonous amount. Of the extremely injurious effects upon the health of those who daily eat these pickles thus contaminated with copper there can be no doubt. Among the symptoms produced by the continued use of cupreous preparations in small doses are paralysis, chronic inflammation of the respiratory and digestive apparatus, slow fever, and wasting of the body. The store sauces are extensively adulterated. Of twenty-eight samples of anchovy sauce, twenty-three contained Armenian bole (a ferruginous earth of a full red colour). All the samples of soy were found to consist of treacle and salt, or at least nearly so. Six out of seven bottles of tomate sauce contained colouring matter, in all cases save one Armenian bole; and a very extensively used fish-sauce contains acetate of lime and chips of charred wood. None of the sauces, however, were found to contain lead or copper. This, however, is not the case with preserves and jams, and thirty-three of these out of thirty-five that were tested were found to be adulterated with copper, and some of them in very large amount. Fruits preserved in bottles, too, nearly all had copper; and French olives in particular contained a large amount. As in preparing bottled fruits no copper utensils are employed, the poison must be deliberately added. This, too, must often be the case with preserves. Articles of sugar-confectionary are perhaps the most deleterious of all. Besides often containing sulphate of lime, which is not wholesome, the greater proportion of the colours employed are virulent poisons. Among these may be mentioned red oxide of lead, carbonate of lead, and the chromate of lead, carbonate of copper, arsenite of copper, and bisulphuret of mercury. Accordingly, from time to time, cases of virulent poisoning follow the use of these coloured articles of sugar-confectionary. (See also ADULTERATION.) (W. L. K.)

FOOLS, FEAST OF, a festival anciently celebrated on New Year's Day in churches and monasteries, particularly in France, and said to have been derived from the Saturnalia of the Romans. The extravagances and indecencies that prevailed at its celebration occasioned much scandal to the church, and various attempts were made to suppress it; but these for a long period were ineffectual, and it was not until about the fifteenth century that it began generally to fall into disuse. Many of its characteristic extravagances are still preserved in the modern carnival. (Du Tilliot, *Mémoire pour servir à l'histoire de la fête des fous.*)

FOOT. See ANATOMY, and *General Index*.

FOOT, a measure of length derived from the length of the human foot, and consisting of 12 linear inches. See MENSURATION; and for its length in different countries, see WEIGHTS and MEASURES.

FOOT, in *Prosody*, a measure consisting of certain combinations of long and short syllables. These combinations, as enumerated by the best Latin and Greek prosodians, amount in all to twenty-eight, as may be seen by the following table:

Pyrrhic	∪ ∪	Amphibrachys	∪ – ∪
Spondee	– –	Amphimacer	– ∪ –
Trochee	– ∪	Bachæus	∪ – –
Iambus	∪ –	Palimbacchæus	– – ∪
Tribrach	∪ ∪ ∪	Proceleusmaticus	∪ ∪ ∪ ∪
Molossus	– – –	Dispondæus	– – – –
Dactyl	– ∪ ∪	Ditrochæus	– ∪ – ∪
Anapæst	∪ ∪ –	Diiambus	∪ – ∪ –
Choriambus	– ∪ ∪ –	Pæon tertius	∪ ∪ – ∪
Antispastus	∪ – – ∪	Pæon quartus	∪ ∪ ∪ –
Ionicus a majore	– – ∪ ∪	Epitritus primus	∪ – – –
Ionicus a minore	∪ ∪ – –	Epitritus secundus	– ∪ – –
Pæon primus	– ∪ ∪ ∪	Epitritus tertius	– – ∪ –
Pæon secundus	∪ – ∪ ∪	Epitritus quartus	– – – ∪

By rejecting such of those feet as are merely compounds or reduplications, the number of simple feet is reduced to twelve.

FOOTE, SAMUEL, a celebrated English humourist and actor of the eighteenth century, was born of a good family at Truro, in Cornwall, in 1720. He was educated at the collegiate school of Worcester, and in his seventeenth year elected scholar of Worcester College, Oxford. During his academic career his powers of mimicry and humour began to show themselves, and were exercised with such success and indiscretion against some of the University dons, that Foote found it convenient to leave college in 1740, "without having incurred, however, any public censure." He carried away with him a very respectable amount of classical learning, and entered himself of the Temple as a student of law. But the pleasures of the town had greater attractions for him than Coke upon Lyttleton, and in a short time he had lost a handsome patrimony at the gambling-table. It is generally stated that about this time Foote married; but no traces of any such settled connection are discoverable in his career. He had two sons, indeed, but they were not born in lawful wedlock, and he used wittily to excuse his bachelorhood by saying, that "you

must count a lady's age as you do a hand at picquet, twenty-five, twenty-six, twenty-seven, twenty-eight, twenty-nine—*sixty*, and he had no ambition to awake one morning and find himself so unequally matched for the whole length of a life." Driven to the stage for support, he made his *début* in the character of Othello; but finding tragedy ill-suited to his powers, he renounced it and betook himself to comedy, in which, however, he only played with mediocre success, till he began to parts of his own writing. In 1747 he became manager of the Haymarket theatre, and succeeded in drawing large crowds by his admirable mimicry of all the social and political notabilities of the day. He kept his theatre open for many years without a patent; but he procured one at length through the influence of the Duke of York in the following manner. Riding out one day in company with that nobleman, he was thrown from his horse, and received injuries which necessitated the amputation of his leg. The Duke of York procured for him the long-withheld patent by way of compensation for the accident. The loss of his limb did not force him immediately to quit the stage, but it undermined his constitution so much that he disposed of his patent to the elder Colman, and only acted when it suited his humour. His death is said to have been accelerated by the shock he received from being obliged to stand a public trial in consequence of an infamous charge brought against him by an old servant of his own, suborned by the notorious Duchess of Kingston, whose enmity Foote had incurred by delineating her character and detailing her history in one of his comedies. In October 1777 he set out for France with the hope of there recovering his health, but death arrested his progress at Dover. He was buried in Westminster Abbey, where no memorial has yet been erected in his honour. Common consent has awarded to Foote the title of the English Aristophanes. In some respects the epithet is happy enough; in others it is little short of ridiculous. It was said of the Greek comedian that he wielded a censorship more formidable than that of the archons; it is equally true of the Englishman, that he exercised a wider jurisdiction than any chief-justice of his day. There was also a strong resemblance between the two satirists in point of wit, ready and abundant flow of humour, keen sarcasm, and above all in the audacity with which both employed their powers in bringing down laughter and scorn upon the living vices and hypocrisies of their respective eras. But Aristophanes, had he chosen to devote himself to tragedy, would have attained to as high eminence in that field as he has done in comedy. In this he shows to great advantage beside Foote, who, with comic powers as great, had neither the imagination nor the wealth of poetry of the Greek. Few of Foote's pieces are now produced on the stage. The very qualities which made him so formidable in his own day have contributed more than anything else to ensure his being forgotten in ours. His comedies, though containing admirable delineations of character, were generally *pièces d'occasion*, and are consequently devoid of that wide and general human interest which secures the immortality of an author. The whims, humours, caprices, and even persons of his own day were the subjects to which Foote was most partial. His plays are now more valuable in an historical than a dramatic point of view, and are now read chiefly by those who desire to know the spirit of social life in London during the latter half of last century.

Foote's most important plays are "*The Minor*," levelled chiefly against the Methodists; "*The Englishman returned from Paris*," which satirizes the mania for travelling. The bar is lashed in "*The Lame Lover*;" debating societies in "*The Orators*;" and newspapers in "*The Bankrupt*." Those of his pieces which kept the stage longest were "*The Liar*" and "*The Mayor of Garrat*," the humour of which is less individual than in most of his other plays. Altogether Foote is likely to be remembered by posterity rather as a social figure than as a writer or actor. As a converser he is admitted to have had almost no superior in his own day in England, except Johnson. His *bon-mots* are scarcely inferior to any in the English tongue. The personal character of Foote was in many respects very amiable. He dissipated three fortunes, of which he inherited the first and made the other two, but his heart remained as open to noble influences at the end of his career as at the beginning. He was utterly devoid of jealousy, the besetting sin of his craft; and countless instances are recorded of his generosity to obscure but meritorious actors. His friend Jewel erected a monument to his memory in Dover where he died, and inscribed on it nothing about his genius or his humour, his acting or his writing, but merely that "he had a hand as open as day to melting charity." (See *Quarterly Review*, vol. xcv., p. 483.)

FORAGE, in *Military affairs*, denotes food of any kind brought into the camp for the sustenance of the horses, &c.

FORBES, Duncan, of Culloden, one of the most honest and enlightened of Scottish patriots, was descended from the Forbeses of Tolquhoun in Aberdeenshire, a branch of whom had settled in Inverness about the end of the sixteenth century. His great-grandfather, the first northern Duncan Forbes, carried on business in the Highland capital, exchanging the native products of the country (chiefly salmon and the skins of game and cattle collected from every strath and glen) for the conveniences and luxuries to be had in England and Holland. He built ships, traded largely, and was able in 1625 to purchase the barony of Culloden from the laird of Mackintosh. He was also provost of the town, and in this capacity it fell to the lot of "Grey Duncan" (as from his flowing grey beard he was usually called) to receive the Marquis of Montrose, a prisoner, on his way from the north to Edinburgh, where shortly afterwards he was tried and beheaded. Forbes was a stern old Whig, but it appears he did not, like some others of higher rank, insult the fallen general in his misfortunes. He spread a table at the market cross, in the street through which Montrose had to pass, and covered it with wines and other refreshments, of which the prisoner partook. He accompanied him to the end of the town, and on taking leave of him courteously said, "My lord, I am sorry for your circumstances." Montrose replied, "I am sorry for being the object of your pity." (*MS. History of the Frasers.*) The incident has a touch of the picturesque romance of the old feudal times. The son and successor of Grey Duncan continued the prosperity of the family, and added to its possessions the barony of Ferrintosh in Ross-shire, and the estate of Bunchrew, a pleasant well-wooded spot on the southern shore of the Moray Frith, about three miles from Inverness. Both of these properties were purchased from the Frasers of Lovat, on whose more ancient greatness the Forbeses were now encroaching. A second Duncan Forbes inherited the strong Presbyterian Whig principles, as well as the lands of his progenitors, and was a conspicuous member of the Convention Parliament. As such, in 1689, his estates were ravaged and wasted by the Jacobite soldiery under Buchan and Cannon, and to compensate him for his losses, the Scottish Parliament granted him a privilege, always dear in the Highlands—a license perpetual to him and his heirs to distil *duty free* all the barley that might be grown in Ferrintosh. The "loyal Forbes' chartered boast," as Burns designates it, became a valuable possession. It was enjoyed nearly a century, and was withdrawn by the government in 1785, when a sum of about L.20,000 was granted as compensation. The third Duncan Forbes, afterwards Lord President, was born at Bunchrew or Culloden in the year 1685. He studied law at Edinburgh and Leyden, and was admitted advocate at the Scottish bar in 1709. His own talents, and the influence of the Argyle family, soon elevated him in his profession. At the period of the rebellion in 1715, he stood firm to the

Hanoverian cause, as did also his brother, John Forbes, then Laird of Culloden, a popular and hospitable Highland gentleman, whose convivialities are described in Burt's *Letters from the North of Scotland.* In 1722 Duncan Forbes was returned member for Inverness, and in 1725 he was appointed Lord Advocate. He succeeded to the patrimonial estates in 1734, and in 1737 he attained to the highest legal honours in Scotland, being made Lord President of the Court of Session. As Lord Advocate, Forbes had laboured to improve the legislation and revenue of the country, to spread manufactures and extend trade, and no less to render the imperial government popular and respected in Scotland. In the proceedings which followed tne memorable Porteous mob, when the government brought in a bill (which passed the Lords) for disgracing and removing the Lord Provost of Edinburgh, and for abolishing the town-guard and city gate, Forbes opposed the measure, and both spoke and voted against that paltry and vindictive outrage on the national feeling. A miserable spirit of faction and jealousy pervaded the ministry as to all just and public claims, especially on Scottish questions, while at the same time they were profuse and profligate on private and party objects. Forbes' influence abated if it could not remove this evil, and as Lord President he also carried out some legal reforms and insured the quick and impartial administration of the law. The Rebellion of 1745 found him at his post, and it tried all his patriotism. He had in vain urged upon the government the expediency of embodying Highland regiments, putting them under the command of colonels whose loyalty could be relied upon, but officering them with the native chieftains and cadets of old families in the north. Such a plan was afterwards successfully pursued by Chatham; but though Walpole is said to have approved of Forbes's scheme, the Council unanimously rejected it. Had it been adopted in time, and a few thousand pounds placed in Forbes's hands to be spent usefully in the Highlands, there would have been no Jacobite rising in '45. Through his personal influence with the chiefs of Macdonald and Macleod, those two powerful western clans were prevented from taking the field for Charles Edward; the town of Inverness he also kept loyal and well protected at the commencement of the struggle, and many of the neighbouring proprietors were won over by his persuasions. His correspondence with Lord Lovat, published in the Culloden Papers, affords a fine illustration of his character, in which the firmness of loyal principle and duty is found blended with neighbourly kindness and consideration. In the case of Lovat he had to contend with inveterate duplicity and low-minded ambition. The crafty old chief had been nearly all his life a plotter for the restoration of the Stuarts, but he would never have raised his clan had he not obtained from the Court of St Germains a commission as lieutenant-general and a patent of dukedom. This gratified his inordinate vanity and love of power. The ducal coronet, surmounting his yew-crested bonnet as chief of the Frasers, formed a vision of greatness unparalleled in the north! At this critical juncture of affairs, the apathy of the government was immovable. No advance of arms or money could be obtained until it was too late, and though Forbes employed all his own means and what money he could borrow on his personal security, his resources were quite inadequate to the emergency. And it is doubtful whether these advances were ever fully repaid. Part was doled out to him, after repeated solicitations, that his credit might be maintained in the country—his own sacrifices he did not mention, but he had fallen into disgrace in consequence of his exertions to mitigate the inhuman and impolitic severities inflicted upon the poor misguided Highlanders after their defeat at Culloden. His entreaties for mercy were heard with contempt—a brigade, it was said, would give laws! The ingratitude of the government, and the many distressing circumstances connected with this insurrection, sunk deep into the mind of Forbes. He never fairly rallied from his depression, his health declined, and he died on the 10th of December 1747, in the sixty-second year of his age. A tardy act of justice was rendered to his family. Two years after his death, a pension of L.400 per annum was granted to his only son, John Forbes; and the same good fortune that had attended the early history of his race, enabled this worthy man (the chosen associate of Thomson the poet in his youth) to free the estate from the debt so generously contracted by his father, and to add to the amount of his possessions by the purchase of contiguous lands. The fair fame of the President is, however, the proudest inheritance of his descendants. He was a patriot without ostentation or pretence—a true Scotsman with no narrow prejudices—an accomplished and even erudite scholar without pedantry—a man of genuine piety without asceticism or intolerance. His country long felt his influence through her reviving arts and institutions, and the example of such a character in that coarse and venal age, and among a people distracted by faction, political strife, and national antipathies, while it was invaluable to his contemporaries in a man of high position, is entitled to the lasting gratitude and veneration of his countrymen. In his intervals of leisure, President Forbes cultivated the study of Hebrew and biblical criticism. He was something of a speculative theologian, having embraced the views of his friend John Hutchison, the English philosopher and theological writer, that a system of natural science as well as religion could be drawn from the books of the Old Testament if interpreted according to the radical import or root of the language. In his retirement at Bunchrew—his favourite retreat—he is said to have read the Hebrew bible through eight times. His published writings are—1, A Letter to a Bishop, concerning some Important Discoveries in Philosophy and Theology; 2, Some Thoughts concerning Religion, natural and revealed, &c.; and 3, Reflections on Incredulity. His correspondence was collected and published in 1815, and a Memoir of him (from the family papers) was written by John Hill Burton, Esq., advocate, and published along with a Life of Lord Lovat, in 1847. (R. C—S.)

FORBES, EDWARD, F.R.S., F.G.S., &c., Professor of Natural History in the University of Edinburgh, was a distinguished naturalist. His range of subjects was extensive, while his consistent conduct, the candour of his disposition, the cheerfulness and amenity of his mind and manners, all added to the influence produced by the possession of great natural powers, assiduously and successfully devoted to the attainment of knowledge. So early was his admiration of natural objects developed, that he has been heard to say, that had he attempted to define the period when the love of natural history first arose as the day-star in his heart, he must have searched back into the dim and distant recollections of his earliest childhood. At this period, also, he compiled, for private use, a Manual of British Natural History, in all its branches,—a youthful labour to which he often afterwards referred with advantage.

At the age of sixteen he visited London, and while there occupied himself chiefly in the acquirement of the art of drawing, under Sass, a well-known trainer for the Royal Academy in those days. The careful practice of drawing in outline from the antique afterwards proved of great advantage to him in all his pursuits and publications. He proceeded in 1831 to Edinburgh, where he entered the medical classes. Although the study of medicine was the ostensible object of his matriculation, it was foreseen that the practice of that profession would have but few charms for one whose mind was so pervaded by the love of nature; and he in truth soon devoted himself almost entirely to the study of natural history. He became at once the friend and pupil Jameson, of whom he eventually became the successor;

and he also derived great advantage from his acquaintance with Professor Graham, whom he delighted to accompany in his botanical explorations in the Highlands of Scotland. During this youthful and energetic period, scarcely a season elapsed without some important excursion in connection with botany, or the dredging of the great waters. At the age of eighteen, with the companionship of a fellow-student, he visited Norway, from which he returned with large collections. His first public contribution to science was now made under the title of "Notes of a Natural History Tour in Norway," in the 8th and 9th volumes of Loudon's Magazine. At nearly the same period, and in the same work, he printed his earliest papers on submarine researches, "Records of the result of Dredging," a department in which he eventually became so noted.

He thus pursued his studies with great intensity of thought, yet with such radiant cheerfulness and buoyancy of spirit, as possibly to induce the belief, among those who saw not beneath the surface, that he was making less progress than others of less impulsive habit who kept upon the shady side of science. Neither did he confine himself to purely scientific matters, but mingled with these many miscellaneous exercises of a literary nature; thus strengthening and enlarging his intellectual faculties, and fitting himself all the more to take advantage of those points in the minds of younger men of the same kindly constitution, to whom a discursive power and some imaginative impulse are required to create and carry onwards their scientific tendencies. But though bold and adventurous, he was by no means fanciful. If it was by the exercise of something akin to the imaginative faculty that he foresaw and felt the grandeur of those general views, such as the graduated zones of living life, which exist not alone upon the sunny surface of the earth, but in the darksome waters far beneath it, which he was among the first to announce, it was by the most patient and oft-repeated investigations that he ascertained and combined the facts on which his final views were founded. The important law, of which he was among the earliest, as he afterwards became the most successful, exponent, is this,—that as there are great and characteristically distinct zones of animal and vegetable life *in height*, as we proceed upwards on the sides of mountains, or into alpine valleys, from the sea shore, so there are also equally distinct and different zones of animal and vegetable life *in depth*, as we proceed from that shore down the sides of sea-encircled mountains and into the great submerged and sunless valleys of the ocean.

Forbes continued to make Edinburgh his headquarters almost uninterruptedly till 1839; though he spent the greater part of 1837 in Paris, studying geology under Constant Prevost, mineralogy under Beudant, and zoology under De Blainville and Geoffroy St Hilaire. During the autumn of these several years he explored some interesting portions of Continental Europe, or beyond it, doing good service to science by a somewhat lengthened sojourn at one time in Illyria, at another in Algiers. In 1838 he visited Styria and Carniola, and published some observations on those countries in the "Proceedings of the Botanical Society," as he afterwards did an account of the fresh-water shells of Algiers and Bougia, in the "Annals of Natural History" for 1839. About the same period he published a short treatise on the mollusca of the Irish Sea, and several papers in zoology and botany.[1] In the winter of 1839 he also delivered two courses of lectures on zoology and comparative anatomy—one strictly scientific—the other of a more popular nature.

In 1841 he published his beautiful and well-known work, the "History of British Star Fishes and other Echinoderms," adorned by not fewer than 120 illustrations, all designed by himself. It may be here stated that his great artistic skill was fully and frequently employed, not only in the accurate representation of the precise forms of animal life, but also in sketches of rural and architectural scenery, and most characteristically of all in the vignettes and tail-pieces to his various works, where we have humour and sentiment very gracefully combined. In the spring of 1854 he accepted an invitation from his friend Captain Graves to join the surveying ship Beacon, then employed on the coast of Asia Minor and the adjacent islands; and having obtained a nominal appointment from the Admiralty, he joined that vessel in the capacity of naturalist. During 1841, and the following year, he pursued his researches with continuous and unabated energy, assisted by Captain Graves, who omitted no opportunity of enabling his scientific companion to accomplish all in his power. What marvel, then, that in the course of almost countless excursions with the Beacon and her boats, along the coasts of Asia Minor, and among the islands of the Ægean Sea, so rich a harvest should have been reaped. The results of their researches were made known to the public in the "Report on the Mollusca and Radiata of the Ægean Sea, and on their distribution, considered as bearing on Geology," read to the meeting of the British Association held at Cork in 1843. It appears that the data on which that report is founded were derived from eighteen months' constant researches. The calculations were based on very numerous and fully recorded dredging operations at various depths, from 1 to 130 fathoms, and in many localities from the shores of the Morea to those of Asia Minor—the chief objects being to give account of the distribution of the several tribes of mollusca and radiata in the Eastern Mediterranean, to exhibit their range in depth, and the circumstances under which they are found, to inquire into the laws which appear to regulate their distribution, and to show the general bearings of these investigations on the science of geology.

The most important result of these inquiries was the ascertainment of the almost uniform occurrence of particular species in particular zones of depth below the surface. This distribution of marine life is determined by three primary, modified by several secondary, influences. The primary influences are—climate, sea composition, and depth—the most important of the secondary agencies being the character and constitution of the sea-bottom—for according as rock, mud, sand, gravelly or weedy ground prevails, so will the number of the several genera and species vary. The form and geological construction of the neighbouring coast are also modifying features, and considerable influence is exercised by the run of tides and currents, and the influx of fresh water. The elements to be considered are therefore of a somewhat complicated nature.

Forbes gives us in this report an ample description of eight well-marked regions of depth in these eastern waters, each characterized by its own peculiar fauna, and, in such places as produce plants, by its flora. These regions are distinguished from each other by the association of the species they severally include. Certain species occur in no other, several are found in one region which do not range into the next above, whilst yet they extend to that below, or *vice versâ;* certain species have their maximum of development in each zone, being most prolific in individuals in that zone in which is their maximum, and of which they may be regarded as specially characteristic, Every zone has also a more or less mineral character, the sea-bottom not being equally variable in each, and becoming more and more uniform as we descend. The deeper zones, too, are the greater in extent, so that whilst the first or most superficial is but 12, the eighth or lowest is above

[1] For a nearly complete list of Professor Edward Forbes' writings, see *Bibliographia Zoologiæ et Geologiæ*, vol. ii., pp. 445–450.

700 feet in perpendicular range—its horizontal extent increasing in a somewhat similar proportion. Another marked and significant feature is, that as we attain to the eighth zone, the number of species, and of individuals, diminishes as we descend—thus pointing to a zero in the distribution of animal life, as yet unvisited. Species disappear in depth, which do not seem to be replaced by others; and from various observations the inference has been deduced, that the extent of the range of a species in depth is correspondent with its geographical distribution. These eight regions are themselves the scene of incessant change, for not only are the depths modified by the addition of fresh matter, but the very animals themselves, by their own increase, so alter the nature of the sea-bottom as to render it unfit for their own existence, until a new layer of sedimentary matter, uncharged with living organic contents, has formed a fresh soil for similar or other animals to thrive on. Of these observations, the high importance is obvious as explaining so many of the constantly recurring phenomena now brought under the notice of the geologist, such, for example, as the interstratification of fossiliferous and non-fossiliferous beds. The report refers to the phenomena which would be presented to us were the bottom of the Ægean Sea to be elevated and converted into dry land, or to be filled up by a long serious of sedimentary deposits, and concludes by stating that, " supposing such an elevation to have taken place, a knowledge of the association of species in the regions of depth would enable us to form a pretty accurate notion of the depth of water in which each bed was deposited. A beautiful example is given from observations made on the island of Santorin, and under different circumstances the contrary observations might be made; the geologist is thus enabled, by a careful examination of the successive overlying groups of species, to ascertain whether, in any given locality brought under his notice, the sea-bottom was being elevated or depressed."

The Beacon having visited the coasts of Lycia in the beginning of 1842, for the purpose of carrying off the remarkable remains of antiquity discovered at Xanthus by Sir Charles Fellows, her crew were employed there in making excavations among the ruins, and preparing for the removal of the marbles. For the latter task, however, the vessel proved unfitted, and while she was sent back to Malta for the necessary requirements, Forbes and Lieutenant Spratt (having been previously joined by the Rev. Mr Daniel, an accomplished draughtsman) were permitted to remain, for the sake of further antiquarian, as well as natural history, investigations. On one occasion, in company with Mr Hoskyn, the party discovered the sites of two of the Cibyratic cities; and a second excursion was still more important, as they determined the precise position of not less than eighteen ancient cities, till then unknown to geographers,—the names of fifteen being identified by inscriptions found among the ruins. During this expedition, Mr Daniel unfortunately fell a victim to the malignant malaria of the country, and Forbes himself narrowly escaped. However, he so entirely recovered as to have been on the point of setting out to prosecute his dredging operations in Egypt and the Red Sea, when the information reached him that he had been appointed to the chair of Botany in King's College, London, vacant by the death of David Don. He returned immediately to England, and delivered his inaugural lecture May 8, 1843.

A short time prior to this, Forbes had become closely connected with another important institution. On the close of 1842, Mr Londsdale, the valued curator of the museum of the geological society, resigned that situation, and Forbes was appointed in his room. But before the close of 1843, his abilities as a palæontologist introduced him into a more extended sphere of action. On the establishment of the museum of practical geology, in connection with the ordnance geological survey, under the direction of Sir Henry De la Beche, Forbes was appointed palæontologist to that new institution. On the removal of the museum to Jermyn Street, he was named its professor of natural history; and here his talents had ample scope for exercise.

Towards the conclusion of 1846 he published, in conjunction with Lieutenant (afterwards Captain) Spratt, " Travels in Lycia, Milyas, and the Cibyrates," an admirable work. About this period he gave forth also a most important contribution to geology and the sciences to which it is related, " On the connection between the Distribution of the existing Fauna and Flora of the British Isles, and the geological changes which have affected their area." In this work we have opened up to us a wide field of speculative research into almost every department of natural science, while it contains, imbedded in itself, a large and varied mass of knowledge. It throws great light on some difficult and complex inquiries regarding the age and relationship of the rocks of Britain. It affords an admirable example of the aid to be derived from other branches of natural history in the prosecution of geological researches, and of the application of animal and vegetable physiology, and a knowledge of the habits and distribution of animals and plants, in the elucidation of very difficult problems in geology. The principle or theory of this essay is based on the presumed existence of *specific centres*, or certain geographical points from which the individuals of each species have been diffused, involving their consequent descent from a single progenitor or pair, according as the sexes are united or distinct. The author is of opinion that the abandonment of that doctrine would place in a very dubious position all evidence the palæontologist could offer to the geologist towards the comparison and identification of strata, and the determination of the epoch of their formation. Having thus assumed the truth of the doctrine of specific centres, he then proposes to solve the problem of the origin of those assemblages of animals and plants which now inhabit the British Islands. Within even that limited area naturalists have recently shown that there are numerous animals and plants which are by no means universally distributed, but are congregated in such a way as to form distinct groups or provinces of life. Our vegetation, for example, exhibits five well-marked Floras, four of which are restricted to definite districts, whilst the fifth, besides exclusively claiming a portion of the area, also commingles with and overspreads the others. Forbes was of opinion, that of the three modes by which an isolated area may become inhabited by animals and plants, immigration before isolation of the area was that by which the British Isles have chiefly acquired their existing fauna and flora, terrestrial as well as marine, and that it took place subsequently to the miocene epoch. From this argument it follows, that previous to the isolation of our area, it must have been in direct union with those portions of the European continent the floras of which are shown to be identical with one or other of the five floras of the British Isles. These five distinct floras, and the districts with which he maintains they demonstrate our former connection, are as follows:—

1. *The West Irish Flora.* The high lands in the north of Spain present the nearest point where a vegetation occurs identical with that which is characteristic of the mountainous district of the west and south-west of Ireland; consequently, at some period or other, continuous dry land must have existed from the coast of Spain to that of Ireland. 2. *The Devon Flora,*—connected with that of the Channel Islands, and the neighbouring parts of France. 3. *The Kentish Flora.* The vegetation of the south-east of England is distinguished by the presence of a number of species common to this district and the opposite coast of France. 4. *The Alpine Flora.* On the tops of some of our most lofty mountains, particularly in Scotland, are

plants not found elsewhere in the British islands, but which are identical with those of the Scandinavian Alps, thus pointing to a former connection in that direction. 5. *The General Flora.* This universal flora is almost identical as to species with the flora of central and western Europe, and may properly be styled Germanic.

The distribution of marine species, both of animals and plants, is also very skilfully handled. That of the British mollusca, a favourite department, is gone into *con amore*, and a mass of information presented of great value, and at that time elsewhere unattainable. It is of great importance to the student of the tertiary geology. The author's conclusions are: That the flora and fauna, terrestrial and marine, of the British islands and seas have originated, so far as that area is concerned, since the miocene epoch: That the greater part of the terrestrial animals and flowering plants now inhabiting the British islands are members of specific centres beyond their area, and have migrated to it over continuous land, before, during, or after the glacial epoch: That all the changes, before, during, or after that epoch appear to have been gradual and not sudden, so that no marked line of demarcation can be drawn between the creatures inhabiting the same element and the same locality during two proximate periods.

For many successive seasons after this time, Forbes laboured with great assiduity, not only with pen and pencil, but in the arrangement and classification of the vast store of fossils collected by the ordnance geological surveyors, and placed in the Jermyn Street Museum. In connection with this department may here be mentioned the palæontological and geological map of the British islands, with explanatory dissertation, and the map of the "Distribution of Marine Life." In 1853 he was elected president of the Geological Society, and had scarcely occupied that chair for half the allotted time when the death of his old master, Jameson, opened up to him the professorship of natural history in the University of Edinburgh.

Professor Forbes delivered a course of lectures in Edinburgh during the summer session of 1854. He had commenced his more extended winter course when he was seized with an internal ailment from which he had previously suffered. The symptoms soon became alarming, his strength sunk rapidly, and he died, after not many days' illness, at Wardie, near Edinburgh, on the evening of Saturday, Nov. 18, 1854, in the fortieth year of his age, leaving a widow, with two infants, a son and a daughter. He was buried in the Dean Cemetery.[1] (J. W.)

FORBES, *John*, one of the most learned divines that Scotland has produced, was born May 2, 1593. He was the descendant of an ancient and opulent family: his father was Patrick Forbes, bishop of Aberdeen, his mother was Lucretia the daughter of David Spence of Wormiston. His paternal ancestor was a younger son of Lord Forbes, and he was thus connected with some of the principal families in his native district.

John Forbes, who was the second son of Patrick Forbes, after having studied at Aberdeen, was sent to the university of Heidelberg. He likewise prosecuted his studies at Sedan, and in other universities. Having devoted much time and labour to the acquisition of Greek and Hebrew, he returned to his native country in 1619, being then in the twenty-sixth year of his age, and on the 27th of April he was admitted professor of divinity in King's College, Aberdeen, where he laboured with great diligence, and acquired the character of an able and useful teacher. He was skilled in ecclesiastical antiquity; and, not content with delivering what is called a system of divinity, he exhibited a very elaborate deduction of the progress of Christian doctrine in various ages of the church. Of the value of his instructions in this department, a very adequate opinion may be formed from the perusal of a work which he published in the maturity of his learning and judgment. Nor did he neglect to instruct his students in practical religion: one division of his lectures related to moral theology, another to the pastoral care and to residence.

While he was engaged in these useful and honourable labours, the kingdom was agitated by religious dissensions. Episcopacy, commonly described by the more odious name of prelacy, was no favourite with the great body of the people; and the five articles of Perth, passed in 1618, and relating to kneeling at the communion, the observance of festivals, confirmation, private baptism, and private communion, had excited a violence of opposition with which it was found very difficult to contend. Dr Forbes, who was as much distinguished by his piety as by his learning, endeavoured to promote peaceable measures; and with this view, he published his earliest work, bearing the title of *Irenicum Amatoribus Veritatis et Pacis in Ecclesia Scoticana.*" Aberdoniæ, 1629, 4to. Of this work he sent a copy to Archbishop Usher, who received it with much cordiality. The bishop of Aberdeen did not live to witness the subversion of episcopacy: he died on the 28th of March 1635, in the seventy-first year of his age. This prelate being regarded as the restorer of the university, and as a great pillar of the church, his death was sincerely lamented by the adherents of his own party. As his eldest son had died ten years before, the professor of divinity succeeded to the family estates. Soon after the bishop's decease, a volume of 429 pages, and including a portrait, was published under the following title:—"*Funerals of a Right Reverend Father in God, Patrick Forbes of Corse, Bishop of Aberdeen.* Τοῦ ἐν ἁγίοις Reverendissimi in Christo Patris, Patricii Forbesii a Corse, Episcopi Abredoniensis, Tumulus, a multis omnium ordinum collachrymantibus variegato opere exornatus." Aberdene, 1635, 4to.

Dr Forbes, who was naturally disposed to think that nothing is better than peace,[2] next published "A peaceable Warning to the Subjects in Scotland; given in the yeare of God 1638." Aberdene, 4to. It was speedily answered in a tract ascribed to Calderwood, the most strenuous defender of the Presbyterian cause. Dr Forbes was treated with some degree of tenderness; and the Covenanters being solicitous to gain such a convert, the proceedings against him in the ecclesiastical courts were protracted for several years. After some preliminary steps, he was in 1640 cited to appear at Aberdeen before a delegation of the general assembly. He was declared to be free from the taint of popery and Arminianism; but as he still adhered to episcopacy, and declined to subscribe the covenant, his case, through the influence of Baillie, was remitted to the presbytery of Edinburgh. He was allowed a month to yield satisfaction to this judicatory, and as he failed to do so, sentence of deprivation was pronounced against him. In 1643 he moved the synod of Aberdeen to make application to the general assembly, that he might be permitted to retain his professorship without subscription; but it was there determined that his deprivation was valid from the beginning. He had purchased two houses adjoining to the college, and had assigned one of them to the professor of divinity, and the other to the *cantor*, a person on the foundation. In the deed of conveyance, he neglected to reserve to himself a liferent in the professor's house; nor can it be mentioned

[1] Professor Edward Forbes's life and labours, and lamented death, were faithfully and feelingly recorded in most of our literary and scientific journals, and in many newspapers of the day. We have made the preceding brief memoir to conform chiefly with a notice in No. 1 (for January 1855) of the *New Series* of the *Edinburgh New Philosophical Journal*, and have availed ourselves, in our geological abstracts, of some observations by W. J. Hamilton, Esq., President of the Geological Society, contained in his anniversary address. See *Quarterly Journal of the Geological Society*, May 1855.

Forbes.

without regret and indignation that he was obliged to resign it to his successor in office.

He was anxious to continue his residence in the university, for the benefit of prosecuting his researches in the public libraries; but he found that he must either subscribe the solemn league and covenant, or abandon his native country. Preferring the latter alternative, he embarked for Holland on the 5th of April 1644, and, after a voyage of five days, landed at Campvere. He travelled through the different provinces, and frequently preached in the Scottish and English churches. He had formerly married a lady of Middelburg, named Soete Roos-boom, who died on the 19th of January 1640. She was the mother of nine children; but only one of them, a son named George, was alive at the time of the father's exile. Dr Forbes resided chiefly at Amsterdam, and occupied himself in preparing for the press a work of great research and value. It appeared under the title of "*Instructiones Historico-Theologicæ de Doctrinæ Christiana, et vario Rerum Statu, ortisque Erroribus et Controversiis, jam inde a temporibus Apostolicis ad tempora usque seculi decimi-septimi priora.*" Amst. 1645, fol. A second edition followed after a considerable interval. Genevæ, 1680, fol. And an abridgment of the work was published by Arnoldus Montanus, under the title of *Forbesius contractus*. Amst. 1663, 8vo. Forbes was enabled to prefix to his ample volume the favourable judgment of the theological faculties of Leyden, Utrecht, and Franeker, as well as that of Rivet, Maresius, and Vossius. This book established the reputation of the author as a theologian of a very high rank. Bishop Burnet speaks of it as "a work which, if he had finished it, and had been suffered to enjoy the privacies of his retirement and study, to give us the second volume, had been the greatest treasure of theological learning that perhaps the world has yet seen."[1] Dr Cave has likewise mentioned it as a work of great value,[2] and it has received similar commendation from writers of many different nations.

After having resided upwards of two years in Holland, Forbes embarked at Campvere on the 8th, and arrived at Aberdeen on the 14th of July 1646. He immediately retired to his country-seat at Corse, and was permitted to spend the remainder of his days in learned and devout seclusion. He died on the 29th of April 1648, having completed the fifty-fifth year of his age. A short time before his death, he made application to the presbytery for permission to have his bones deposited in Bishop Dunbar's aisle in the cathedral church, beside those of his father and wife; but even this last favour was denied to a learned and excellent man, whose fault was a difference of opinion on the subject, not of Christian doctrine, but of ecclesiastical polity. He then directed his body to be interred in the churchyard of Leochel, where no monument was erected to his memory.[3] He left an only son, who is described by Dr Garden as the heir of his father's estates, but not of his virtues.

Dr Forbes was small in stature, and of a somewhat swarthy complexion; and, with respect to his habits of study, we are informed that he always read and wrote in a standing posture. One of the few relaxations in which he indulged was the game of golf. His conduct was upright and consistent in times of no small difficulty and distress.

An honourable monument was at length erected to his memory, in a collective edition of his Latin works. "*Reverendi viri Johannis Forbésii a Corse, Presbyteri et SS. Theologiæ Doctoris, ejusdemque Professoris in Academia Aberdonensi, Opera omnia, inter quæ plurima posthuma, reliqua ab ipso auctore interpolata, emendata atque aucta.*" Amstelædami, 1703, 2 tom. fol. The second volume bears the date of 1702. The edition is introduced by two dedications written by George Garden, D.D., an advertisement by Wetstein the printer, and a preface by Dr Gürtler, professor of divinity at Deventer. A copious life of the author, by Dr Garden, is next subjoined. Under the title of "*J. Forbesii Vita interior*," he has had added an abstract of Forbes's diary, which was written in English. One of the posthumous works is an ample treatise, entitled "*Theologiæ Moralis libri decem; in quibus Præcepta Decalogi exponuntur, et variæ circa Dei Legem, et specialia ejusdem Præcepta, Controversiæ dissolvuntur, et Casus Conscientiæ explicantur.*"

Forbes.

Forbes, *William*, bishop of Edinburgh, born at Aberdeen in the year 1585, was the son of Thomas Forbes, a respectable citizen descended from Forbes of Corsinday, whose ancestor was the second son of the same Lord Forbes from whom Forbes of Corse derived his lineage. His mother was Janet the sister of Dr Cargill, an eminent physician. From the grammar-school, where he had made unusual progress, he was at the early age of twelve removed to Mariscbal College, and there took the degree of A.M. The principal, Gilbert Gray, was so much pleased with his scholarship and modesty, that he procured his appointment to the professorship of logic. It was his duty to teach the logic of Aristotle, whom he very strenuously defended against the attacks of Ramus. This office he resigned at the expiration of four years, and afterwards prosecuted his theological studies on the Continent. Having landed at Dantzig, he travelled through a great part of Prussia and Poland. He studied in several of the universities, particularly those of Helmstädt and Heidelberg. He rendered himself familiar with the writings of the fathers and schoolmen; and in the Hebrew language he became a great proficient. After spending four years in Germany, he went to Holland, and visited the university of Leyden, where his relation Dr Jack was then a professor of philosophy; and thence he sailed for England. From London he proceeded to Oxford, where his learning was held in so much estimation that he was offered the professorship of Hebrew in that university; but his countryman Dr Craig, physician to the king, advised him to consult his health by returning to his native air; and he accordingly arrived at Aberdeen, after an absence of five years. The corporation immediately conferred upon him the freedom of the city. When his health was in some measure restored, he was appointed minister of Alford, whence he was removed to Monymusk. He soon acquired the reputation of a most eloquent preacher, and after a short interval he became one of the ministers of Aberdeen. During the king's visit to St Andrews in the year 1617, Forbes was created D.D.; and not long after, he was nominated principal of Marischal College, where he not only read lectures in divinity, but likewise taught Hebrew. After retaining the office for two years, he was induced to accept of a pastoral charge in Edinburgh, where, however, he soon discovered that his character and doctrines were held in much less estimation than in his native city. Aberdeen was the stronghold of Episcopacy, and its clergy were among the most learned and respectable of the Episcopalians; but in Edinburgh the Presbyterians were the predominant party, and Dr Forbes therefore found himself placed in a situation far from agreeable. When he already thought of resigning his living, his old friends at Aberdeen induced him to resume his spiritual labours among them, and there he continued to reside till near the close of his life. When King Charles visited Edinburgh in the year 1633, Forbes was one of those who preached before him; and the king was so much struck with his eloquence, that when he erected the new see he spontaneously nominated him as the first bishop. His patent bears the date of January 26, 1634; but he was not long permitted to enjoy his new dignity: he died on

the 11th of April, before he had completed the third month of his episcopate, and when he had only attained the forty-ninth year of his age. His remains were interred in the cathedral church of St Giles.

Bishop Forbes was a man of very extensive reading, but he did not himself publish any work. Twenty-four years after the author's death, however, Thomas Sydserf, bishop of Galloway,[1] published "*Considerationes modestæ et pacificæ Controversiarum de Justificatione, Purgatorio, Invocatione Sanctorum et Christo Mediatore, Eucharistia*, per Gulielmum Forbesium, S. T. D. et Episcopum Edinburgensem primum. Opus posthumum, diu desideratum." Lond. 1658, 8vo. The preface, subscribed T. G., that is, Thomas Gallovidiensis, is followed by an account of the author's life. This volume, which was reprinted at Helmstädt in the year 1704, attracted a very considerable degree of attention. and is mentioned by many of the continental writers.[2] The character of the learned author has thus been drawn by Bishop Burnet: "He was a grave and eminent divine: my father, that knew him long, and being of council for him in his law-matters, had occasion to know him well, has often told me, that he never saw him but he thought his heart was in heaven, and he was never alone with him but he felt within himself a commentary on these words of the apostles, 'Did not our hearts burn within us while he yet talked with us, and opened to us the Scriptures?' He preached with a zeal and vehemence that made him forget all the measures of time; two or three hours was no extraordinary thing for him; those sermons wasted his strength so fast, and his ascetical course of life was such, and he supplyed it so scantily, that he dyed within a year after his promotion; so that he only appeared there long enough to be known, but not long enough to do what might have been otherwise expected from so great a prelate. That little remnant of his that is in print shews how learned he was. I do not deny but his earnest desire of a general peace and union among all Christians has made him too favourable to many of the corruptions in the Church of Rome: but tho' a charity that is not well balanced may carry one to very indiscreet things, yet the principle from whence they flowed in him was so truly good, that the errors to which it carried him ought to be either excused, or at least to be very gently censured."[3]

FORCE, in *Philosophy*, denotes the cause of change in the state of a body, when, from being at rest, it begins to move, or has a motion which is either not uniform or not direct. While a body remains in the same state, either of rest or of uniform and rectilinear motion, the cause of its remaining in such a state is in the nature of the body, and it cannot be said that any extrinsic force has acted on it. This internal cause or principle is called *inertia*. See MECHANICS, and PHYSICS, § *Mechanical Philosophy*.

FORCEPS (Lat.), literally a pair of pincers or tongs. In surgery, an instrument for extracting things from wounds, &c. Also a pair of scissors for cutting off or dividing the fleshy membranous parts of the body.

FORCER, in *Mechanics*, a solid piston (without a valve) applied to pumps for the purpose of producing a constant stream, or to raise water to a greater height than it can be raised by the pressure of the atmosphere. See PUMP.

FORCHHEIM, a fortified town of Bavaria, circle of Upper Franconia, situated near the junction of the Wiesent with the Regnitz, 16 miles S.S.E. of Bamberg. It has a castle, a collegiate and two other churches, synagogue, monastery, hospital, and considerable trade and manufactures. In the middle ages several diets and councils of the church were held here. Pop. about 3500.

FORD, JOHN, a distinguished dramatic author, was born in 1586 at Ilsington, in Devonshire. Little is known of his personal history, but that he was educated for the bar, became a member of the Middle Temple in 1602, and continued to devote himself to his profession as a means of support while prosecuting his labours as a dramatic littérateur. His earliest efforts as a writer for the stage were in joint authorship with Dekker and Webster; but thirteen plays are understood to have been exclusively his own. The *Lover's Melancholy* appeared in 1628; the *Brother and Sister*, the *Broken Heart*, and *Love's Sacrifice*, in 1633. These were followed by the spirited historical drama, *Perkin Warbeck*. *Fancies Chaste and Noble* appeared in 1638, and the *Ladie's Trial*, which was his last work, in 1639. He is supposed to have died shortly afterwards. It is generally admitted that Ford's greatest drama is that called *'Tis Pity She's a Whore*. The unpleasant title indicates a plot still more repugnant to modern taste and feeling, embodying the development of an incestuous passion; but the poetry is of the highest order. The scenes in the *Brother and Sister*, in like manner, descriptive of the criminal loves of Annabella and Giovanni, are painfully interesting, and abound with passages of exquisite pathos and tenderness. It was usual with the old dramatists to employ their genius upon such themes as kindled the fires of passion. They lived in an age of excitement, and withdrew not themselves to study in retirement while the fierce conflict was raging around them between the newly awakened intellect and the long indulged appetites. With them the passion of love was a quenchless fire, before which the decencies of life were but as stubble; and though often wild and unnatural, it was not seldom imbued with preternatural sweetness as well as fervour. Nor even was the light of religion wholly quenched; there were glimpses of heaven in the midst of their darkest scenes of vice. Ford was pre-eminent among them for spending his poetic strength and building his reputation on unnatural and objectionable themes; but though his imagination was thus morbid, his personal deportment is said to have been by no means irregular; and Mr Hartley Coleridge suggests that it may merely have been as an exercise of intellectual power that he chose such horrible stories for his two best tragedies; and that "his moral sense was gratified by indignation at the dark possibilities of sin, and by compassion for rare extremes of suffering."

FORDINGBRIDGE, a market town of Hampshire, on the Avon, which is here crossed by a stone bridge of seven arches, 19 miles N.W. of Southampton, and 89 miles from London. It has some manufactures of sail-cloth and tickings; flax-mills; and calico-printing works. Market-day Friday. Pop. of parish (1851) 3178.

FORDUN, JOHN, the venerable father of Scottish history, apparently derived his surname from a village in the county of Kincardine, where he is supposed to have been born. He was a secular priest; and in some manuscripts of his history he is described as a chaplain of the cathedral of Aberdeen; a title which Goodall seems to have considered as equivalent to canon. Bower describes him as a simple man, who had never graduated in the schools. He was engaged in the composition of his work towards the close of the fourteenth century. The first five books, and twenty-three chapters of the sixth book of the Scotichronicon, are the composition of Fordun: for the remainder of the work in its present form, we are indebted to Walter Bower, who was born at Haddington in the year 1385, and was unanimously elected abbot of St Colm in the year 1418. This monastery, situated in a small island in the Firth of Forth, belonged to the canons regular of St Augustin. The

abbot is sometimes called Bowmaker, which is equivalent in signification to Bower. From 1395 to 1399 John Bowmaker appears as the deputy of the bailies or of the *customars* of Haddington, at the presentation of their accounts. As the first of these dates is only ten years subsequent to the abbot's birth, and as he was a native of that town, this individual might possibly be his father or other relation. At the request of Sir David Stewart of Rossyth, he undertook to transcribe the papers of Fordun; but instead of executing a mere transcript, he inserted large interpolations, and continued the narrative to the death of James the First, having thus extended the work to sixteen books. Of this continuation the principal materials had however been collected by his predecessor. Bower professes to have been careful to distinguish what belonged to each; but as the negligence of subsequent copyists has omitted all his marks, we must chiefly be guided by the internal evidence in adjusting their respective claims. The Latinity of the Scotichronicon, though certainly far from being classical, is less barbarous than that of many other chronicles of the middle ages. Winton, the author of a chronicle in Scottish verse, is perhaps a more judicious writer than either Fordun or Bower, though his share of credulity and superstition is by no means inconsiderable. Beyond this period we have scarcely any records professedly historical, except the Chronicle of Melrose, and a few other fragments, neither considerable for their value nor extent.

It would be endless, as Nicolson has remarked, "to compute into how many several chronicles this of Fordun's has been multiply'd: for, being in every monastery of the kingdom under the anonymous title of *Scoto-chronicon*, it commonly borrowed a sirname from the place to which it belong'd."[1] The Black Book of Scone, and the Black Book of Paisley, were copies which obtained no small celebrity, and which seem to have been commonly regarded as two distinct chronicles compiled in those two monasteries. Thus, the Book of Pluscardine was a copy belonging to the priory of that name. Magnus Macculloch and Patrick Russell, who are sometimes mentioned as continuators, were in all probability little more than transcribers of Fordun.

Some portions of the Scotichronicon were inserted in the collection of Dr Gale,[2] who obtained a defective copy, which he supposed to have belonged to Hector Boyce. In the year 1719, Richard Hay, a canon regular of St Augustin, issued "Proposals for Printing the Chronicle of John Fordun, with the Additions and Continuation of Walter Bowmaker, Abbot of Inch-Colm, containing the memorable things which happened in every year, since our first rise, to King James the First's death; conform to an authentick manuscript, belonging of old to one of our decay'd monasteries: with several notes, for clearing the dark parts of our history." The manuscript, "a large folio, written in old, but in glorious characters," belonged to the Cistertian monastery of St Mary at Cupar in Angus: it afterwards came into the possession of Hay, and was deposited in the Advocates' Library. He concludes his Proposals in the following manner: "Many persons of an eminent character have appeared desirous to have it printed, because what copies thereof were carried to England, France, Flanders, Italy, and elsewhere, during the heat of the Reformation, or our late disturbances, are probably lost for us. And what remain in the country, in private hands or in particular libraries, are of no use to the publick, whilst they are shut up, and as if it were hidden in obscure places, where scarce any number of men of an ordinar capacity are allowed access. Therefor I have been willing to publish this manuscript, with several notes, for the greater intelligence of our history, and a large preface, where I shall give an exact account of the fate and fortune of the most part of the others, transcribed by different hands, in former ages, with whom I have compared this original. The charges and expences of publishing this book will be certainly considerable. So those that are pleased to further and incourage this enterprize, are desired to pay ten shillings sterling at subscribing, and as much at the delivery of the printed copy, which will prove a good folio, on fine paper, and in good caracters, and will consist of 160 sheet and above. Their names and designations shall be insert in the front, and their respective houses or families shall be kindly remembered in the notes. As to the subscriptions, they are to be taken by the author, at his lodging in Howison's Land in the Potterraw; by Mr John Mackenzie of Delvin, at his lodging in the Parliament Close; by Mr Henry Massie, merchant, near the foot of Blackfriar-Wynd; by Mr William Adams, printer, over against the Trone-Church; by Mr Ruddiman in the Advocates' Library; who shall deliver to the persons concerned the author's obligation to have the compleat copy remitted to them about the end of the following year, 1720, they paying ten shillings more at the time appointed." This plan was never carried into execution; but a valuable edition was soon afterwards published by Hearne, under the title of "Johannis de Fordun Scotichronicon genuinum, una cum ejusdem Supplemento ac Continuatione." Oxon. 1722, 5 tom. 8vo. The editor proceeds upon the plan of separating the interpolations of Bower from the text of Fordun. After an interval of nearly forty years, another edition was published by Walter Goodall, assistant-keeper of the Advocates' Library: "Joannis de Fordun Scotichronicon, cum Supplementis et Continuatione Walteri Boweri, Insulæ Sancti Columbæ Abbatis." Edinb. 1759, 2 tom. fol. Goodall chiefly adheres to an excellent manuscript, written on vellum, and preserved in the library of the university of Edinburgh. (D. I.)

FORDYCE, DAVID, professor of moral philosophy in Marischal College, Aberdeen, was born in that city in 1711. Having received the early part of his education at the grammar-school, he, at the age of thirteen, entered the Greek class in Marischal College, Aberdeen; in 1728 he took the degree of master of arts, and in 1742 he was admitted professor of philosophy in the same college. Being originally designed for the church, he applied himself with great ardour to the study of divinity, in which he made great progress, though he never became a settled minister in the establishment of his native country. That he was well qualified to be such, however, appears from his *Theodorus*, a dialogue concerning the art of preaching, which he afterwards published. In 1750 he went abroad on his travels, in order to obtain fresh stores of knowledge; but after a successful tour through several parts of Europe, he was, on his return home, unfortunately cast away in a storm on the coast of Holland, in the forty-first year of his age. Besides the above work, he wrote *Dialogues on Education*, 8vo, and a Treatise on Moral Philosophy, published in the *Preceptor*. The third edition of his *Theodorus* was published in London, after his death, by his brother James, the subject of the following article.

FORDYCE, *James*, a Scottish clergyman of considerable eminence, was born at Aberdeen in the year 1720. He received his classical education at the public grammar-school, and afterwards entered Marischal College, where he went through the course of studies necessary to qualify him for being a minister of the gospel. His natural abilities were excellent; and having improved to the utmost the favourable opportunities he enjoyed at the university, he was considered as qualified for becoming a preacher of the gospel at an early period of life. His first appointment was that of second minister of Brechin, in the county of Angus, after which he accepted of a call to Alloa, near Stirling. The

[2] *Historiæ Britannicæ Scriptores XV.*, vol. i., p. 565.

people of this parish were prepossessed in favour of another, and prejudiced against Mr Fordyce, which could not fail to prove an unpleasant circumstance; yet by his impressive delivery, and indefatigable attention to every part of his ministerial duty, he soon overcame their prejudice, and acquired their esteem and admiration.

During his residence at Alloa, he attracted the notice of the public by three sermons; the first on the eloquence of the pulpit, the second on the method of promoting edification by public institutions, and the third on the delusive and sanguinary spirit of popery, preached before the synod of Perth and Stirling. But still greater admiration was excited by his sermon on the folly, infamy, and misery of unlawful pleasure, preached before the General Assembly of the Church of Scotland in 1760. About this time the university of Glasgow conferred upon him the degree of doctor of divinity, probably on account of the fame he had acquired by this sermon.

The friends of Dr Fordyce being mostly in the metropolis, he was invited to become the colleague of Dr Lawrence, minister of a respectable congregation in Monkwell Street, London, on whose death, which happened a few months afterwards, Dr Fordyce became once more celebrated for his pulpit eloquence, generally preaching to overflowing audiences. The best specimen of pulpit eloquence which perhaps proceeded from his pen was delivered at the ordination of Mr James Lindsay, who, after Fordyce declined officiating as a minister, became his successor. The remainder of his life he spent chiefly in retirement in Hampshire, in the vicinity of the residence of Lord Bute, with whom he lived on the greatest intimacy, and to whose valuable library he had unrestricted access. He afterwards went to Bath, where he suffered much from an asthmatic affection, which he bore with the fortitude of a Christian, and expired without a groan on the 1st of October 1796, in the seventy-sixth year of his age.

The Doctor's writings discover much genius and a correct taste, extensive knowledge of the world, and a happy method of engaging the attention. He was the author of *Sermons to Young Women*, 1765, in 2 vols. 12mo; *A Sermon on the Character and Conduct of the Female Sex; Addresses to Young Men*, 1777, in 2 vols. 12mo; *Addresses to the Deity*, 1785, in 12mo; *A volume of Poems; A discourse on Pain*, 1791; and *Additions to his brother's Temple of Virtue.*

Fordyce, George, a writer and lecturer on medicine, was born at Aberdeen in 1736, and studied at the university of that city, where he took the degree of master of arts at the early age of fourteen. He became apprentice to an uncle who practised surgery at Uppingham in Rutlandshire, when he was only fifteen; and afterwards went to the university of Edinburgh, where his diligence and progress attracted the attention of Dr Cullen, at that time professor of chemistry, who very generously promoted his improvement. He graduated in 1758, when only twenty-two years of age; after which he resided during one winter at Leyden. The greater part of his patrimony having been spent on his education, he resolved to try his fortune in London, where he settled in the year 1759. He commenced with a course of lectures on chemistry; and although his encouragement at first was by no means flattering, yet he steadily and diligently persevered, notwithstanding unfavourable appearances, till his literary merit began gradually to be discovered and appreciated. A number of young men who came to study in London did not think that their medical course was complete without availing themselves of the benefit of his lectures. In 1768 he published his *Elements of the Practice of Physic*, which formed the text-book of his medical course, and were much read as a valuable epitome of medicine. His private practice was very respectable; and in the year 1770 his medical reputation was so great that he was chosen physician to the hospital of St Thomas, although he had to contend against a gentleman with very powerful interest; whilst his merit as a man of science procured him admission as a member of the Royal Society in 1776. In 1787 he was chosen a fellow of the College of Physicians; and his chemical knowledge was of much importance to that body in preparing a new edition of their Pharmacopœia. By the influence of his connections, but probably more so by his literary reputation, he was appointed to furnish the navy with sour krout, which we believe he executed with advantage both to himself and to the public. By this time, however, his constitution had discovered symptoms of premature decay; yet he continued to discharge his professional duties till he fell a victim to an irregular gout, and water in the chest, on the 25th of June 1802, in the sixty-sixth year of his age. If his lectures wanted the charms of eloquent delivery, he made amends by the originality of his ideas and the extent of his scientific information. His works are, *Elements of Agriculture and Vegetation; Elements of the Practice of Physick; A Treatise on the Digestion of Food; Four Dissertations on Fever*, to which has been added a fifth, published from his manuscript since his death. His other works appeared in the *Philosophical Transactions*, to which he contributed eight papers, and in the *Medical and Chirurgical Transactions*, to which he contributed three.

FORECASTLE, that part of the upper deck of a ship forward of the foremast. Also, in merchant vessels, the forward part of the ship under the deck, where the sailors live.

FOREIGNER, the natural-born subject of a foreign state. Foreigners, though made denizens, or naturalized, are disqualified from bearing any office in government, from being of the privy council, sitting in parliament, &c. See Denizen.

FOREJUDGER, in *Law*, a judgment by which a person is deprived or put out of the thing in question.

FORELAND, North and South, two headlands on the east coast of the county of Kent. North Foreland consists of chalky cliffs nearly 200 feet in height, and has a lighthouse with a fixed light 184 feet high, and seen 24 miles off. South Foreland is about 16 miles south of the former, and has two lighthouses 1347 feet apart, and 380 and 275 feet high, visible 25 and 22 miles off.

FORE-LOCK, in nautical language, a flat wedge of iron, driven through the end of a bolt to prevent its drawing.

FOREMAST, the forward mast of all vessels.

FOREST, a large extent of ground covered with trees. The word is formed from the base Latin *foresta*, which first occurs in the capitulars of Charlemagne, and is itself derived from the German *forst*, signifying the same thing. Vossius and Spelman refer it to the Latin *foris*, as being *extra urbem et agros.*

The Caledonian and Hercynian forests are famous in history. The former was a celebrated retreat of the ancient Picts and Scots; and the latter, in Cæsar's time, extended from the borders of Alsatia and Switzerland to Transylvania, being computed at sixty days' journey in length and nine in breadth. The ancients had a superstitious veneration for forests, as being the favourite abodes of many of their gods. Temples were frequently built in the thickest forests, the gloom and silence of which were calculated to inspire sentiments of devotion. For a similar reason the Druids dwelt in forests, performing sacrifices, instructing youth, and giving laws in their umbrageous recesses.

Forest, in *Law*, is defined by Manwood, "a certain territory or circuit of woody grounds and pastures, known in its bounds as privileged for the peaceable being and abiding of wild beasts and fowls of forest, chase, and warren, to be under the king's protection for his princely delight; bounded with unremoveable marks and meres, either known by matter of record or prescription; replenished with beasts

of venery or chase, and great coverts of vert for succour of the said beasts; for preservation whereof there are particular laws, privileges, and officers belonging thereunto." Forests are of such antiquity in England that, excepting the New Forest in Hampshire, erected by William the Conqueror, and Hampton Court, erected by Henry VIII., there is no record which makes any certain mention of their erection, though they are often alluded to by various writers, and in several of our laws and statutes. Ancient historians tell us that New Forest was raised by the destruction of twenty-two parish churches, and many villages, chapels, and manors, for the space of thirty miles together, which was attended with divers judgments on the posterity of William I., who erected it; for William Rufus was there shot with an arrow, and before him Richard, the brother of Henry I.; and Henry, nephew to Robert, the eldest son of the conqueror, was, like Absalom, suspended by the hair of the head in the boughs of the forest. The Conqueror, says the 'Saxon Chronicle,'—"loved the red deer as if he had been their father;" and he is said to have visited the slaughter of one of these animals with greater severity than murder itself. This king is said to have possessed in different parts of England no fewer than sixty-eight forests, besides an immense number of chases and parks.

Legally, a forest can only be in the hands of the sovereign; for the sovereign alone has power to grant a commission to be justice in eyre of the forest. A chase differs from a forest in being capable of being held by a subject, in being of smaller extent, and subject to the common law, and not to the forest laws. A chase also may be comprised within a forest.

Forest-Laws, are peculiar laws, different from the common law of England. Before the making of the *Carta de Foresta* (granted by Henry III. A.D. 1224, and confirmed by Edward I. in 1299), offences committed in the forest were punished at the pleasure of the king in the severest manner. By this charter many forests were disforested and stripped of their oppressive privileges, and regulations were made for the government of those which remained; in particular, killing the king's deer was declared to be no longer a capital offence, but only punishable by fine, imprisonment, or abjuration of the realm. Still, in this charter there were some grievous articles, which, however, were modified by the clemency of later princes; and indeed the forest laws may now be said to be practically abolished.

FORESTALLING, in *Law*, is, by statute 5th and 6th Edw. VI., c. 14, described to be the buying or contracting for any merchandise or victual coming in the way to market; or dissuading persons from bringing their goods or provisions there; or persuading them to enhance the price when there. This, as well as *engrossing*, which is the buying up of large quantities of corn, or other dead victuals, with intent to sell them again, and *regrating*, the buying up of such commodities in any market, and selling them again in the same market, or within four miles of it, was looked upon as injurious to the public, by unnecessarily tending to raise the price of provisions; and accordingly several statutes were passed prohibiting forestalling under severe penalties. Statute 31st Edw. I. enacted that "no forestaller shall be suffered to dwell in any town who manifestly is an oppressor of the poore, a publike enemie of the whole comminaltie and countrie, who meeting grain, fish, herring, and other things coming by land or by water to bee solde, doeth make haste to buy them before other, thirsting after wicked gaine, oppressing the poore, and deceiuing the rich." By the statute of Edw. VI. already referred to, it was enacted that whoever should buy any corn or grain with intent to sell it again, should for the first offence suffer two months' imprisonment, for the second, six months' imprisonment, and forfeit double its value, and for the third, be set in the pillory, suffer imprisonment during the king's pleasure, and forfeit all his goods and chattels. This statute further enacted that no one could transport corn from one part to another without a licence, ascertaining his qualifications as a man of probity and fair dealing.

The very imperfect knowledge of political economy that then prevailed led to the belief that the intervention of a third party between the producer and consumer tended to raise the price of provisions, and that corn would be bought from the farmer cheaper than from the corn-merchant. It may seem somewhat strange that though the law thus compelled the farmer to deal directly with the consumer, yet it in many cases prohibited the manufacturer from selling his own wares by retail, in order that the shopkeepers might not be undersold. The farmer was thus forced to carry on two trades; and part of the capital which should have been employed in the improvement and cultivation of land was obliged to be kept in his granaries and stockyard: whereas the corn-merchant, by affording a ready market for the farmer's produce, enables him to employ his whole capital in cultivation; and the existence of a free competition obliges the corn-merchant to sell his corn as cheap as the farmer could afford to do. The principle here is the same as in manual labour. The workman who is wholly employed in one operation accomplishes a greater quantity of work, and can afford to do it at a cheaper rate, than one who has to carry on several operations; and, in the same way, the dealer whose whole stock is employed in a single branch of business acquires so easy and ready a method of transacting business that, with the same capital, he can carry on a much larger business, and so dispose of his goods cheaper than if his capital and attention were employed in a greater variety of objects. "If," says Adam Smith, "a merchant ever buys up corn, either going to a particular market, or in a particular market, in order to sell it again soon after in the same market, it must be because he judges that the market cannot be so liberally supplied through the whole season as upon that particular occasion, and that the price therefore must soon rise."

The rigour of the statute of Edward VI. was very much softened by subsequent statutes, which successively permitted the engrossing of corn when the price of wheat should not exceed 20s., 24s., 32s., and 48s. the quarter; and statute 12th Geo. III., cap. 71, repealed the restrictions and penalties imposed by previous statutes, which by preventing a free trade in corn and other victuals, had a tendency to discourage the growth and enhance the price of the same. This statute, however, did not declare that these offences should no longer be indictable at common law; and hence we find that when, in 1800, the price of corn rose to an unusual height, the clamour against the corn-dealers was so loud that one of the name of Rusby was indicted for the offence of regrating, though he was not brought up for judgment. It was not till the passing of the act 7th and 8th Vict., cap. 24, that the several offences of badgering, engrossing, forestalling, and regrating, were utterly taken away and abolished. It declares "that no information, indictment, suit, or prosecution, shall lie either at common law, or by virtue of any statute, or be commenced or prosecuted against any person for or by reason of any of the said offences or supposed offences."

FORFAR OR ANGUS, a county of Scotland, is bounded by the shires of Aberdeen and Kincardine on the north, the German Ocean on the east, the Firth of Tay, which separates it from Fife, on the south, and by Perthshire on the west. It is situated between 56° 27′ and 57° north latitude, and between 2° 28′ and 3° 22′ west longitude from Greenwich, and extends from north to south about 36 miles, and from east to west 27 miles. It contains, according to the agricultural statistics taken in 1854, 457,054½ imperial acres, of which 5843½ acres are let to small holders under L.10 of rent. Excluding the latter,

the acreage is occupied as follows: 89,361 in cereals, or white crop; 1601½ in beans, pease, and vetches; 32,200 in turnips; 12,530 in potatoes; 63 in mangold, carrots, and cabbage; 136 in flax; 77,350 in grass under rotation; 27,225 in permanent pasture; 106,809 in sheep walks; 69,940 waste; 26,604 woods; the remainder being occupied by houses, roads, &c. More than one-third of its area is occupied by sheep-walks and waste ground, forming part of the Grampian range, here called the Binchinnin hills, which join the Braes of Mar in Aberdeenshire. The surface of this northern division of the county, or the Braes of Angus, with the exception of the mountains at the head of Glen Clova, is not in general so bold and abrupt as many other Alpine districts in Scotland; the hills are for the most part rounded, and rather tame, and covered with a thin coat of moorish soil, bearing stunted heath. Catlaw, the highest, is 2264 feet above the level of the sea. There are several considerable valleys in this district, the principal of which are Glen Isla, Glen Prosen, Glen Esk, Clova, and Lethnot, which are watered by streams that rise in the west and north, and commonly flow south-east, receiving innumerable torrents from the mountains in their progress. South from the Grampians; and parallel to them, is another but lower range, called the Siedlaw Hills, supposed to be a continuation of the Ochils: some of these are 1400 feet in height. Between these two grand divisions lies Strathmore, the Great Valley, as the name in Gaelic denotes, or as it is commonly called the How of Angus, forming a continuation of the How of the Mearns, extending about 33 miles in length, and from six to eight in breadth; a district beautifully diversified by gentle eminences, fertile fields, plantations, villages, and gentlemen's seats, very little of it being 200 feet above sea-level. The Aberdeen and Scottish Midland Railways run along this valley, from which there are branches to Arbroath, Dundee, Kirriemuir, Blairgowrie, &c. The fourth and remaining division extends from the Siedlaw Hills to the German Ocean on the east, and the Firth of Tay on the south, and is, with a few exceptions, a rich and well-cultivated tract, varying in breadth from three to eight miles, and comprehending about a fourth part of the whole country.

The general colour of the soils in the lower districts is red, in other parts often inclining to dark brown or black. The soil in the Grampians is generally moorish over whitish retentive clay, but loose, friable, and productive in the glens. Over the pudding-stone, or farcilite rock, in the lower grounds, it is sometimes thin, mossy, and encumbered with stones, and over the sandstone a tenacious clay often occurs. The soil above whinstone is fertile, though sometimes shallow. There is no great extent of moss, the greater part of it having been drained and cultivated during the last twenty years.

The mineralogy of a considerable portion of Forfarshire was examined by Colonel Imrie, who has given a minute description of it in a paper published in the sixth volume of the *Transactions* of the Royal Society of Edinburgh. In the Grampian districts, towards the summit of the county, on the confines of Aberdeenshire, the prevailing rock is granite, some of it very beautiful, and containing in its cavities or fissures topazes and rock-crystals called cairngorms, from a mountain of that name in Aberdeenshire; also micaceous schistus, and porphyry, dykes of the latter in some places intersecting the former. Laminated mica, called by the natives *sheep's siller*, from its silvery lustre, is found in veins, in mica slate, and the rock-crystals are found in the beds of torrents. Lead was once wrought at Gilfianan, above the old castle of Invermark, in the upper part of the parish of Lochlee, and also at Ardoch, near Millden on the Esk. At the former place, according to Edward, in his *Description of Angus*, published in 1678, it yielded one sixty-fourth part of silver; but both mines have long since been abandoned. Limestone in small quantities here frequently occurs, but is now seldom or never worked. There are also broad beds of slate, but which, from some imperfections, is of little use. In descending the Grampians to Strathmore, pudding-stone prevails; and afterwards on the lower grounds, sandstone. Clay marl is found both in Strathmore and the Siedlaw hills, but is little used. Shell marl, which is the remains of myriads of small testaceous animals, is in greater request, although not so much now as some years ago: it abounds in different parts, particularly in the lochs of Kinordie, Lundie, Logie, near Kirriemuir, and Restennet near Forfar. These lochs have been partly drained, and the marl rendered of easy access. It is also found in the lochs of Forfar, Rescobie, and Balgavies, where it is raised by scoops, and conveyed to the shore in boats. The Siedlaw hills are chiefly composed of sandstone of various colours. Sandstone flags, which are much used for roofing houses, are raised in great quantities on the Hill of Balmashanner, in the moor to the south of Forfar, in the parish of Carmylie, and along the southern declivity of the Siedlaw hills. The principal lime-works are in the maritime division at Hedderwick, near Montrose, and at Boddin, in the parish of Craig. The only mineral springs worth noticing are chalybeate, one of which is near Montrose, another to the west of Arbroath, two in the side of a rivulet about a mile farther west, and one in the north-west corner of Dumbarrow, in Dunnichen parish.

The botany and zoology of the county were explored with great industry a good many years ago by Mr George Don of Forfar, who presented a very ample enumeration in both departments, in a paper subjoined to Mr Headrick's survey for the *Board of Agriculture*. A few years ago the late Mr Wm. Gardiner of Dundee, a good botanist and florist, published a small useful work on the botany of Forfarshire.

The most prevailing rains are from the east and south-east, as experienced all along the east coast of Scotland. At Crescent, half a mile westward of Dundee, the quantity of rain that fell during six years, from 1790 to 1795 inclusive, varied from 22·27 to 34·12 inches; but at Belmont, in the centre of Strathmore, during the same years, it was from 31·45 to 39·55 inches. The mean height of the barometer at Belmont during the first three of these years was 29·60°, and that of the thermometer 42°. At Crescent, the mean degree of cold during winter for the whole period was from 32½° to 39¾°, and of heat during summer, from 60½° to 66°. The south-east wind blows at Crescent 21 days, and the south-west 109 annually; whereas at Belmont the former prevails 85, and the latter 138 days. It may be interesting to add the following meteorological observations, taken with great accuracy by Mr Alexander Brown, writer, Arbroath, for the ten years inclusive from 1845 to 1854. The situation was 50 feet above the level of the sea, and about half a mile distant from it.

Barometer.

Reduced to Temperature of 32°, and Corrected.

Years.	Spring.	Summer.	Autumn.	Winter.	Mean.
1845	29·86	29·66	29·78	29·74	29·76
1846	29·75	29·58	29·72	29·93	29·74
1847	29·72	29·69	29·77	29·77	29·74
1848	29·71	29·71	29·92	29·93	29·82
1849	29·92	29·74	29·84	29·94	29·86

The above tables will assist in forming a pretty correct idea of the climate of this county, which is one generally favourable to the production of white and green crops of all kinds, and salubrious.

In addition to the lochs or lakes already mentioned, there are other two considerable ones—viz., Lochlee, among the Grampians, from which the North Esk issues, and Lentrathen near their base. This river, after leaving Lochlee, flows towards the east and then the south-east, where it forms the boundary between this county and that of Kincardine, and falls into the sea about three miles north-east of Montrose, having received in its course the Mark, the Tarf, the Westwater, the Cruik, the Luther, and other smaller streams. The South Esk rises in the north-western part of the county among the Grampian summits of Clova, and passing by Brechin, discharges itself into the basin of Montrose, after being joined by the waters of Prosen, Carrity, and other mountain and a few lowland streams. Its general course is from north-west to south-east. Isla, the last stream of any note, has also its source in the Grampians, flowing from the summit of the glen which bears its name, in a direction from north to south, until at Ruthven it bends to the westward, and joins the Tay in Perthshire. Below the Bridge of Craig it has cut a chasm, in some places more than a hundred feet in depth, through a barrier of porphyry and gravel-stone rocks, where it forms cascades of singular beauty. The Dean, the Lunan, the Dighty, and a few others, are inconsiderable streams.

Much of the landed property of Forfarshire has changed its owners within the last century; and of the forty barons mentioned by Edward in the work already referred to, the descendants of not more than a third of them now possess estates in it, and most of these are considerably reduced in size. In 1811 a large proportion of the estates were from L.100 to L.1000 a year, some from L.2000 to L.6000, and only one or two worth L.12,000 a year. At that date about a third part of the county was held under entail, but the entail act has been taken advantage of extensively in effecting either actual sales, or in placing the properties in the *fee simple* possession of the owners. The valued rent in 1674 was L.171,239, 16s. 8d. Scots. At the above date there were 266 estates, three-fourths of which were below L.500 Scots.

The real rental of the lands in 1811 was set down at L.260,196, 15s., and of the houses L.64,108 sterling. The whole number of farms was then 3222, of which about the half were under L.20 of yearly rent, and only 86 above L.300. Since that period the tendency of landowners has been to add to the size of their farms by joining smaller ones together—a policy which, in some respects, has been much questioned. The rent of lands in 1853–4 was L.295,664; of quarries, fisheries, and other property, L.7952; and the yearly value of house-property was L.278,479. Total value of real property, L.582,095. There are more than sixty gentlemen's seats, some of them venerable for their extent and antiquity, such as the castles of Glammis, Brechin, Airley, &c.; and the castles of Kinnaird and Panmure are at present undergoing such repairs and additions as will render them among the most commodious and magnificent mansions in Scotland. There is one estate that yields above L.25,000 a year, and two or three from L.16,000 to L.20,000. The farms rent from L.1500 downwards. Great improvements have been made during the last twenty years in the erection of substantial farm-houses and steadings, but very little advance has been made in supplying suitable accommodation to either married or single farm-servants. A movement has lately been set on foot, which is only a revival of one or two similar attempts formerly made to remedy this evil, but the obstacles in the way are not easily overcome. The greatest of these is, doubtless, the want of capital (and in many cases disposition conjoined) to erect proper cottages; and to supply the means necessary for this purpose, the "Agricultural Labourers' Association" does not recommend any measure of relief by loan or otherwise.

Great advancement has, of late years, been made in this county in the science and practice of agriculture, and it contains a class of tenantry nowhere exceeded in Scotland for enterprise and intelligence. The system of rotation varies according to soil and situation. The five-course shift is that most usually adopted; but as guano and artificial manures are becoming more in use, there is less land kept in grass, and more sown in green crop. Wheat, which according to Pennant was a rare crop in 1775, is now much cultivated upon almost every variety of soil, to the height of more than 1000 feet above the level of the sea; while a

very small proportion is sown with bere or bigg, which, with oats, used to be the principal white crops sown. A corresponding progress has been made in the improvement of live stock. What is usually known as the Clydesdale or west country breed of farm-horses, is common in the lower districts. The *garron* and small highland breeds, so famous for their action and durability, are now almost extinct. Last year there were 9290 saddle and work horses, of the probable value of L.300,000; and, perhaps, 2000 colts and fillies, worth L.30,000. About fifteen or twenty years ago, the Angus, a black polled breed of cattle, was almost exclusively raised. These are well known and highly valued, being in the estimation of some agriculturists of note better suited in certain respects for a northern climate than the breeds more recently introduced, especially for *feeding* purposes, by crossing with a short-horn bull. Crossing, however, has become so common during the last ten or fifteen years, that the *pure* Angus breed is not easily obtained, except from a comparatively few agriculturists who have made breeding of first-class stock a main object, the most eminent of whom is Mr Watson of Keillor. Last year there were 13,764 milk cows, 25,605 other cattle, and 10,874 calves, in all 50,243, of which 2240 belonged to tenants under L.10 of rent. The total value may be estimated at above L.500,000, being nearly double of what they were reckoned to be worth twenty years ago. The flocks of black-faced sheep are considerable; and during the last few years sheep-grazing has become general in the lowlands—the Leicester, or a cross between them and the black-faced, being most in favour. There are of ewes, gimmers, and ewe-hogs, 53,169; and of tups, wethers, and wether-hogs, 51,349, which may be valued at upwards of L.100,000. There are few or no goats worth mentioning kept. The quantity of swine fed is limited, owing to there being few or no large dairy farms. The number is 8822, of which upwards of 1000 belong to the small holders. The value of swine may be L.10,000; and the total value of live stock within the county cannot be much under L.1,000,000 sterling.

Forfarshire contains five royal burghs—viz., Forfar, the county town, Dundee, Montrose, Arbroath, Brechin, together with a number of villages, such as Kirriemuir, Glammis, &c.

The fisheries on the coast for herring, white fish, and salmon, are prosecuted with considerable success.

Many religious and military ruins are to be found in Forfarshire. Among the former, the most celebrated are the remains of the Abbey of Arbroath. This building was founded and dedicated to Thomas à Becket in 1178 by William the Lion, whose ashes repose within its walls. It was richly endowed, and has some historical interest attached to it from having, among other incidents, been the place where was held the parliament of Robert Bruce, which addressed the celebrated remonstrance to the Pope asserting the independence of the kingdom. The abbey was destroyed before the Reformation in the sixteenth century. Beside the cathedral of Brechin is a curious round tower, of which, though such be common in Ireland, only two, it is said, have been observed in Britain—this and another one at Abernethy, in Perthshire. (See Brechin.) A hill called Cater-thun, in the parish of Menmuir, north-west of Brechin, is worthy of notice. Pennant thinks it was one of the posts occupied by the Caledonians before their engagement with Agricola, at the foot of the Grampians.

There are fifty-six parishes in the county. In 1833 there were about 20,000 communicants or members of the Established Church, and about 2300 dissenters. Since that period the number of church members has greatly decreased, a large proportion of them since the Disruption having become dissenters.

Among the eminent men connected with this county may be mentioned Hector Boetius, who was born in the parish of Panbride; Archbishop Leighton and Andrew Melville, born in the parish of Craig; the Marquis of Montrose, Joseph Hume, and Sir Alexander Burnes, born in Montrose; and in Mains and Strathmartine was the residence of Grahame of Claverhouse. The county sends one member to parliament, the burgh of Dundee one, and the other royal burghs, in conjunction with Bervie, one.

Twenty years ago there was no assessment levied for the poor within the county. One half of the parishes are now assessed. Last year the number of poor on the roll was 5172, for whose support L.25,976 were expended; and there were of casual poor 1454, who received L.1165. These sums amount to more than an eleventh part of the land-rental of the county, exclusive of the sum raised by voluntary assessment.

See Edward's *Description of Angus*, reprinted in 1791, and Colonel Imrie's *Section of the Grampians*, already referred to; *Beauties of Scotland*, vol. iv.; Headrick's *General View of the Agriculture of Angus or Forfarshire; Memoirs of the Wernerian Society*, vol. ii.; *The General Report of Scotland*; Playfair's *Description of Scotland*, vol. i.; and the old and new Statistical Account of Forfarshire. (J. C—E.)

The following are the returns of the population, &c., from 1801 to 1851:—

Year.	Houses. Inhabited.	Houses. Uninhabited.	Persons. Males.	Persons. Females.	Total of Persons.
1801	..	...	45,427	53,626	99,053
1811	16,135	505	48,115	59,072	107,187
1821	16,812	576	52,036	61,319	113,355
1831	19,597	945	65,093	74,513	139,606
1841	36,184	2071	79,343	91,110	170,453
1851	22,446	725	88,324	102,940	191,264

By the computation of 1841 *flats* were reckoned *houses*.

Forfar, a royal and parliamentary burgh of Scotland, and capital of the county of the same name, in the valley of Strathmore, on the line of the Aberdeen Railway. Forfar is of considerable antiquity, having been constituted a burgh before A.D. 1261. It was at one time a residence of royalty; and in the accounts of the chamberlain of the royal household a charge is entered for the king's gardener at Forfar. The town was protected by a castle, which stood on a mound on the north side. Its origin is uncertain; but it is said by Boyce to have been the place where, in 1057, the first parliament of Malcolm Caenmore assembled after the defeat of Macbeth.

The site of this ancient fortress is now marked by a circular building of modern date. The castle, which was surrounded with water, was occupied and strongly garrisoned by the English in the beginning of the fourteenth century; but in 1307, King Robert Bruce, on his way through Angus, captured, and, as was his custom in such cases, destroyed it, after putting the English to the sword.

The weekly market was held on Sundays till 1593, when an act was passed changing the market-day from Sunday to Friday. In 1661 several parties were tried for witchcraft, and some of them burnt; and the bridle or branks put upon the head at the time of execution, is still preserved. Further, it is recorded that on September 19, 1661, "Johne Kinked, pricker of the witches in Trennent, was admittit burges and frie man" of the burgh for his services at these witch trials. Alexander Strang, provost of Forfar, was the chief opponent to the betrayal of Charles I. to the English. His name is specially mentioned in *Acta Parl.*, vol. vii., p. 615. Previous to the middle of last century the town was composed of very few two-storey houses; and notwithstanding its proximity to good gray slate quar-

ries, the houses were almost all thatched. At that time beef was not sold by weight. A leg of an ox weighing five stone could have been purchased for as many shillings, and L.2 worth served the demands of the town for a fortnight. To show the domestic condition of the inhabitants at that time, it may be stated that in this royal burgh, once the seat of royalty, there were only one or two time-pieces of any kind, and none of them patent to the public; modern luxuries, or rather necessaries, were so rare, that it could boast of only seven tea-kettles, and as many hand-bellows, while peats and wood constituted the only fuel. Since the introduction of the manufacture of "Osnaburgs" (a kind of linen), about the year 1746, the trade of the town, in various branches, has progressed rapidly. Here, as in the other towns in the county, the staple trade is the linen manufacture, which employs 2900 weavers of all kinds. The number of pieces annually produced is 104,000, comprehending 13,520,000 yards, the value of which is L.260,000. The annual revenue of the burgh is L.1527, 12s. 3d., and it is gradually increasing. There are 285 electors in the burgh, which, in conjunction with Montrose, Arbroath, Brechin, and Inverbervie, sends one member to parliament. Pop. of town and parish in 1801 was 5167; in 1841 the town population was 8362, and the landward 1258; in 1851, it was in the former 9311, and in the latter 1698. (J. C—E.)

FORFEITURE originally signifies a transgression or offence against some penal law. It is an inseparable incident to felony punishable with death, and obtains to a greater or less extent of the lands of the offender, and totally in regard to his goods and chattels. The word is formed from the base Latin *forisfactura*, whence *forfaitura* and *forfaictura*, and the French *forfait*. *Forisfactura* comes from *forisfacere*, which, according to Isidore, signifies to hurt or offend, *facere contra rationem;* and is not improbably derived from *foris*, out, and *facere*, to do, an action out of rule, or contrary to the rules. Borel thinks *forfait* is derived from the using of force or violence; and Lobineau, in his glossary, supposes *forisfacta* properly to signify a mulct or amend, not a *forfeit*, which latter he derives from the Bas-Breton *forfed*, a penalty. But with us it is now more frequently used for the effect of such transgression, as the losing some right, privilege, estate, honour, office, or effects, in consequence thereof, than for the transgression itself. Forfeiture differs from confiscation in this, that the former is more general; whilst confiscation is particularly applied to such things as become forfeited to the king's exchequer; and goods confiscated are said to be such as nobody claims. See ATTAINDER, TREASON.

FORFICULA, the Earwig, a genus of coleopterous insects. See index to ENTOMOLOGY.

FORGE, a furnace where wrought iron or other metal is hammered and fashioned with the aid of heat. This is called a smith's forge. In ships a very convenient kind is the portable truck forge. Forge is also applied to the blast furnace, in which iron ore is smelted; also, where the production of the blast furnace is fused, and afterwards beaten with enormous hammers, or drawn through cylinders of different diameter, in order to render the metal soft, pure, and more malleable and ductile. Such great workshops are otherwise called *shingling mills*. See IRON-MAKING.

An ordinary smith's forge consists of the hearth or fireplace, which is merely a cavity in masonry or brick-work, lined with fire-clay or brick, and containing ignited fuel, upon which a powerful blast of air is driven through the nozzle of double-bellows, worked by a hand-lever. There are also portable forges, of small dimensions, but answering all the ordinary purposes of a smith's forge. Such are the travelling forges of armies, those used on board ships, &c.

FORGERY (from the French *forger*, signifying *accudere, fabricare*, to beat on an anvil, forge, or form), may be defined at common law to be the fraudulent making or alteration of a writing or seal, to the prejudice of another man's right; or it is the crime of imitating the subscription of another, adhibiting it to a deed, and putting that deed to use by acting under it, receiving property in virtue of it, founding on it as a title to sue or to defend, or transferring it to another. In considering forgery, it is necessary to attend, first, to the mode of proof by which the crime is established; and, secondly, to the punishment which is inflicted on the perpetrator thereof.

The proof of forgery is either direct or indirect. The direct proof consists in the examination of the writer of the deed, and of the witnesses who sign the deed and attest the subscription. As the subscription of witnesses is an attestation to which the law gives effect to the extent of receiving it on their death as evidence of the regularity of the deed, and as weight is given to the subscription of a witness, even where he does not recollect having adhibited it; so, to cut down a deed regularly attested, the instrumentary witnesses, as they are called in Scotland, must be brought to swear to circumstances of sufficient force to invalidate the evidence given by their subscriptions; a species of proof which the law does not and indeed cannot reject. The indirect mode of proof consists in an investigation of all the circumstances from which it may be inferred that the person by whom a deed is said to have been executed actually did not subscribe; as, for instance, an error in the date, an *alibi*, the stamp, the contexture of or date impressed upon the paper, or a *comparatio literarum*. The comparison of the handwriting is made with genuine subscriptions of the same date as that alleged to have been forged; and where the real subscriptions differ materially from the one founded on, the forgery of the latter may be pronounced on with a considerable degree of certainty. It is an established rule, however, that the proof of forgery by a mere comparison of handwriting is not admissible.

Until recently the punishment of forgery was not expressly laid down by statute; but by the common law and practice of the country, conviction was usually followed by a capital punishment in all cases of gross forgery; whilst those of less moment, as forgeries of executions, or where the evidence was not in every respect conclusive, were commonly visited with what in Scotland is denominated an arbitrary punishment, that is, with imprisonment or transportation. At length, however, the severity of the law in this particular was considerably mitigated, and the punishment of death restricted to the cases of forgery enumerated by the 11th Geo. IV. and 1st William IV., cap. 66. Afterwards by the 2d and 3d William IV., cap. 123, entitled an "act for abolishing the punishment of death in certain cases of forgery," it was enacted, that where any person shall thereafter be convicted of any offence whatsoever for which the previous act of William IV. enjoins or authorizes the infliction of the punishment of death, or for any offence which shall consist wholly or in part of forging or altering any writing, instrument, matter, or thing whatsoever, or of offering, uttering, or disposing of any writing, instrument, matter, or thing whatsoever, knowing the same to be forged or altered, or of falsely personating another, such offender shall not suffer death, or have sentence of death awarded against him, but shall be transported beyond the seas for the term of such offender's life. But it is at the same time specially provided that nothing in this act shall be construed to extend to the forging or altering, offering, uttering or disposing of, knowing the same to be forged or altered, any will, testament, codicil, or testamentary writing, with intent to defraud any body corporate or person whatsoever, or of forging or altering, or of uttering, knowing the same to be forged or altered, any power of attorney or other authority to transfer any share or interest in any stock, annuity, or other public fund, transferable at the Bank of England or South-Sea House, or Bank of Ireland, or to receive any

dividend payable in respect of such share or interest, with intent to defraud any body corporate or person whatsoever, or of procuring, aiding, or assisting in the commission of such offences, for all which offences the punishment of death is to continue the same as if this act had not been passed. And further, by 3d and 4th William IV., cap. 44, it is enacted, that persons punishable with transportation for life under the act of 2d and 3d William IV., shall be liable, previously to their being transported, in case the court before which they are convicted shall think fit, to be imprisoned, with or without hard labour, in the common gaol or house of correction, or to be confined in the penitentiary for any term not exceeding four years nor less than one. And, lastly, by the 7th William IV. and 1st Vict., cap. 84, the punishment of death was abolished in all cases of forgery, and the punishment substituted of transportation for life, or not less than seven years, or imprisonment for not exceeding four nor less than two years, with or without hard labour and solitary confinement, if the court think fit. As it formerly stood its excessive severity had rendered it to a certain extent inoperative; for as the natural feelings of mankind revolt at the indiscriminate sacrifice of human life for offences of a secondary description, judges and juries had tacitly combined to evade giving it effect in the less aggravated class of cases, and thus to reconcile with public opinion the practical administration of justice in this particular. From this mitigation which has taken place the efficacy of the law has been augmented by increasing the certainty of the punishment it awards; and a diminution in the number of offences of this kind resulted, which the excessive but irregular severity of the law, as it formerly stood, had failed to produce.

FORGING, in *Smithery*. See FORGE, and IRON-MAKING.

FORIS, a seaport-town of Naples, on the W. coast of the island of Ischia. It has a good harbour and some trade, and several hot springs in the vicinity. Pop. about 5000.

FORISFAMILIATION, in *Law*. When a child, upon receiving a portion from his father, or otherwise, renounces his legal title to any further share of his father's succession, he is said to be *forisfamiliated*.

FORK, a well-known instrument, consisting of a handle and a shaft terminating in two or more points or prongs. The *table-fork* did not come into use in England till the reign of James I., as we learn from a remarkable passage in Coryat, who thus solemnly relates the history of its introduction: "Here I will mention a thing that might have been spoken of before in discourse of the first Italian townes. I observed a custom in all those Italian cities and townes through the which I passed, that is not used in any other country that I saw in my travels, neither do I think any other nation of Christendome doth use it, but only Italy. The Italians, and also most strangers that are commorant in Italy, doe always at their meals use a little forke when they eat their meate; for while with their knife, which they hold in one hand, they cut the meate out of the dish, they fasten the forke, which they hold in the other hand, upon the same dish, so that whatsoever he be that sitting in the company of any others at meale shall unadvisedly touch the dish of meate with his fingers from which all the table doe cut, he will give occasion of offence unto the company as having transgressed the lawes of good manners, insomuch that for his error he shall be at least browbeaten, if not reprehended in wordes. This form of feeding, I understand, is generally used in all parts of Italy, their forkes for the most part being made of yronn, steele, and some of silver, but those are used only by gentlemen. The reason of this their curiosity is, because the Italian cannot by any means indure to have his dish touched with fingers, seeing all men's fingers are not alike cleane. Hereupon I myself thought good to imitate the Italian fashion by this forked cutting of meate, not only while I was in Italy, but also in Germany, and often times in England since I came home: being once quipped for that frequently using my fork, by a certain learned gentleman, a familiar friend of mine, Mr Lawrence Whitaker, who in his merry humour doubted not to call me a table *furcifer*, only for using a forke at feeding, but for no other cause."

FORKEL, J. NICHOLAS, a German musician and musical historian, was born at Meeder (in Saxony) in 1749. He was appointed "Director of the Music" in the University of Göttingen. His works are: *A General History of Music*, in 2 vols. 4to; *A General Biography of Musicians;* and *The Critical Musical Library*, in three vols., published at Leipzig. The best of his works is the "General History of Music," which is still considered in many parts of Germany as a standard work. He died in 1818.

FORLI, the ancient *Forum Livii*, a city of Italy, capital of a cognominal legation in the Papal States, is situated at the foot of the Apennines, in a pleasant and fertile plain, watered by the Ronco and the Montone, 38 miles S.E. of Bologna. It stands on the Æmilian way, and is surrounded by old walls, which however are of little use as a means of defence. The town is handsome and well built, and the streets are adorned with arcades. It has a fine square, a cathedral, several elegant palaces, a city hall, and other public buildings. It carries on a considerable trade in agricultural produce, and has manufactures of silk ribands and twist, oil-cloth and woollen fabrics, and wax, salt, and nitre refineries. Forli is said to have been founded by Livius Salinator after the defeat of Hasdrubal. During the middle ages it became a place of some importance; and in the fifteenth century the citadel (now used as a prison) was nobly defended by Catherine Sforza. In 1797 it was taken by the French, and made the capital of the department of the Rubicon, but in 1815 it was restored to the Pope. Pop. about 16,000.

FORLORN HOPE, in military affairs, the body of picked men guided by engineer officers, detached to lead the assault, or storm a fortress, or to perform any service attended with great danger and peril. The term is synonymous with the French *enfans perdus*.

FORM, in *Physics*, denotes the manner of being peculiar to each body; or that which constitutes it such a particular body, and distinguishes it from every other. But Mr Harris uses the term *form* in another sense, as an efficient animating principle; to which he supposes Ovid to refer in the first lines of his Metamorphoses:—

> *In nova fert animus mutatas dicere* formas
> *Corpora.*

These animating forms are not of themselves objects either of the ear or of the eye; but their nature or character is understood in this, that were they never to exert their proper energies on their proper subjects, the marble on which the sculptor exercises his art would remain for ever shapeless, and the harp from which the harper calls forth sounds would remain for ever silent.

Substantial forms seem to have been first broached by the followers of Aristotle, who thought matter, under different modes or modifications, not sufficient to constitute different bodies, but that something substantial was necessary to set them at a greater distance, and thus introduced substantial forms, on the footing of souls, which specify and distinguish animals. What led to this erroneous notion were the circumstances of life and death. For observing that, as soon as the soul had departed out of a man, all motion, respiration, nutrition, and other animal functions, immediately ceased, they concluded that these functions depended on the soul, and consequently that the soul was the form of the animal body, or that which constituted it such; indeed nobody doubted that the soul was a substance independent of matter; and hence it was concluded that the forms of other bodies were to be equally substantial. But

to this it is answered, that though the soul be that by which man is man, and consequently the form of the human body as human, yet it does not follow that it is properly the form of this body of ours, as it is a body, or of the several parts thereof, considered as distinct from one another. For those several parts have their proper forms so closely connected with their matter, that it remains inseparable therefrom long after the soul has quitted the body; thus flesh has the form of flesh, bone of bone, and so forth, long after the soul is removed, as well as before. The truth is, the body does not become incapable of performing its accustomed functions because the soul has deserted it; but the soul takes its departure because the body is no longer in a condition to perform its functions.

The ancient and modern corpuscular philosophers, therefore, with the Cartesians, exclude the notion of substantial forms, and show, by many arguments, that the form is only the *modus* or manner of the body in which it is inherent. And as there are only three primary modes of matter, figure, rest, or motion, with two others arising therefrom, magnitude and situation, the form of all bodies they hold to consist in these modes, and suppose the variations which they are capable of sufficient to present all the variety observable in bodies.

Forms are usually distinguished into *essential* and *accidental*. Though the five modes above mentioned, generally taken, be adventitious, yet to this or that body, as to fire or water, they are *essential*. Thus it is *accidental* to iron to have this or that magnitude, figure, or situation, since it might exist in different ones; yet to a knife or hammer, the figure, magnitude, and position of parts, which constitute it a hammer or knife, are essential, and they cannot exist or be conceived without these. Hence it is inferred, that though there be no substantial, yet there are essential forms, by which the several species of bodies become what they are, and are distinguished from all others. *Accidental* forms are those really inherent in bodies, but in such manner as that the body may exist in all its perfection without them; such as whiteness in a wall, heat in water, &c.

FORMALITY, as defined in the scholastic philosophy, is the manner in which a thing is conceived; or a manner in an object importing a relation to the understanding, by which it may be distinguished from another object. Thus animality and rationality are formalities. The Scotists made great use of formalities, in opposition to the virtualities of the Thomists.

FORMALITIES, in matters of law, are frequently used for the formulæ themselves, or the rules prescribed for judicial procedure. In contracts of strict law all the formalities must be strictly observed, as an omission of the least may ruin the whole convention.

FORMAN, ANDREW, archbishop of St Andrews, Earl of Pittenweem, and of Cottingham in England, one of the lords of the regency appointed by the states during the minority of King James V. of Scotland, legate *a latere*, primate of all the kingdom of Scotland, and archbishop of Bourges in France, was descended from the family of the Formans of Hutton in the county of Berwick, and is considered as having been one of the best statesmen of the age in which he lived. He was employed in 1501, along with Robert Blackader, archbishop of Glasgow, and Patrick earl of Bothwell, to negotiate a match between James IV. of Scotland and Margaret, eldest daughter of Henry VII. of England, which next year was ratified by the Scottish ambassadors. He was afterwards frequently employed as Scottish ambassador to Rome, England, and France, upon the most important occasions. In 1514 he was translated from the see of Moray, to which he had been appointed in 1502, to that of St Andrews. During the time he possessed the former, he was employed as mediator between Pope Julius II. and Louis XII. of France, who were at that time at variance; and he happily succeeded in conciliating the difference. Having taken leave of the pope, he on his return home passed through France, where he was kindly received by the king and queen, who bestowed upon him the bishopric of Bourges in France, which brought him annually 400 tuns of wine, 10,000 francs of gold, and other smaller matters. Besides this, he was most liberally rewarded by Pope Julius, who promoted him to the archbishopric of St Andrews, as has been already mentioned, conferred on him the two rich abbeys of Dunfermline and Aberbrothick, and made him his legate *a latere*. At that time, however, there were two other candidates for the archiepiscopal see. The learned Gavin Douglas, bishop of Dunkeld, having been nominated by the queen, had actually taken possession; but John Hepburn, a bold and factious man, having been preferred by the monks, drove out the officers of Gavin Douglas, and placed a strong garrison in the castle. And so great was the power of this man, that when Forman was nominated by the pope, no person could be found to proclaim the bulls for his election. At last Lord Home, at that time the most powerful nobleman in Scotland, was induced, by large promises, besides some considerable gifts, amongst which was the donation of the abbacy of Coldingham to his youngest brother David, to undertake the task. It was executed at Edinburgh and at St Andrews, to which places Lord Home's brother proceeded with 10,000 men; though the doing of it, contrary to Forman's inclination, proved a source of much trouble to that nobleman afterwards. The quarrel between Hepburn and Forman, however, was at last terminated by the latter surrendering the bishopric of Moray, as well as some years' revenue of the archbishopric itself, and paying Hepburn three thousand French crowns annually out of his ecclesiastical revenues. On the appointment of the Duke of Albany to the regency, Hepburn endeavoured to undermine the primate's credit with that nobleman, by representing him as one who had in a manner collected all the money in the country, and who consequently might endanger the tranquillity of the kingdom. These insinuations, however, were but little regarded by the regent; and Forman had the good fortune afterwards to compose a difference between him and the nobility, which was likely to be attended with bloodshed. In 1517 the archbishop was appointed by the states one of the lords of the regency, on the occasion of the Duke of Albany's going to France. His embassy to Pope Julius II. has been already mentioned. In Mackenzie's Lives we are informed, that in the collection of the Letters of the Scottish Kings from the year 1505 till the year 1626, in the Advocates' Library, there is a letter from the pope to King James IV., in which he not only commends Forman highly, but likewise promises that at the first creation of cardinals he should be made one. This letter is dated the 6th of May 1511; but the pope died before he had an opportunity of performing his promise. In the same collection there is a letter from the Duke of Albany to Leo X., successor of Julius, in which he urges the pope to advance Forman to the dignity of a cardinal, promised him by his predecessor, and to continue him as legate *a latere*. Archbishop Forman died in the year 1521, and was buried at Dunfermline. Dempster says that he wrote a book against Luther, a book concerning the Stoical philosophy, and a collection out of the Decretals.

FORMEDON, in *Law* (*breve de forma donationis*), a writ that lies for a person who has a right to lands or tenements by virtue of any entail, arising from the statute of Westminster.

FORMENTERA, the ancient *Ophiusa* or *Pityusa Minor*, one of the Balearic Islands belonging to Spain, and lying 3 miles S. of the island of Iviça. It is about 13 miles in length, by from 2 to 10 in breadth, and takes its name from the abundant crops of wheat raised in the western part,

the eastern part being chiefly covered with wood. It contains no town, and the inhabitants, amounting to about 1500, live in villages or detached cottages.

FORMIÆ (now *Mola di Gaëta*), a city of Latium, near the Via Appia, on the innermost recess of the Sinus Caietanus, or Gulf of Gaëta. It was founded very anciently by the Tyrrhenians. Some of the later poets supposed the city of Lamus, which Homer mentions, to be the same as Formiæ. At an early period Formiæ received the Roman franchise and became a municipium. Villas were built at this spot by many of the noble Romans who were attracted by the rich beauty of the surrounding country. The villa of Cicero may still be seen near Castiglione at the villa Marsana, the furthest of the three from Mola. The vine of the Formian hills produced excellent wine in the time of Horace.

FORMICA, the ANT. See index to ENTOMOLOGY.

FORMOSA (Chinese *Taewan*, i.e. *Terrace Beach*), an island lying about 90 miles off the coast of China, from which it is separated by the channel of Fo-kien. It is about 250 miles in length from N. to S., and 80 in breadth, lying between N. Lat. 22. and 25. 30., and E. Long. 120. 30. and 122. A volcanic mountain chain, rising to the height of upwards of 12,000 feet, traverses the centre of the island from N. to S., and separates the Chinese portion of it on the W. from the independent portion on the E. Some parts of the coast present bold headlands; but all the W. shore is flat and surrounded with rocks and quicksands, presenting no good harbours, with the exception of Kélung at its northern extremity. The Chinese portion of it is fertile and well watered, and possesses a very salubrious climate. Almost all grains and fruits may be produced on some part of the island, which is familiarly known as the granary of the maritime provinces of China. The rice trade alone with these provinces employs more than 300 vessels. Among its other articles of trade are maize, tobacco, sugar, fruits, timber, salt, sulphur, camphor, cotton, hemp, silk, &c. Of the eastern portion of the island little is known; the inhabitants bear no resemblance to the Chinese, but are apparently allied to the Malay or Polynesian tribes. They are of a slender form, olive complexion, wear long hair, and blacken their teeth. They have no written language, and their religion seems to be confined to a superstitious belief in demons and sorcerers. Many of the aboriginal inhabitants are still to be found on the western portion of the island, living in independent villages; others however have become incorporated with the Chinese settlers, or live in villages of their own, under the general supervision of Chinese officers.

Formosa was unknown to the Chinese till about 1403. About 1634 the Dutch established themselves here, and built Fort Zealand on a small island commanding the harbour of the capital Taewan. After retaining possession of it for 28 years, they were expelled by the famous Chinese rebel Coxinga, whose successors ruled in the island till 1683, when it was taken by the Chinese. Taewan, the capital, stands on the W. coast in N. Lat. 23. E. Long. 120. 32; but the entrance of its harbour is now choked up. The population of Formosa is estimated at from 2,000,000 to 3,000,000.

FORMULA, or FORMULARY, a rule or model, or certain terms prescribed or decreed by authority, for the form and manner of an act, instrument, proceeding, or the like.

In *Church affairs*, a profession of faith. In *Medicine*, the constitution of medicines, either with respect to their prescription or their consistence. *Chemical Formulæ* are symbols representing the different substances, simple and compound.

FORMULA, in *Mathematics*, a theorem or general rule or expression, for solving certain particular cases of some problem; so $\frac{1}{2}s + \frac{1}{2}d$ is a general formula for the greater of two quantities whose sum is s, and difference d; and $\frac{1}{2}s - \frac{1}{2}d$ is the formula or general value for the less quantity. Also $\sqrt{ax - x^2}$ is the formula or general value of the ordinate to a circle whose diameter is a and absciss x.

FORMULARY, a book or writing containing stated and prescribed forms, as of oaths, declarations, prayers, and the like; a book of precedents; a prescribed form in anything.

FORNACALIA, in *Roman Antiquity*, a festival instituted by Numa, in honour of Fornax, the goddess of ovens, at which certain cakes were offered in sacrifice. Hartung identifies Fornax with Vesta.

FORNAX, a constellation. See ASTRONOMY.

FORNIX, in *Anatomy*, a part of the *corpus callosum* in the brain, so called from its somewhat resembling a Gothic arch in shape when viewed in a particular direction.

FORRES, a royal and parliamentary burgh of Scotland, county of Moray, situated on a rising ground three miles S. of Findhorn, its port at the mouth of the river of the same name. It is a neat and well-built town, surrounded by scenery of great beauty. The great road to Inverness forms its main street, from which several smaller ones branch off. It possesses an excellent academy, called the Anderson Institution (from its founder, a private gentleman of that name), in which the classics, mathematics, natural philosophy, and other branches are taught. Besides this academy there are several private schools; also a newsroom, subscription library, and various friendly societies. Besides the parish church, there are a Free Church, and chapels for Episcopalians, United Presbyterians, and Independents. On a hill W. of the town are some remains of the ancient castle of Forres; and on another eminence in the vicinity a tower in memory of Nelson has been erected. Forres unites with Inverness, Nairn, and Fortrose, in returning a member to parliament, and is governed by a provost, three bailies, and thirteen councillors. Pop. (1851) of municipal burgh 3339, of parliamentary burgh 3468. Forres is noted for the possession of one of the most remarkable ancient stone obelisks to be found in Britain. It is thus described by Mr Cordiner, in a letter to Mr Pennant: "In the first division, underneath the Gothic ornaments at the top, are nine horses with their riders marching forth in order. In the next is a line of warriors on foot, brandishing their weapons, and in the act of shouting for the battle. The import of the attitudes in the third division is very dubious, their expression indefinite. The figures which form a square in the middle of the column are pretty complex, but distinct; four serjeants with their halberts guard a canopy, under which are placed several human heads which have belonged to the dead bodies piled up at the left of the division; one appears in the character of executioner severing the head from another body; behind him are three trumpeters sounding their trumpets, and before him two pair of combatants fighting with sword and target. A troop of horse next appears, put to flight by infantry, whose first line have bows and arrows, the three following swords and targets. In the lowermost division now visible, the horses seem to be seized by the victorious party, their riders beheaded, and the head of their chief hung in chains or placed in a frame; the others being thrown together beside the dead bodies under an arched cover. The greatest part of the other side of the obelisk, occupied by a sumptuous cross, is covered over with an uniform figure, elaborately raised, and interwoven with great mathematical exactness. Under the cross are two august personages, with some attendants, much obliterated, but evidently in an attitude of reconciliation; and if the monument was erected in memory of the peace concluded between Malcolm and Canute, upon the final retreat of the Danes, these large figures may represent the reconciled monarchs. On the edge below the fretwork are some rows of figures joined hand in hand, which may also imply the new degree of confidence and security which

took place, after the feuds were composed, which were characterized on the front of the pillar. But to whatever particular transaction it may allude, it can hardly be imagined that, in so early an age of the arts in Scotland as it must have been raised, so elaborate a performance would have been undertaken but in consequence of an event of the most general importance; it is therefore surprising that no distincter traditions of it arrived at the era when letters were known. The height of this monument (called *King Sueno's Stone*) above the ground is 23 feet, besides 12 or 15 feet under ground. Its breadth is 3 feet 10 inches by 1 foot 3 inches in thickness."

FORSKAL, Peter, a celebrated oriental traveller and naturalist, was born in Sweden in 1736. He studied at Göttingen, where he published a dissertation entitled *Dubia de Principiis Philosophiæ Recentioris*, which is considered a creditable production. Thence he returned to his own country, and in 1759 he wrote *Pensées sur la Liberté Civile*, a pamphlet which the rulers of Sweden highly disapproved of. At this time Linnæus was in the zenith of his fame; and Forskal, through his fondness for natural history, became acquainted with the great naturalist, who recommended him to Frederic V. of Denmark. Here, after obtaining the title of professor at Copenhagen, he was appointed to accompany Niebuhr in an expedition to investigate the antiquities of Arabia and Egypt. But his career was cut short by death at Jerim, July 11, 1763. Though his time was short, and his difficulties very great, yet his account of the vegetation of Egypt and Arabia is a model of the method in which such investigations should be prosecuted. His friend and companion Niebuhr was entrusted with the care of editing his MS., from which he produced a Fauna Orientalis, entitled *Descriptiones Animalium, Avium, Amphibiorum, Piscium, Insectorum, Vermium, quae in itin. orient. observavit Petrus Forskal.* 1775, 4to. In the same year appeared also an account of the plants of Arabia Felix and of Lower Egypt, under the title of *Ægyptiaco-Arabica.* This work is far in advance of those of the same nature produced by the adherents of Linnæus; and is especially remarkable as being one of the first works in which the importance of the relation of vegetation to climate is fully appreciated. By the remarkable assertion that "the specimens of plants being given, the latitude, the elevation of the surface, and the zones of vegetation upon the mountains of a country may be found," Forskal laid the foundation of geographical botany, which has proved of such interest and importance in the hands of Humboldt and other recent scientific travellers.

FORSTER, John Reinhold, a celebrated naturalist and geographer, and an accomplished scholar and linguist, born Oct. 22, 1729, at Dirschau in Polish Prussia, where his father was burgomaster or mayor. His family was of English descent, and had quitted Great Britain in the time of Charles I. At the age of fourteen he was placed for a year at the public school of Marienwerder, and was afterwards admitted into the gymnasium of Joachimsthal at Berlin, where among his schoolfellows was Pallas the celebrated naturalist. Forster applied with diligence to the study of the ancient and modern languages, and in particular of the oriental languages; and he continued the same pursuits at the university of Halle, which he entered in 1748. After three years, having completed his theological studies, he resided for two years more at Danzig, preaching as a candidate. In 1753 he obtained a small benefice at the neighbouring town of Nassenhuben; and the next year he married his cousin Elizabeth Nikolai. The expenses of his increasing family induced him to accept the proposals of the Russian consul at Danzig to superintend the establishment of the new colonies at Saratof on the Volga; but Forster, not satisfied with his success in the undertaking, in 1766 resolved to try his fortune in England, hither he proceeded well recommended but with exhausted finances. Soon afterwards, however, he received a gratuity of 100 guineas from the Russian government, and he obtained some remuneration from the booksellers for his translations from the German and the Swedish. He declined an offer of Lord Baltimore to manage his estates in America, preferring the appointment of a teacher of modern languages and natural history in the dissenting academy of Warrington. He was not, however, very popular as an instructor. In 1772 he was appointed naturalist to the expedition under the command of Captain Cook, in his second voyage of circumnavigation; and he took with him his son George, then seventeen years old. For this undertaking Forster was abundantly qualified as a man of science and an accurate observer, though his temper and conduct were not always such as to make him agreeable to his shipmates, nor was he uniformly considerate and humane in his intercourse with the uncivilized inhabitants of the countries he explored. After the return of the expedition, there were repeated disputes respecting Forster's share in the intended publication of the narrative of the voyage. Two thousand pounds, which had been granted by government for the plates of the work, were to have been equally divided between Cook and Forster for this purpose; but Forster's performance of his part of the undertaking was disapproved, and he was deprived of the advantage which he expected to have derived from the plates. He was supposed to be concerned in the account of the voyage which was published by his son; and this participation was generally considered as an infringement of the conditions of his engagement; besides that many offensive remarks and a few inaccuracies were introduced into the work. All these circumstances made Forster's residence in England by no means agreeable, and his pecuniary embarrassments became so pressing that he was at one time in confinement for debt. He was, however, set at liberty in 1780, by the munificence of the king of Prussia, who paid his debts and established him at Halle as professor of natural history, and inspector of the botanical garden. The following year he took the decree of M.D. in the university. He was not always on the most cordial terms with his academical colleagues, and his circumstances were also much embarrassed by his unfortunate propensity to play, which absorbed his whole earnings. The premature death of his two sons seriously affected his health, and he died on the 9th December 1798. His life has been written by Professor Kurt Sprengel, but in a manner somewhat too flattering with regard to Forster's moral character. He appears to have been master of seventeen languages; and he was as extensively acquainted with things as with words, being as much indebted for his various knowledge to his industrious and accurate observation of nature, as to his great reading and his profound learning. He was long intimate with Buffon, and was in constant correspondence with Linnæus and his son, the latter of whom gave the name of *Forstera* to a new genus of plants. In conversation he was witty, but too satirical; and his unguarded sallies created him many enemies. He became a fellow of the Society of Antiquaries soon after his arrival in England; in Feb. 1772 was elected a fellow of the Royal Society; and in 1775 he received the honorary diploma of LL.D. from the university of Oxford.

His principal publications are as follows:—*Specimen Historiæ Naturalis Volgensis, Phil. Trans.* 1767, p. 312, containing a description of the country about Saratov. *An Introduction to Mineralogy*, 8vo, Lond. 1768; with a *Translation of* Lehmann's *Halotechnia. A Catalogue of British Insects*, 8vo, Warrington, 1770. *A Translation of* Kalm's *Travels into North America*, 3 vols. 8vo, Warrington and Lond., 1770, 1771. Osbeck's *Voyage to China and the East Indies, translated from the German; with a Faunula and Flora Sinensis*, 2 vols. 8vo, Lond. 1771. *A Translation of* Bossu's *Travels in Louisiana, with Notes, and a Systematic Catalogue of all the known Plants of English North America; together with an Abstract of* Löfling's *Travels*, 2 vols. 8vo, Lond. 1771. *Novæ Species Insectorum*, Centuria 1, 8vo, Lond. 1771; consisting chiefly of English insects. *An Account*

Forster.

of the management of Carp in Polish Prussia, Phil. Trans. 1771, p. 310. *An Easy Method of Assaying and Classing Mineral Substances, with a Translation of* Scheele's *Experiments on Sparry Fluor*, 8vo, Lond. 1772. *Translation of* Bougainville's *Voyage*, 4to, Lond. 1772. *Epistolæ ad* J. D. Michaelis, 4to, Gottin. 1772, containing remarks on this author's *Spicilegium Geographiæ Exteræ. An Account of the Roots used by the Indians in the neighbourhood of Hudson's Bay to dye Porcupines' Quills, Phil. Trans.* 1772, p. 54; the Galium tinctorium and Helleborus trifolius. *An Account of Several Quadrupeds from Hudson's Bay, Phil. Trans.* 1772, p. 370. *An Account of the Birds sent from Hudson's Bay*, p. 382. *An Account of some Curious Fishes sent from Hudson's Bay, Phil. Trans.* 1773, p. 149. Translation of Grainger's *Travels* and Riedesel's *Travels. Catalogue of the Animals and Plants represented in Catesby's Carolina, with the Linnæan names. Characteres generum plantarum, quas in itinere ad insulas maris australis collegerunt* J. R. et G. Forster, fol. Lond. 1776, containing descriptions and figures of 75 new genera. *Liber singularis, de Bysso antiquorum, quo ex Ægyptiaca lingua res vestiaria antiquorum*, 8vo, Lond. 1776. The object of this essay is to prove that the *byssus* of the ancients was cotton, not linen. *Observations made during a Voyage Round the World, on Physical Geography, Natural History, and Ethic Philosophy*, 4to, Lond. 1778. A French translation of this interesting work was added as a fifth volume to that of Cook's Voyage, 4to, Paris, 1778. *Description of the Yerbua Capensis, Swed. Trans.* 1778, p. 108. *Translation of* Von Troil's *Letters on Iceland*, 8vo, Lond. 1780. *On* Buffon's *Epochs of Nature, Göttin. Mag.* 1780, i. i. p. 140. *On the Tiger-Cat of the Cape, Phil. Trans.* 1781, p. 1; the Felis Capensis, found from Congo to the Cape, and capable of being tamed like a cat. *Historia Aptenodytæ, Commentat. Göttin.* vol. iii., p. 121. *Zoologia Indica Selecta*, Latin and German, fol. Halle, 1781, 4to, Lond. 1790; 2d edit. Halle, 1795. *Account of a New Insect, Naturforscher*, vol. xvii. p. 206, Halle, 1782; a species of cancer. *A Picture of England for* 1780, *continued to* 1783, 8vo, 1784; German, 8vo, Dessau, 1784; giving some particulars of many of the principal public characters at the time of the American war. *Essays on Moral and Physical Geography*, 3 vols. 8vo, Leips. 1781, 1783; continued by his son-in-law Matthias Sprengel. *A Collection of Memoirs relating to Domestic Economy and Technology*, 8vo, Halle, 1784. *On the Albatross, Mém. Sav. Etr.* vol. x. p. 563; the Diomedea. *History of Discoveries and Voyages in the North*, 8vo, Francfort on the Oder, 1784; English, Lond. 1786, Fr. Paris, 1788. *Project for abolishing Mendicity, especially at Halle*, 8vo, Halle, 1786. *Enchiridion Historiæ Naturali inserviens*, 8vo, Halle, 1788. *A Memoir on the Badjer Cit. Mém. Acad. Berl.* 1788, 1789, p. 90; the Manis pentadactylus. *Magazine of Modern Voyages and Travels, translated from various Languages, with Remarks*, 16 vols. 8vo, Halle, 1790, 1798. An edition of *Bergius über die Leckereyen*, a work on diet, with notes by Forster, Kurt, and Sprengel, 2 vols. 8vo, Halle, 1792. *A Letter to Schreber on the Persea, Magazin für die Botanik*, vol. v. p. 234. *Onomatologia nova systematis oryctognosiæ vocabulis Latinis expressa*, fol. Halle, 1795, 1 page. *Observations and Truths united to Probabilities, or Materials for a new Essay on the Theory of the Earth*, 8vo, Leipz. 1798.

(Sprengel's *Memoir*; Eyries in *Biographie Universelle*, vol. xv. 8vo, Paris, 1816; Aikin's *General Biography*, vol. iv. 4to, Lond. 1803; Chalmers's *Biographical Dictionary*, vol. xiii. 8vo, Lond. 1814.) (T.Y.)

FORSTER, JOHN GEORGE ADAM, commonly called GEORGE, a distinguished naturalist and circumnavigator, the son of John Reinhold Forster, was born at Danzig in 1754, and enjoyed, in his earliest youth, the advantage of his father's assiduous and affectionate instructions, by which he profited so rapidly, that he was capable, at the age of ten years, when he went with his father into Russia, of ascertaining the species of a plant by comparing it with the Linnæan description. He was for a short time at a school in Petersburg. Upon his arrival in London, he was at first placed in a merchant's counting-house, but soon found his health unequal to the employment, and followed his father to Warrington, where he continued his studies at the academy with so much application, that he became a perfect master of the English language, and otherwise distinguished himself by the strength of his memory and the vigour of his imagination, at the same time that he assisted his father in giving lessons in French, and in completing a variety of translations of voyages and travels. He also accompanied his father, together with Sparrman, in the arduous engagement of making all kinds of physical observations in the circumnavigation of the globe; and he was particularly employed in delineating the various objects of natural history which were discovered. After his return he was elected a fellow of the Royal Society; but he soon quitted England to settle at Paris. In 1779, however, he was appointed professor of natural history at Cassel; and in 1784 he was nominated to a similar situation in the university of Wilna, where he took a degree of doctor of physic; but he found little satisfaction in residing amongst a people so imperfectly civilized. The Empress of Russia had engaged him to take an important part in a new voyage of discovery which she meditated; but the design was abandoned upon the commencement of the war with the Turks. He was next invited by the Elector of Mentz to accept the appointment of president of the university newly established in that city, and he was residing there at the time when the French army entered it. Being a declared republican in his political principles, he was despatched as an envoy to Paris to solicit the incorporation of Mentz with the French republic; but during his absence the Prussian troops retook the city, and he lost the whole of his property, including his numerous manuscripts. He had married a Miss Theresa Hayne, and had one daughter as early as 1788; but, at a subsequent period, his wife's conduct gave him great reason for uneasiness; and though he affected to despise what he called the prejudices of social life, and to excuse her infidelity, and even attempted to facilitate her union with a more favoured admirer, still the affair in reality affected him deeply, and he resolved once more to leave Europe, as if in search of the waters of oblivion; and he was actually preparing for a voyage to Thibet, when his health was subdued by the ravages of a scorbutic disorder, and he died on the 13th February 1792. Besides the assistance which he rendered his father in many of his literary undertakings, he was also the author of a variety of separate publications under his own name.

Forster.

1. *A Voyage Round the World in his Britannic Majesty's Ship Resolution, commanded by* Captain James Cook, *during the years* 1772, 1773, 1774, and 1775, 2 vols. 4to, London, 1777; in German, 2 vols. 4to, Berlin, 1779, 1780, and 3 vols. 8vo, 1784. The style of this work is rather more animated and poetical than that of the official account of the voyage; the second volume is considered as the best written, and the freest from affectation and false sentiment. 2. Mr Wales, the astronomer of the expedition, published some remarks on the work, which occasioned a *Reply to* Mr Wales's *Remarks*, 8vo, London, 1778, in which the author declares that his father had no concern whatever in the book, but he admits that he had committed some inaccuracies. 3. *A Letter to the Earl of Sandwich*, 4to, London, 1779. 4. His *Answer to the Authors of the Literary Journal of Göttingen* exhibits considerable warmth of language, but candidly admits some errors; it excited some further animadversions from Professor Meiners, who declared himself the author of the criticisms. 5. In 1787 he published at Berlin, in 4to, *A Translation of Captain Cook's Third Voyage, performed in* 1776–1780, with an introduction and other additions. 6. *A Description of the Gentiana saxosa, Swedish Trans.* 1777, p. 183. 7. *Life of Dr Dodd*, 8vo, Berlin, 1779. 8. *Preface to Sparrman's Travels*, 8vo, Berlin, 1784. 9. He undertook, together with Professor Lichtenberg, the publication of the *Göttingen Magazine*, which was continued from 1780 to 1785, and published in it, amongst other essays, *A Description of the Red Creeper, or Certhia coccinea of Owhyhee*, i. vi., p. 346. 10. *Experiments with Vital Air*, vol. iii., ii., p. 281; examining its effects on glow-worms. 11. *A Decade of New Plants*, N. Act. Upsal, vol. iii., 1780, p. 171. 12. *On Pygmies*, Hessiche Beyträge, vol. i., p. 1, 1785. 13. *History and Description of the Bread-Fruit Tree*, p. 208, 384; also separately, 4to, Cassel, 1784. 14. *Florulæ Insularum Australium Prodromus*, 8vo, Göttingen, 1786. 15. *Vasculus Plantarum Magellanicarum*, Commentat. Soc. Gött., vol. ix., p. 13. 16. *Plantæ Atlanticæ*, p. 46. 17. *Miscellanies, or Essays on Moral and Physical Geography, Natural History, and Moral Philosophy*, 6 vols. 8vo, Leipsic and Berlin, 1789–1797; the last two volumes are posthumous, and chiefly of a political nature. 18. *Picture of the Lower Rhine, Brabant, Flanders, Holland, England, and France*, taken in the year 1790, 3 vols. 8vo, Berlin, 1791–1794; Dutch, Haarlem, 1792, 1793; French, called *Voyage Philosophique*, 2 vols. 8vo, Paris, 1795, 1796. This work contains many interesting remarks on manners and on the arts, showing that the author possessed very extensive information, as well as originality of talent; but there is too much affectation of sentiment, and an injudicious display of hostility to Great Britain. 19. *Historical Remembrances*

of the Year 1790, 8vo, Berlin, 1793. There are also several political pamphlets of a temporary nature, which could add little or nothing to their author's fame; and a few scattered memoirs in different periodical publications. He was also concerned in the *Collection of Voyages* published by Professor Sprengel; and, together with Pallas and others, in an edition of Martini's *Dictionary of Natural History*. Indeed, his life, though short, was one continued scene of literary activity; but his application to the labour of compilation was too unremitting to allow him to concentrate the whole force of his mind on the performance of any one great original work of genius. The *Sketches of the Mythology and Customs of the Hindoos* were written by another author of the same name.

(*Life* by Pougens; J. R. Forster in *Jacobi's Annals*, and in the *Dedication of his Enchiridion;* Eyries in *Biographie Universelle*, vol. xv., 8vo, Paris, 1816; Aikin's *General Biography*, vol. iv., 4to, London, 1808; Chalmers's *Biographical Dictionary*, vol. xiii., 8vo, London, 1814.) (T. Y.)

FORT, a small fortified place, environed with a ditch, rampart, and parapet. The use of forts is to secure some high ground, or the passage of a river, to make good an advantageous post; to defend the lines and quarters of a siege, and the like. Forts are built of different figures and dimensions, according to the exigencies of the case. Some are provided with bastions, others with demi-bastions; some are of a square form, others pentagonal, and others again are stellated, having five or seven angles. See FORTIFICATION.

Vitrified FORTS. This name has been given to certain remarkable ruins, situated for the most part on the tops of certain hills in the Highlands and northern parts of Scotland. They were first described, about the year 1773, by Mr Williams, an intelligent mineral surveyor. These singular structures derive their appellation of vitrified from the circumstance of the stones composing them presenting the appearance of having been melted or fused by means of fire; thus forming a solid mass of a glassy structure, somewhat resembling volcanic lava, or the refuse of a furnace. In form, size, and situation, they present every variety. Some of them are round or elliptical, whilst others are in the form of squares or parallelograms. In magnitude they vary from a few yards to some eighty or ninety in length, whilst their breadth differs in a proportional degree. The walls likewise vary much in thickness. Some of them are only two or three, and others are about twenty feet in breadth. In height they also differ considerably, having apparently in some instances been twelve feet, and in others not a third of that height. In one or two instances there are a series of walls, two or three in number, inclosing the same area of ground, with a space between each of the works sufficiently large to admit of active defensive operations on the part of those who occupied the place. Their vitrification is very irregular. Occasionally it does not extend a few feet above the ground on which the fabric stands, nor penetrate beyond the surface, whilst in a few instances it rises to the height of ten or twelve feet, and passes inwards to a considerable extent on both sides; and sometimes only isolated parts of the walls show traces of vitrification. They generally occupy commanding positions; but are also found on the sea-shore, and sometimes many miles inland. In general their structure displays nothing like regular masonry. A few of them are approached by regular causeways; and many are furnished with wells, an indispensable requisite for a garrison.

After the publication of Mr Williams's account, the ingenuity of the learned was turned to their probable origin, and many ingenious theories were hazarded on the subject. Some declared them to be of volcanic origin, whilst others contended that they were works of art. The most probable conjecture respecting the vitrification of these structures appears to be, that the ancient inhabitants of Britain, who were unacquainted with the use of mortar, discovered, probably by accident, that some rocks which resist the action of fire become fusible when subjected to a high temperature in contact with certain others; and that the knowledge of this fact led them to employ masses of such mixed rocks in their structures, the stones of which were then cemented together or *vitrified*, by heaping combustibles about them and setting them on fire.

Vitrified remains are of very frequent occurrence in Scotland, more particularly in the northern and north-western counties. Many of these have been minutely described in various works, to some of which we shall presently refer, and in this place shall merely give an account of one or two of the more remarkable of such remains, in order to illustrate their general character.

Dun MacSniochain, which lies in Argyleshire, is thus described by Dr Macculloch.[1] "It is situated on a small rocky hill, which forms a kind of island in the plain, of a narrow prolonged shape, and scarped all round, except at one extremity, which affords access to the summit and the fort. The height of this hill or rock above the plain seems to be about forty or fifty feet; and it is, even in the modern military sense, a strong position. It is important to remark, that the rock consists of limestone and slate intermixed, the plain itself being chiefly alluvial, and the nearest hill and rocks being of trap, and of that pudding-stone so well known to all travellers, which also abounds in the vicinity of Oban. That stone is itself formed of fragments of various trap rocks, and is remarkable for its ready fusibility, while the rock on which the fort stands is of an infusible nature. The fort itself is so contrived as to occupy nearly the whole summit, which is about 250 yards long, and consists of three distinct parallelogramic enclosures. The dimensions of these are as follows, as nearly as could be measured by pacing. The outer is about thirty yards long and about twenty-four broad; the next is about thirty-seven, with a similar breadth; and that at the further extremity is about fifty-six yards in length, but being imperfect, it may formerly have been longer. Besides this, between the first and second works there is a transverse wall which reaches from the one precipitous face to the other, so as, when entire, to have cut off the communication from without to the two inner works. The circumferences of the two inner enclosures make collectively a line of about 260 yards, which, according to the modern military computation for a redoubt, would contain more than 500 men. The external work would dispose of about a hundred more. Hence it is plain that this must have been a military work of some consequence, as capable of holding a large garrison." He continues, "when it is said that the walls here or elsewhere are vitrified, it must not be supposed that they form a solid mass of glass or slag. That condition is very various in different specimens throughout Scotland, and if it is here more perfect than in many, it is less so than in some others. To speak more accurately, many of the stones which form the walls are more or less perfectly slagged or scorified; so that while some have been thus changed throughout, the surfaces only of others are affected, while others again, consisting of less fusible materials, are only burnt. A certain proportion has escaped the fire altogether, or has never been exposed to it; and if we may judge from the ruins, this has taken place chiefly towards the upper part of the wall. The general result, however, is, that in some parts the wall forms a solid mass, but of an irregular composition, consisting of scoria, slag, burnt stones, and stones scarcely altered, united together, but with vacant intervals; while in other places it is separable into lumps of various sizes, and into single stones."

That of Dunadeer is described as follows:—

"The hill of Dunadeer, having an elevation of about 600 feet[2] from the irregular plain on which it stands, with

[1] Macculloch's *Highlands and Western Isles*, vol. i., p. 283.

[2] This is an exaggeration; it is only about 400 feet high at the most.

a steep acclivity all round, has a flat oval summit, which is entirely occupied by the enclosure, so as to form a strong military position. Though much ruined, and consequently obscured, having apparently been used as a quarry for building a more modern castle in the same spot, it is not difficult to trace either the dimensions or the disposition of the original work. The form is a parallelogram, of which one extremity is curved, so as to be nearly semicircular, and its longest side is about fifty-eight yards, the shortest being about twenty-four. The thickness of the wall seems originally to have been eighteen or twenty feet; although, from the state and nature of the ruin, it is impossible to be very accurate in this particular. The highest remaining portion is about six feet above the present surface; and if one foot be added for the increase of soil, and two for the loss which it has sustained at the summit, to be computed from the ruined part at its foot on each side, we shall have eight feet as the probable original altitude.

"The materials of the hill are chiefly gray granite, an infusible rock; but there are scattered in the surrounding plain blocks of a black variety, which, from containing hornblende, is very fusible. To pass over the obviously more modern ruins at this place,[1] as not concerning the present question, there are at a certain stage down the hill the well-marked traces of a work which once seems to have encircled the whole. It is a kind of fortification well known to antiquaries as occurring frequently in the ancient British hill forts; and it resembles a modern military field work, as it consists of a single ditch and wall, the latter being formed of loose stones not vitrified. I consider this as part of the original defences, because a similar one is found on Noath.

"The materials in the vitrified wall are, as at Dun MacSniochain, partly roasted without adhesion, and partly vitrified, or glazed or scorified, in a similar manner. It is easy to see that the dark granite forms the vitrified and scorified substances; but, not to enter on the more minute details, which rather concern the chemist and mineralogist than the antiquary, but which are very interesting to them, I shall only further remark, that wherever stones not capable of vitrification themselves have undergone this change, it has been produced by the alkali of the wood used in the process; whence the glazed surfaces of many unvitrifiable substances.

"Now I remarked that at Dun MacSniochain the materials of the hill itself were not vitrifiable, but that a very fusible rock was present at a short distance, or scattered in fragments about the plain. The same is true here; and in both cases the forts are not erected out of the materials nearest at hand, which are infusible, but collected with considerable labour from a distance. It is hence evident that the builders of those works were aware of the qualities of these various rocks, and it is equally evident that they chose the fusible in preference to the infusible, although with a considerable increase of labour."

Among other vitrified forts more particularly deserving of notice, may be mentioned that upon the hill of Noath in Aberdeenshire; and the large one on the hill of Knockfarril, two miles west of Dingwall in Ross-shire.

Another of these forts is situated about a mile from Inverness, upon the hill of Craig-Phadrick (or Rock of Peter) at the eastern end of the Great Glen, and forming the termination of the high sandstone and conglomerate hills of Loch Ness. Craig-Phadrick is about 435 feet in height above the sea. The summit presents two vitrified walls quite round the area. The space within the inner wall is 80 yards long and 30 broad. It is now overgrown with wood and moss; but in 1812, when the late Mr Telford was engaged in the construction of the Highland roads and bridges, the interior was cleared out, and the vitrification minutely examined. Both the outer and inner ramparts are chiefly composed of a reddish coloured schistus, which seems to have been taken from the south-west end of the fort, where there is an opening that had apparently been occupied by this species of rock up to the common surface. The pieces of stone composing the walls are none of them large. They have been laid down without any order or regularity, and so carried up in this manner to within about two feet of the present top, where a stratum or crowning of small fragments of pudding-stone or conglomerate has been laid on, and by some means brought into a state of vitrification. The great mass of schistus composing the ramparts is quite loose and not vitrified, but nearly the whole of it bears evident marks of having been exposed to a considerable degree of heat, as appears from its yellowish red or brick colour. In the north-west ramparts, especially the outer one, the vitrification is wanting for a considerable space, but the remaining schistus bears all the marks of that found under the vitrification. The most practical-looking conjecture is that over the wall of schistus work was placed a thick layer of timber, faggots of furze or heath, and then a stratum of conglomerate stones laid over all, when the timber, &c., being set on fire would produce the desired vitrification, and give to the lower work the scorched appearance it possesses. Seaware, of which there is abundance at hand, may have been used as a flux. The principal entrance into the fort appears to have been at the north-east end, which was defended by the strongest ramparts, and by a deep trench. The passage over the trench is by a solid dyke composed of similar materials to the ramparts. The entrance at the south-west end is not so well defined, the top of the inner rampart there being nearly as high as the adjacent parts. The chasm or passage through the rock below the outer rampart to the deep hollow which separates Craig-Phadrick from the chain of mountains on the south-west appears to be natural, not artificial, as was conjectured by the late Mr Tytler of Woodhouselee. Such appearances are not uncommon. The four stones or boulders lying on the rocky platform near the brink of this passage are certainly fragments of a larger rock that must once have occupied the platform, and were not placed there, as Mr Tytler supposed, to stop the progress of an invading army. The largest of the boulders is about 10 or 11 tons weight, and a whole regiment might have passed before it could have been put in motion by manual labour, while the other stones are too small to have given any serious obstruction to an enemy. It has been stated that there is a well of about 6 feet in diameter at the summit of Craig-Phadrick, in the centre of the inner area, but this is a mistake. There is no water nearer than a spring about 300 feet perpendicular below the summit of the hill. From the scarcity of water and the want of room, cattle could not have been admitted for any length of time into the fort, and it is probable that at the date of these erections the principal animal food of the people was that procured by the chase and hunting in the forests. The theory that the vitrified forts were merely beacons to warn the country of approaching invasion, seems inadmissible. The circular ramparts and vitrification are too regular to guarantee this supposition. They may, however, have been used in the middle ages as sites for alarm fires; and Craig-Phadrick is within sight of a chain of similarly vitrified structures communicating over the country; but there are others (in Nairnshire for example) which could not have answered for this purpose. They are much more likely to have been the fortified residences of petty chiefs at a period before the use of lime cement was known in the north of Scotland—perhaps ages before the Scandinavians

[1] **This, we presume, refers to the remains of an oblong tower constructed of lime, mortar, stone, and fragments of the earlier vitrified fort, to which the opponents of Dr Macculloch ascribe a more modern date than belongs to the rest of the structure.**

were possessed of knowledge requisite for equipping fleets powerful enough to give much disturbance to their southern neighbours. The baronial castles and forts of the middle ages are frequently found in situations nearly as inconvenient for domestic comforts as the more ancient vitrified forts.

In the parish of Meigle, Perthshire, there is a hill called Barryhill, which appears to have been strongly fortified, though without any attempt at cementing stones; but at the south-east extremity of the fort there was a vitrified mass in the form of a wall or dyke occupying the bottom of the trench between the summit and the outer rampart.

Near Creich, in the county of Sutherland, there are some vitrified remains; as also near the church of Amwoth, in the county of Kirkcudbright; and in the island of Bute, in the parish of Kingarth, there is a vitrified fort. In Cantyre, at the entrance of the bay of Carradale, on a small island, about a rood of ground is enclosed by vitrified masses, Others have been observed in Argyleshire, particularly one on the hill of Dunskeig, which commands the entrance of Loch Tarbert.

On the hill of Laws, near the village of Sturdymuir, a few miles north-east from Dundee, there is a vitrified fort. About four miles east from Forfar is the castle-hill of Finhaven, the vitrifications on which have been compared by Dr Anderson to the effects of fire in a limekiln.

It is impossible in this place to point out all the vitrified ruins, amounting to about fifty, and extending over Perthshire, Forfarshire, Kincardineshire, Aberdeenshire, Banffshire, Morayshire, Inverness-shire, which contains an immense number, Ross-shire, Cromartyshire, Argyleshire, Buteshire, Berwickshire, and Galloway. Dr Hibbert, in a paper read to the Society of Antiquaries of Scotland in 1831, informs us that he had discovered masses of vitrified matter at Elsness in Sanday, one of the Orkney islands. Of these curious remains, which he calls vitrified cairns, or beacon cairns, he counted more than twenty. They are of a round shape, from three to five yards in diameter, and elevated from two to three feet above the surface of the ground. The stony fragments of which they are composed appear to have been collected from the beach, and consist of an argillaceous schist. Their fusibility they derive chiefly from the feldspar, or rather the alkali, which they contain. For further information respecting vitrified forts and similar remains of antiquity, see Macculloch's *Highlands and Western Isles; Archæologia Scotica; Transactions of the Society of Antiquaries of Scotland*, vol. iv., &c. &c.

FORT-AUGUSTUS, FORT-GEORGE, and FORT-WILLIAM. See Inverness-shire.

FORT ST DAVID, a town of Hindostan, on the sea-coast of the Carnatic, situated on the river Tripapolore. Three rivers of considerable size all fall into the sea in the space of four miles within the bounds of Fort St David. The Panaur is about 1800 yards to the north of the Tripapolore, and the two streams communicate by a canal which runs parallel to the margin of the sea, from which it is distant about 1000 yards. Fort St David stands in the angle formed by the junction of the canal with the Tripapolore, which passes close to the site of the fort, and then sends to the south an arm that joins at no great distance the river of Bandapollam, where both in one channel continue along the eastern side of Cuddalore, separated from the sea by a mound of sand. This factory was first established in the year 1691. After the capture of Madras by the French in 1746, the English were besieged here without success; and from this period it continued the head of the English settlements till 1758, when it was taken by Lally after a short siege, and the fortifications were destroyed. It is 100 miles S.S.W. from Madras, and 15 S.S.W. from Pondicherry. Long 79. 50. E., Lat. 11. 46. N.

FORTALICE, the name given in Scotland in former times to a small place of strength, built for the defence of the country, and which on that account was considered as belonging to the king, and consequently did not go along with the lands upon which it was situated without a special grant from the crown. Now, fortalices go as part and pertinent of the lands.

FORTAVENTURA, or Fuerteventura, one of the Canary Islands. See Canary Islands, vol. vi., 167.

FORTESCUE, Sir John, an eminent English lawyer in the reign of Henry VI., was descended from an ancient family in Devonshire, though both the time and place of his birth are unknown. He is supposed to have been educated at Oxford, and the great learning displayed in his writings does no discredit to such a supposition; but it is nevertheless altogether uncertain at which university he studied, or whether he ever studied at any. When he turned his views to the legal profession he entered himself of Lincoln's Inn, where he soon distinguished himself by his knowledge of the civil as well as of the common law. In the fourth year of Henry VI. he was appointed one of the governors of Lincoln's Inn, and three years afterwards the same office was again conferred upon him. In 1441 he was made a king's serjeant at law, and the following year chief justice of the King's Bench. As a judge Fortescue is highly commended for his wisdom, gravity, and uprightness; and he seems to have enjoyed great favour with the king, who is said to have given him some substantial proofs of esteem and regard. He held his office during the remainder of the reign of Henry VI., to whom he steadily adhered; and having faithfully served that unfortunate monarch in all his troubles, he was attainted of treason in the first parliament of Edward IV., which assembled at Westminster in November 1461; having been included in the same act by which Henry VI., Margaret of Anjou his queen, Edward their son, and many persons of the first distinction, were likewise attainted. When Henry subsequently fled into Scotland, he is supposed to have appointed Fortescue, who appears to have accompanied him in his flight, chancellor of England; and although the name of the latter is not found recorded in the patent rolls, because, as Selden remarks, "being with Henry VI. driven into Scotland by the fortune of the wars with the house of York, he was made chancellor of England while he was there," yet several writers have mentioned him by this style and title; and in his book *De Laudibus Legum Angliæ*, he calls himself *Cancellarius Angliæ*, which seems to settle the question. Early in 1463, Fortescue embarked at Bamberg with Queen Margaret, Prince Edward her son, and many other persons of distinction who followed the fortunes of the house of Lancaster, and landed at Helvoetsluys, from which the party were conducted by Bruges and Lisle to Lorraine. Being thus expatriated, he remained many years on the Continent, moving about from place to place, as the necessities of the royal exiles required, and endeavouring to promote their interest by every means in his power. But his most important labours during this period were of a different and more lasting kind. Having observed that Prince Edward applied himself wholly to military exercises, and seemed to think of nothing but qualifying himself to command in battle, Fortescue, who had observed in him indications of a sound understanding, judged it high time to endeavour to give him other impressions, and particularly to infuse into his mind just notions of the constitution of his country, as well as a due regard for its laws. With this view he drew up his celebrated work *De Laudibus Legum Angliæ*, which, though it failed of its primary intention, owing to the barbarous murder of the young prince for whose benefit it was composed, will yet remain a lasting monument of the author's learning and patriotism. When the prospects of the exiles began to brighten a little, the queen and the prince returned to England, accompanied by Fortescue and others, who no doubt hoped that a more

Forth.

auspicious day was about to dawn upon the descendant of time-honoured Lancaster. But destiny still counter-worked the designs of the heroic Margaret. Her attempt to assert the rights of her son totally failed; and the chancellor, forced to reconcile himself as he best could to the victorious Edward IV., wrote an apology for his conduct, which, though Selden had seen it, has never been published. Little further is known respecting the life of this remarkable man, excepting that, amidst all the changes of masters and varieties of fortune, he steadfastly maintained those constitutional principles which he had with equal ability and conciseness explained in the celebrated treatise above referred to. He appears to have died at a very advanced age, though the time of his death, like the date of his birth, has not been ascertained.

Fortescue's masterly vindication of the laws of England, though received with great favour by the learned of the profession to whom it was communicated, did not appear in print until the reign of Henry VIII., when it was published by Whitechurch in 16mo, but without a date. In 1516 it was translated by Mulcaster, and printed by Tottel; and again in 1567, 1573, and 1575, and also by White in 1598, 1599, and 1609. It was likewise printed, with Hengham's *Summa Magna et Parva*, in 1616 and 1660, 12mo; and again with Selden's notes in 1672, in 12mo. In 1737 it appeared in folio; and, in 1775, an English translation, with the original Latin, and Selden's notes, besides a variety of remarks relative to the history, antiquities, and laws of England, was published in 8vo. Waterhouse's *Fortescue Illustratus*, which appeared in 1663, hough prolix and defective in style, may be consulted with advantage, and will serve to facilitate the labours of more judicious and able inquirers. 2. Another valuable and learned work by the same author, but written in English, was published in the reign of Queen Anne, under the title of The Difference between an absolute and limited Monarchy, as it more particularly regards the English Constitution, and accompanied with some remarks by John Fortescue Aland of the Inner Temple, London, 1714, in 8vo; and a second edition with amendments appeared in 1719, 8vo. In the Cotton Library there is a manuscript of this work, in the title of which it is said to have been addressed to Henry VI.: but many passages show plainly that it was written in favour of Edward IV. 3. Of the author's other writings, which were pretty numerous, but never printed, we know nothing more than can be collected from the titles, and the commendations bestowed on them by persons who had perused the manuscripts. Those still extant are, 1. *Opusculum de Natura Legis Naturæ, et de ejus censura in successione Regnorum Supremorum;* 2. *Defensio juris Domus Lancastriæ:* 3. Genealogy of the House of Lancaster; 4. Of the Title of the House of York; 5. *Genealogiæ Regum Scotiæ;* 6. A Dialogue between Understanding and Faith; 7. A Prayer Book which savours much of the Times we live in; with some others, which, as the author was a man of great knowledge and observation, will, we trust, yet be printed. When lord-chancellor, Fortescue is said to have drawn up the statute of the 28th Henry VI. on the resumption of certain grants of the crown, which, though much relied on by writers on that subject, is not extant in any edition of the statutes. (J. B—E.)

Length, breadth, and depth.

FORTH, one of the largest rivers in Scotland. It is first formed of several small streams rising on the north of Ben Lomond, or flowing from Loch Katrine and the other lakes in the adjacent country. It proceeds easterly in a direct course for above 100 miles, receiving in its progress the tributary waters of the Goodie, the Teith, and the Allan above Stirling, and below it the Devon, the Carron, the Avon, the Almond, the Leith, the Esk, the Leven, the Tyne, and others; and it discharges itself into the German Ocean in about 56. 10. of north latitude. The windings of the Forth, both above and below Stirling, are extremely beautiful. From its junction with the Teith above Stirling to the carse ground below Gartmore the windings extend about 28 miles, although the distance in a direct line is only about 20. From Stirling harbour to Alloa the length of the river is $10\frac{1}{2}$ miles, although in a straight line it is not more than 5, and here it is comparatively narrow, shallow, and winding. From Alloa to Grangemouth the distance is 5 miles; and here the Forth widens, with a variable depth of from 4 to 15 feet at low water. From Grangemouth to the Long Craig Beacon at North Queensferry, a distance of 10 nautical miles, proceeding downwards the depth increases in the first mile from 10 to 15 feet, and in the second mile to 25 feet at low water, and at the third mile to 53 feet, while the remaining part of the distance—7 miles, including the great anchorage of St Margaret's Hope—has a depth generally of about 60 feet at low water. At Queensferry the river is 2 miles wide; at Kinghorn nearly 6; between Dysart and Aberlady about 12; and between St Abb's Head and Fifeness, where the Forth joins the German Ocean, it is from 35 to 40 miles. Near Queensferry, between Inchgarvey and the north shore, it deepens to 37 fathoms. Between Elie and the south shore its depth is sometimes 30 fathoms; and it never exceeds this depth to the westward of its junction with the north sea, except as above stated.

Tides.

The Forth, like other streams connected with the ocean, ebbs and flows twice in 24 hours, but the flood and ebb run about two hours longer in the middle than at the shore. The tide flows $4\frac{1}{2}$ miles above Stirling shore. At this harbour spring tides rise 7 feet 9 inches, and at Alloa $19\frac{1}{2}$ feet.

It was high water, according to Captain Thomas's observations in 1815, at

	H. M.	Spring Tides rise	Neap Tides rise
Elie Harbour	2.11 p.m.	14 feet.	6 feet.
Leith and Burntisland	2.15 „	$16\frac{1}{2}$ „	7 „
Hopetoun House	2.30 „	17 „	$6\frac{1}{2}$ „

The tides at Leith and Kinghorn rise sometimes as high as 19 feet above low-water mark, the average being $17\frac{1}{2}$ feet.

Currents.

There are in the Forth, as elsewhere in similar rivers and arms of the sea, particular currents. Among the most remarkable are those known by the name of *Leakies* above the Queensferry, which are particularly observed from Culross to Alloa. "These consist in an intermission of the tide at certain places during the flood, and before high water the sea ebbs. On the contrary, while the sea ebbs, and before low water, the ebb intermits, and a flow commencing, continues some time; after which the ebbing is resumed until low water. This is seen during two hours, and the irregularity occupies more or less of the river according as it is spring or neap tide."

Winds.

Certain winds, acting upon the great mass of the Atlantic Ocean, affect the times at which it is high or low water in the Forth, while their effect upon the extent of the rise or fall of its waters is frequently very considerable.

The prevailing winds of the Forth will be seen by the following table, constructed from observations taken every day, at ten o'clock forenoon, on the island of Inchkeith, for the ten successive years ending on 31st December 1826.

Direction of the Winds.	Description of the Winds.				
	Light Airs.	Breezes.	Gales.	Storms.	Total.
South	96	165	29	2	292
South-West	42	181	111	5	339
West	275	807	267	22	1371
North-West	44	157	13	3	217
North	26	105	20	1	152
North-East	68	90	23	24	205
East	334	345	34	26	739
South-East	104	109	6	5	224
Changeable	101	12	...	...	113
	1090	1971	503	88	3652

The prevailing winds and their relative force, as indicated at the Calton Hill Observatory, may also be seen from the following table constructed from the observations taken there every day under the superintendence of the astronomical observer for the same ten years, ending on 31st December 1826. The entry in the register for each day is applicable to the winds of its whole 24 hours.

Direction of the Winds.	Description of the Winds.						
	Moderate and Calm.	Brisk.	Sharp.	High.	Very High.	Extremely High.	Total.
South	85	2	...	17	3	4	111
South-West.....	310	43	1	178	68	30	630
West..............	444	54	3	235	54	8	798
North-West.....	207	33	4	143	48	9	444
North	61	6	4	17	5	...	93
North-East	122	11	2	21	2	...	158
East..............	381	37	4	45	4	...	471
South-East......	131	8	3	14	2	...	158
Changeable.....	588	44	4	119	29	29	789
	2329	238	25	789	215	56	3652

From these tables it will be observed that the prevailing winds in the Forth, the gales and the storms at Inchkeith, and the "very high" and "extremely high" winds at the Calton Hill Observatory, chiefly proceed from westerly directions.

Waters. The waters of the Forth and its tributary streams are all fresh until they mingle with that of the ocean. Long before the river becomes two miles wide they acquire a saltness which differs little, if at all, from that of the sea. The water in the neighbourhood of the coal-works on the Forth has been often evaporated for the sake of the salt, which was here at one time an extensive article of manufacture.

The constituent parts of 10,000 parts of the waters of the Forth were found by Mr Murray, in the course of three different analyses made in different ways, to contain

Muriate of soda	242·51	245·04	220·01
Sulphate of magnesia...............	7·86	17·04	...
Sulphate of soda......................	9·99	2·66	33·16
Muriate of magnesia	34·49	28·63	42·08
Muriate of lime	...	...	7·84
Sulphate of lime......................	9·45	9·72	...
	304·30	303·09	303·09

Mr Murray placed most confidence in the results obtained from the last of these analyses.

Minerals on the banks. The minerals of which the banks of the Forth are composed will be found described under the counties of East Lothian, Mid-Lothian, West Lothian, Stirling, Clackmannan, Perth, and Fife, by all of which the Forth is bounded. Coal, besides being wrought in these counties, was once worked near Culross and Torryburn under the bed of the river, and partly by pits within high-water mark. At the mouths of these pits there were piers, at which vessels were loaded with coals. But the mines above referred to have for many years been filled with water. At West Wemyss, however, there are still extensive coal mines worked under the sea.

Bed of the river. The bed of the Forth consists to a great extent of mud, and in many places the sandstone bottom is covered with it to the depth of 20 feet. Its banks above Alloa, and a great way below that place, are formed of this material, which is brought down by the waters from the higher levels; and the carses of Stirling and Falkirk, &c., which have been formed from its accumulation, are secured at their lowest levels by sea dykes against inundations occasioned by the rise of the tides. The recent alluvial cover to the westward of Alloa has been found by Mr Bald in some places to be no less than 90 feet deep, and to contain trunks and branches of large trees, and beds of sand and sea shells, particularly of the oyster, cockle, mussel, donax, &c.; and similar beds of shells not only abound at and below Alloa, but are found several miles to the westward of Stirling similarly situated. Many of the oyster-shells are of uncommon thickness, and larger than any specimens that can now be found. What makes the westerly position in which these uncommonly large shells are found very remarkable is that there are no specimens of the oyster now found farther up the Forth than Queensferry.

There is also a bed of marine shells on the banks of the Forth near Borrowstownness about three miles in length and several feet in thickness, and which is situated many feet above the present level of the waters of the Forth. This circumstance would favour the opinion that the sea in this quarter had at one time occupied a higher elevation in relation to the land than at present; an opinion which is farther supported by the fact of the skeleton of a large whale having been found some time ago in the lands of Airthrey, near Stirling. The surface of the ground where the remains of this huge marine animal were deposited was ascertained by Mr Stevenson to be 24 feet 9 inches above the present level of the high water of the Forth at spring tides. The skeleton of another whale, with a bone harpoon sticking in it, was also found seven miles farther inland, on what is now the Blair Drummond moss.

But if the land has been gaining on the waters in the upper part of the Forth, ground has been lost farther down the estuary. The sea has made considerable encroachments at North Berwick; at Newhaven an arsenal and dock, built in the reign of James IV. in the fifteenth century, has been swept away. On the coast of Fife, in 1803, the last remains of the Priory of Crail and the ground on which it stood met with a similar fate; and no traces can now be found of the lands which extended into the sea, and formed, in 1225, the estuary, the fisheries of which were then a subject of an important dispute between the monks of Dryburgh and those of the Isle of May; all that now remains of this estuary is a small streamlet called the Drill burn, which flows through a portion of the sands in West Anstruther harbour.

At Largo Bay the sea seems now to be covering ground which was formerly dry land. Here a submarine forest has been discovered, the roots of the trees penetrating into a brown clay, over which is irregularly distributed a covering of sand and fine gravel. The peat upon it is composed of land and fresh-water plants, amongst which are hazel nuts, and the remains of birch, hazel, and alder trees. The root of one tree, apparently an alder, was here traced by Dr Fleming to an extent of more than 6 feet from the trunk.

Sea-weed. On almost all the shores of the Forth there is an abundant supply of sea-weed, which has often been burned at various places to form kelp, but this trade is now given up. The produce of the rocks and what is cast ashore in storms is now therefore only used as manure.

Large fishes. Numerous porpesses are often seen tumbling and disporting in the firth, and seals lying on the rocks or swimming along the coasts. Sharks of several species have occasionally made their appearance, and have been brought ashore by the fishermen in their nets about Anstruther and elsewhere. Numerous cetacea from 20 to 30 feet long have often been stranded in the Forth. From twenty-five to thirty of these animals were at one time on shore between Cambuskenneth and Alloa. A male Beluga or white whale, apparently of full growth, appeared in its waters in 1815. It was killed by the salmon fishers near the same place, and sent to Edinburgh, where it was dissected by the late Dr Barclay.

Salmon. The salmon is abundant in the Forth, and salmon fisheries have been established for many years at Stirling, Abercorn, near Queensferry, and many other places on both sides of the firth, as far down as Largo Bay. The whole of these fisheries belong to thirty proprietors, and such of them as were let in 1854 produced a gross rental of L.1316. The rent of the town of Stirling's fishing then amounted to L.354, of another proprietor to L.240, of another to L.126, of two others to L.70 each, and others were let under that

Forth.

sum, a few at a rent of L.5, and thirteen of them brought no rent at all, as they appear to have been considered of little value.

Herrings, &c.

Herrings are also plentiful in the Forth, and at various fishing stations the fishery is prosecuted successfully. To give some idea of its extent, in the Anstruther district in Fife, which includes all the sea-ports from St Andrews to Buckhaven inclusive, the total number of barrels or crans of herrings taken (1854) amounted to 17,906½, whereof 11,468 were sold fresh, 3699½ were sold and exported to Continental markets, and 2739 cured and sent to Ireland.

The number of full-sized cod and ling caught and cured was 84,855, of which 1089 cwts. were dried, and 1865½ barrels were pickled. In addition to these, 9958 cwts. of full-sized cod and ling were caught and sold in a green state and sent to and consumed in Leeds, Preston, Birmingham, Edinburgh, Glasgow, Cupar, Stirling, Perth, Dundee, &c. The value of the annual average of haddocks sold fresh has lately been estimated at L.4000, of smoked L.12,000, of turbot, halibut, lobsters, crabs, &c., L.458, and of periwinkles, L.136.

There were engaged in this district, in 1854, 500 boats, 2099 fishermen, 97 coopers, 1444 gutters and packers, and 1063 labourers, all in the employment of 68 fish-curers. The value of the boats and their appurtenances was reported to the fishery commissioners to be L.61,991.

In the Leith district, which includes all the portion of the firth above North Berwick on the south, and East Wemyss on the north shore, the total number of crans or barrels of herrings taken (in 1854) were 16,045½, whereof 6695½ were cured, and 9350 were sold fresh; 13,714½ were sold to Continental markets, and 496½ sold and sent to Ireland. The number of ling and cod caught by the fishermen of this district were all sold fresh, and have been estimated to the commissioners at 5900. All the other fish caught here were also sold and consumed in a fresh state. There were employed in this trade, in 1854, 354 boats, 1166 fishermen, 100 coopers, 489 gutters and packers, and 224 labourers, all in the employment of 25 curers. The value of the boats and their appurtenances was reported to be L.21,771.

Besides the fisheries in the Forth above stated, there were 35 boats, 134 fishermen, 25 coopers, 205 gutters and packers, and 40 labourers employed in the same trade by 2 curers at Canty Bay, and 30 at Dunbar, and the fish taken by them are generally sold fresh.

In addition to the Scotch fishermen, it may be mentioned that all parts of the firth are occasionally fished by English vessels, and a dozen at a time of English fishing smacks, and as many as 20 French boats, have been occasionally seen by the Anstruther fishermen to be so employed; 40 sail of foreign vessels were at one time known to have been fishing cod near St Abbs' Head.

Shell-fish, &c.

Lobsters and crabs are caught at all the fishing-stations in the Forth, as well as in the Anstruther district. Mussels, cockels, limpets, and whelks are also collected and sold in great quantities at the places where they abound, and oysters are extensively fished at the oyster beds, which are met with near Inchkeith and farther up the Forth.

Wild-fowl.

There is nothing remarkable about the wild fowl resorting to the firth in winter. The solan geese of the Bass have been already described under the head BASS, to which the reader is referred.

Islands.

Besides the Bass, in the entrance to the Forth, there is another island, the May; and the larger islands farther up the Forth are Inchkeith, Inchcolm, and Inchgarvey, which will be found described in separate articles. The smaller islands are Fidra, the Lamb, and Craigleith, near the Bass, and Mickry and Cramond islands, near Inchcolm.

Fords, and peat accumulation.

The principal obstructions to the navigation of the Forth between Alloa and Stirling have hitherto arisen in a great measure from the two fords of the river, the one called the Town ford and the other the Abbey ford, and from the channel being rendered shallow partly by large boulders and partly by accumulations of peat. The peat accumulations have arisen chiefly from the proprietors above Stirling clearing several thousand acres of their lands for cultivation, by removing the peat which covers them, and moving it into the river in order to be carried away by the current to the sea. This practice has been followed since 1732. The moss covering the soil varies in depth from 14 to 4 or 5 feet, but the greater proportion is 10 feet. Mr Drummond of Blair-Drummond, from 1783 to 1839, floated away upwards of 1600 acres of this substance.

Sand-banks.

The principal sandbanks which obstruct the navigation farther down the firth are the Drum-sands, near Cramond, and the Sand-end on the east of Burntisland harbour.

Dangerous rocks.

The principal rocks which require to be avoided by the mariner are the South Carr Reef, lying N.N.W. from Dunbar, the North Carr, about a mile and a quarter east of Fifeness, the Blae to the west of Kinghorn Ness, the Commons to the west of Burntisland, Craig Waugh S.E.½E. of Inchkeith, and the Gunnet Rock, Pallas Rock, Long Craig, Briggs, and Harwit in its neighbourhood; and several miles farther west and nearer Inchcolm, the Oxcares, Carcraig, and Mickry Stone. Many of these rocks are seen at the lowest ebbs; their position, together with the different land-marks, which are necessary to point them out to the mariner, are delineated on the Admiralty Charts, and the sailing directions for the Frith of Forth, contained in the *Coaster's Assistant*, which is published in Leith. To show their position still better, floating buoys have been placed upon Craig Waugh, the Gunnet, the Harwit, and the Pallas Rocks; and beacons have been erected on the Oxcares, the North Carr, and on the Long Craig, and on most of the other dangerous rocks, and on several shoals and sand-banks.

Beacons and buoys

Light-houses.

Besides these provisions for aiding the navigation, there are two lighthouses on the Isle of May, one on the Island of Inchkeith, and various other lighthouses are now erected on all the harbours and landing places of importance in the firth.

Anchorages.

The anchorage of the Frith of Forth is excellent. Mr Osborne, in a report to the Lords of the Admiralty on 2d May 1853, says of it, "Between the Humber and the Frith of Cromarty there is no other harbour or anchorage into which large ships of war can safely run for shelter or rendezvous other than the Frith of Forth, and more particularly in the reach above the Queensferry, where the shelter is complete. But as the Frith of Cromarty is away from all important interests, the Frith of Forth must be considered the only war port north of the Humber, and therefore a most fitting place for a naval arsenal." But besides the great and important anchorage at St Margaret's Hope, in the reach above the Queensferry, which is more particularly referred to in this Admiralty Report, Leith Roads to the west of Inchkeith is another which is capable of holding a large fleet of ships of war of any size. The minor anchorages in the firth, which are also very good, are at Aberlady Bay, the western part of Largo Bay, Burntisland, St Davids, Limekilns, &c.

Harbours.

The landing-places in the Forth are, on the south side the harbours of Dunbar, North Berwick, Port Seton, Morrison's Haven, Fisherrow, Leith, Newhaven, Trinity, Granton, South Queensferry, Borrowstownness, Grangemouth, and Stirling shore, and on the north side Crail, Anstruther, Elie, Pittenweem, Leven, Methel, West Wemyss, Dysart, Kirkcaldy, Kinghorn, Pettycur, Burntisland, Starleyburn, Aberdour, St Davids, Inverkeithing, North Queensferry, Charleston, Crombie Point, Culross, Kincardine, and Alloa. Great improvements and new erections have been lately made at most of these harbours which are of any note; and in particular, the Duke of Buccleuch's magnificent harbour in

Forth. progress of formation at Granton, and the extension of Leith Pier into deep water may be referred to. Of less magnitude is the deepening of the channel of the Forth between Alloa and Stirling by commissioners acting under the Act of Parliament 6th and 7th Victoria, cap. 47. Since the passing of this act in 1843, a channel of about 500 yards in length has been formed through the Abbey ford, giving about 3 feet 6 inches greater depth of water than formerly. A channel about 1000 yards in length has also been formed through the Town ford, which is not yet fully completed as regards its depth of water. In these operations many thousands of large boulder stones and the peat accumulations which formed obstructions to the navigation have been removed, and no doubt is entertained by the inspectors, who have reported to Government on the subject, but a depth of 16 or 17 feet at spring-tides will be obtained up to Stirling when the works in progress are completed. Upwards of L.9000 (including the expense of the act and of erecting a quay at Stirling) have already been expended by the Harbour Commissioners on these operations, and L.7000 more is about to be expended upon them. This sum is to be paid to the commissioners by the town-council of Glasgow for damage likely to arise to the improvements in progress on the Forth, from the liberty obtained by the City of Glasgow to draw a large quantity of water from Loch Katerine. In addition to these sums the revenue of the Forth Commissioners, which is considerable, will enable them still further to extend their works.

Further, the low-water ferry landing-place at Burntisland, belonging to the Edinburgh, Perth, and Dundee Railway Company, is a great improvement at that port; and at Kirkcaldy, Buckhaven, and other harbours, extensive works are in progress under Harbour Commissioners.

Coasting and foreign trade. The coasting and foreign trade of the Forth is carried on in vessels varying in size from 18 to 500 tons. The principal port to which they belong is Leith; but there are several whalers and large vessels engaged in the Australian, American, Mediterranean, and Baltic trades, which belong to other ports in the Forth.

The traffic in goods and passengers between the ports in the Forth and London, Greenock, Glasgow, Liverpool, Hull, Newcastle, Dundee, Perth, Aberdeen, Inverness, Peterhead, and almost every considerable seaport in Scotland, is conducted chiefly by vessels of joint-stock companies, which vessels sail periodically. Joint-stock companies are also engaged in the Leith trade with Hamburgh and Rotterdam. The Glasgow, Greenock, and Liverpool trade is chiefly conducted through the Forth and Clyde Canal, as to which see NAVIGATION, *Inland*, and GRANGEMOUTH.

Forth.

The number and tonnage of the vessels belonging to the ports in the Forth in 1855 are as follow:—

At Alloa, including the creeks of Kincardine and Stirling, 74 vessels, with a tonnage of	12,402
At Borrowstownness, including the creeks of Charleston and Limekilns, 47 vessels, with a tonnage of......	3,781
At Grangemouth, 54 vessels, with a tonnage of.........	9,233
At Inverkeithing, 23 vessels, with a tonnage of.........	2,361
At Kirkcaldy, including the creeks of Largo, Leven, Wemyss, Dysart, Kinghorn, Burntisland, and Aberdour, 60 vessels, with a tonnage of	7,687
At Leith, including the creeks of Granton, Fisherrow, Cockenzie, and Dunbar, 176 vessels, with a tonnage of..	25,404
Total 434 vessels, with a total tonnage of	60,868

Bridges and ferries. To facilitate the communication between the northern and southern parts of Scotland by a passage across the Forth, wooden bridges were erected at an early period, and the old stone bridge of Stirling was erected before 1571; the new stone bridge and the railway bridge near it were erected only a few years ago. There was once a project of erecting a suspension bridge at the Queensferry, and another project of making a tunnel there; but both the schemes were abandoned.

The passage of the river and firth by ferries has been an object of legislative enactment since 1467. Before the introduction of steam navigation, the traffic at these ferries was chiefly conducted by open boats, pinnaces, and yawls of various sizes, and from the want of low water piers they seldom departed from either side except at high water. Most of these ferries are still private property. The private rights of the Queensferry passage were purchased by Parliamentary Trustees in 1809, and large sums have been expended on its improvement. The ferries of Kinghorn and Burntisland were also under Parliamentary Trustees for many years; but they have now ceased to be so, and the Fife and Mid-Lothian ferries and their landing-places at Kinghorn, Pettycur, and Burntisland, are now the property of the Edinburgh, Perth, and Dundee Railway Company, who afford the ferry accommodation as a portion of the railway business. For the extent and particulars of this trade, reference is made to the article FIFE.

FORTIFICATION

Is the art of securing a portion of ground, whether occupied by a town, or including within it a dock-yard, port, or harbour, or serving, in military language, as the position of an army, from the attack of an enemy, by surrounding or covering it with works of defence; and as such works are so many obstacles placed in the way of the advance of their assailants, whilst they are at the same time the means of sheltering the defenders, it is the art of enabling a small number of men to defend themselves against the attack of a much larger. Various modifying terms have been adopted in connection with the general one of fortification, but none of them are of much use in considering this subject, and some may lead to error, by inducing an engineer to restrict himself under some circumstances to a very limited view of his subject. Thus, fortification natural and fortification artificial, imply a very useless distinction, as every engineer must avail himself both of the natural advantages or obstacles of the ground, as well as of the obstacles his science and genius enable him to add to them; and thus in every fortification nature and art must act together. Again, fortification regular and fortification irregular, are terms equally defective, as no fortification can be possibly regular unless it should so happen that the ground it occupies, as well as the ground surrounding it, is on all sides perfectly identical in its levels and general character. Fortification permanent and fortification field or temporary, refer again only to the immediate object of the works, or to the application of the science, and in no way affect its principles, which remain the same whether the work is a simple earthen intrenchment, or a great fortress surrounded by masonry walls. Fortification offensive and fortification defensive, are of all the most objectionable terms, since, strange as it may appear, they imply a contradiction to fact, as the perfection of defence depends as much on its active or offensive operations as on the protection its covering works afford, whilst the perfection of attack is equally dependent on the skill with which its covering works are constructed and pushed forward towards the fortress attacked, as on its offensive operations, or on the fire of its batteries.

The principles of defence then should be studied unshackled by any of these limiting distinctions, and the engineer should apply his means to his end, using without restriction the works best suited to his purpose; and it is in this way that the study of the subject will be here treated.

ELEMENTARY FORTIFICATION.

It is often desirable to examine the exact meaning of technical words, as a ready mode of acquiring a distinct notion of the ideas they were intended to convey; and of obtaining a glimpse of the historical progress of the science in which they are used. Fortify, Fortification, Fortress, Fort, are all words depending on the Latin words *fortis*, *forte*, strong, and *fortifico* or *forte facio*, to make strong; hence the idea they suggest is that, by some artificial or other arrangement, additional strength is bestowed upon one combatant over another, or upon one party of combatants over another party. A shield, the trunk of a tree, or bank of earth, or any other similar contrivance which shelters the body of one soldier from the missiles of his opponent whilst it leaves him free to discharge his own, may be considered a simple element of fortification.

A bank of earth, when reduced to the requisite thickness, and moulded into a proper form, with such slopes as the particular tenacity of the earth may require to insure stability, or which the intended direction of the fire over its summit may render necessary, becomes a parapet, so called from the Italian words *para*, a defence or guard, and *petto*, the breast, or, in English, a breastwork. If the breastwork or parapet were only made sufficiently high to permit the soldier to fire over it, he would be greatly exposed after firing, and be forced to crouch down in order to obtain cover. The parapet is therefore made sufficiently high to cover the soldier when standing up, so as to enable him with ease and security to reload, as well as to move from one place to another. This increased height has rendered it necessary to introduce a banquette or step (accessible by an easy slope) from which the soldier can fire and then retire by the interior slope to the lower ground behind it; the name banquette being derived from banchetta, a little bench or step. As parapets are usually formed artificially, the earth for their construction is derived from a ditch, which being dug immediately in front of and parallel to the parapet, forms by its depth an additional obstruction to an advancing enemy. Ordinary intrenchments are formed of the simple parapet and ditch, but in forts and fortresses the height is still further augmented by elevating the parapet on another mound of earth called the rampart (*riparo*, in Italian), and as this additional mass requires a greater quantity of earth, the ditch is also made both wider and deeper. In this manner the difficulties of attack are increased, additional cover is given to the magazines or other buildings within the fortress, and the command over the country is increased and improved in efficiency, by elevating the soldier so that he can see over the many minor obstacles likely to restrict his field of view. A natural and simple mode of distinction may be therefore derived from the presence or absence of a rampart, and the two leading sections of the subject stated thus: parapet, or field fortification, and rampart, or town fortification.

In order to study efficiently the results of combining together these simple elements, and forming from them extensive works of defence, it is necessary that we should know the manner in which such works are represented on paper. As in architecture, of which in earlier times fortification was only a military branch, this is effected by the plan, the section, and the elevation, of which the two first are the most important. The plan of a work is the orthographic projection of the lines of intersection of the planes of its slopes on the plane of construction. The elevation is a similar projection on a vertical plane. The section or

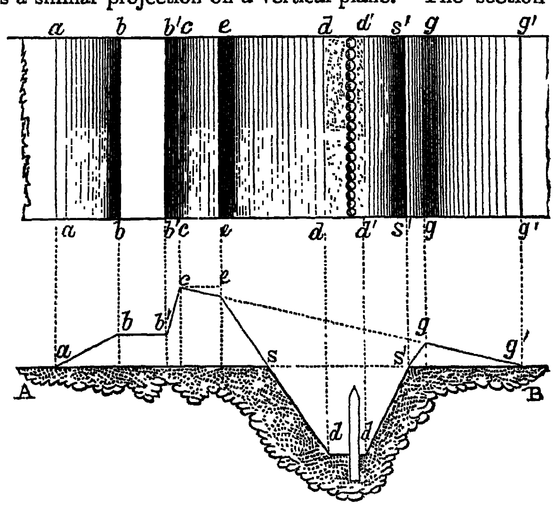

Fig. 1.

profile is taken on a plane perpendicular to the lines of intersection of the planes or slopes, and therefore represents

the traces of these planes on the sectional plane. Fig. 1 represents a small portion of a simple parapet in plan and profile, and leads to the following explanation of terms:—

In the plan, *cc* represents the crest of the parapet or highest ridge line of the work. In delineating the mere outline form of a work, it is this line which is always drawn, and is called the trace. Between *cc* and *ee* is the superior slope; between *ee* and a line parallel to it, through *s* of the profile, is the exterior slope, prolonged in this case to the bottom of the ditch *dd*, being continuous with the scarp *sd*; *gg*, crest of the glacis, or ridge of a slightly elevated mound of earth raised on the exterior edge of the ditch, or of the counterscarp, and sloping gently outward, so as to bring the assailants directly in the prolongation of the superior slope of the parapet, and therefore into the line of fire from its crest, and by its elevation to increase the amount of descent into the ditch. Within the crest of the parapet is seen the interior slope of the parapet, bounded by *b′b′*, the banquette, between *b′b′* and *bb*, and the interior slope of the banquette, bounded by *aa*.

Relief.—This term is adopted to show either the height of any point of the work above the plane of construction, which is sometimes equivalent to the plane of sight, and may then be called constructive relief; or the height above the bottom of the ditch, when it may be called absolute relief. The relief taken in the latter sense is a very important datum, as it expresses the total amount of the obstruction offered by the parapet and ditch to the ascent of the assailant, and also as it is necessary in regulating the length of lines, which mutually defend each other, as will be seen hereafter. Relief of a work refers to the relief of the crest of its parapet. Command of a work means the height of the crest of its parapet, either above the plane of sight if horizontal, or above any point of that plane specially referred to, or above the crest of the parapet of any other work in front of it; the difference of height, therefore, between the crest of the parapet in fig. 1 over the crest of the glacis is the command of the parapet over the glacis; in the one case it is absolute, in the other relative command. An examination of the profile figure brings also under consideration, in respect to the row of palisades, another simple principle, namely, that an enemy should be stopped as he advances to the parapet by every obstacle which can be thrown in his way, and thus kept exposed as long as possible to the fire either of the

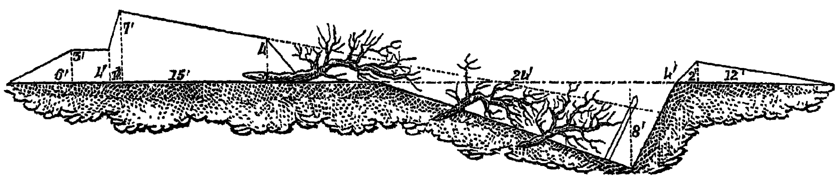

Fig. 2.

work in front of him, or of some other work taking him in flank; if simply opposed by a front fire from the parapet, palisades, arranged as these are, would only check for a very short time the progress of an enemy, and are more useful for gaining time on the part of the defenders than for ultimate defence.

Obstacles against approaches.

Many other obstacles may, however, be so arranged as to assist materially in rendering even the simple direct fire more effective.

Abattis.—These are formed of trees cut down, and arranged side by side with the branches interlaced together outwards, and the stems inwards; the branches should be freed from foliage, and their ends cut sharp. They may

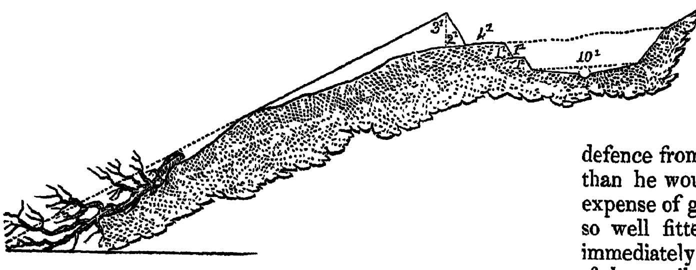

Fig. 3.

be arranged either in one or more rows, and when placed so that the fire from the parapet should sweep along their summits, they would, their stems being firmly fastened down by pickets to the ground and partly buried in it, occasion great loss to the enemy whilst attempting to remove them under fire.

Fig. 2 exhibits an arrangement of this kind; and it will be observed that on this profile the exterior slope of the parapet and the scarp have been formed into one gentle slope, whilst the counterscarp retains its ordinary slope. By this modification the difficulty of descending into the ditch remains as before, and the sloping pickets in front of the abattis prevents the assailants from immediately endeavouring to clear it away. In simple inclosed works, such as redoubts, as well as in lines, the defence frequently depends on direct fire alone; and in these cases an arrangement of the profile, as here figured with obstacles, would be far more effective in checking an enemy than an ordinary profile though in itself more difficult of ascent, without such obstacles, and in consequence would render it impossible that an ordinarily watchful garrison should be surprised; and this is a very important consideration, as a vigorous and bold enemy could scarcely be stopped if he had succeeded in arriving at the foot of the scarp unchecked.

Fig. 3 is another adaptation of an abattis formed only of large branches securely picketed down to the ground. In this case the form of the ground is taken advantage of, and even the profile of the defensive line is modified, a trench being cut out behind it, and the banquette being formed on the surface of the ground itself. The engineer will often, by simple arrangements of this kind, be able to carry his defensive lines over a large extent of ground in a short period of time, and to obtain a much more effective defence from the natural facilities afforded by the ground than he would have done by superadding to them, at the expense of great labour and much time, elevated works, not so well fitted to scour the face of the ground, and to act immediately upon the obstacles then checking the progress of the assailants.

Chevaux-de-frise.—The cheval-de-frise is an artificial substitute for an abattis. It consists of a strong horizontal beam, about 12 feet long and 9 inches square, through which

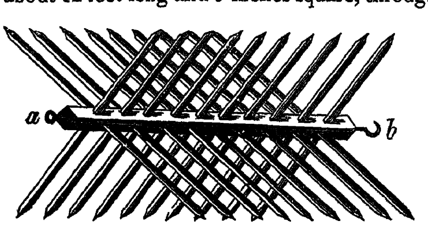

Fig. 4.

are passed strong lance-like rods of either wood or iron, sharp at both ends, and about 6 inches apart. Several of these

may be joined together by means of a ring at one end and the hook at the other end of the beam. The difficulty of making chevaux-de-frise, as their construction requires a number of carpenters and much wood, renders them unfitted for sudden emergencies, and they are also, under ordinary circumstances, easily removed or destroyed; but with these, as with all military implements, there may be opportunities of using them with effect. If planted at the bottom of a hollow, exposed to a well-directed fire, and so placed that they must either be pushed uphill forward or pulled uphill backward, and then secured to the ground, either by chains, or by being fastened to upright posts, they would often prove a formidable obstacle. They are more generally used as a barrier to close an open work.

Fraises.—The fraise is distinguished from the palisade by being fixed in a horizontal, or nearly a horizontal position.

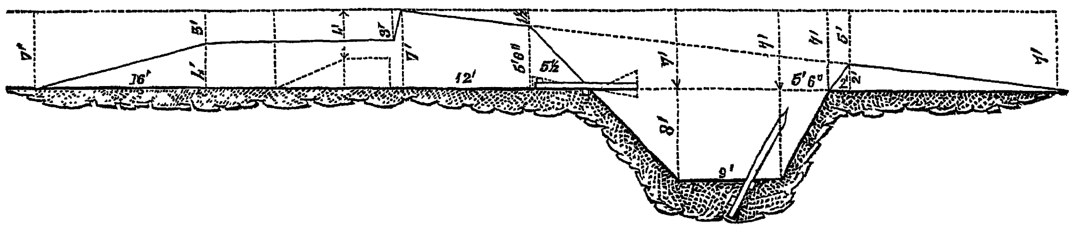

Fig. 5.

They are made about 10 feet long and 5 inches thick, being bound together by two ties, one nailed above and the other below them; without which precaution they would be much more easily torn away. They are sometimes fixed on the counterscarp as well as on the scarp.

Fig. 5 represents, in section, a row of fraises on the scarp. In this profile the ordinary banquette for musketry is represented by dotted lines below a wider terreplein formed for artillery to fire over the parapet, or a barbette, as it is usually called; but this will be more fully explained in a future paragraph.

Chausse-trapes.—These are made of four points of iron so arranged that one should always project upward in whatever manner they may be thrown on the ground. The points are either 2 or 4 inches long, and they are *sown* over a space about 12 feet broad. Without doubt, troops coming suddenly, and in the dark, on such obstacles as these, would be much annoyed by them; and, in consequence, they were formerly much used, more so than they are now.

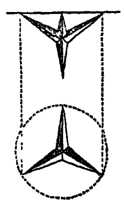

Fig. 6.

Trous-de-loup, or wolf-traps, are holes made in the ground in the form of a truncated cone, the sides of which are as little sloped as is consistent with the stability of the soil. They are made from 5 to 6 feet deep, and 6 or 8 feet in diameter. At the bottom a sharp picket is fixed, from 3 to 4 feet long, or, in place of it, the branch of a tree cut into sharp points, or a number of smaller sharp pickets, or a quantity of chausee-trapes. The figure shows the arrangement of trous-de-loup proposed by Wênzêl, in plan and in section. If along the defensive line of a position, either on the glacis or on the scarp, when gradually sloped as in fig. 2, small trees or shrubs are planted, and on an emergency cut down, and the points of their stumps sharpened, they become very annoying to an assailant. Harrows have also been used, and, in short, every expedient which ingenuity can suggest should be adopted by an engineer to check the progress of an advancing enemy, and to keep him as long as possible under fire.

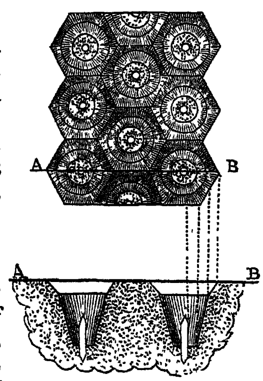

Fig. 7.

Stockades.—Before proceeding to an investigation of the principles which should regulate the relief and thickness of ordinary parapets, viewed in reference to simple defensive lines and to direct fire, it is right to notice the stockade as a substitute, and in some circumstances an advantageous one, for a parapet. The stockade is formed of either one row of stout palisades, or two rows, one behind the other; and the following is one of the simplest modes of constructing it:—

A row of very strong palisades, pointed at the top, from 8 to 12 inches square, is formed, with intervals of 3 inches between every two palisades, and behind this row is formed another corresponding to the open intervals in the first. These second palisades are only from 5 to 7 inches thick, and are cut square at the top, every second one being cut short, or to the length of $4\frac{1}{2}$ inches, so as to fire over it as through a loophole. This stockade is shown in plan, elevation, and section; it has a banquette of earth, which may be replaced when desirable by a wooden step. By cutting out the triangular portion shown in the section, and throwing the earth up against the front of the palisades, an exterior slope and scarp are formed which keeps an enemy constantly in view. Such a stockade as this brought up close to the edge of a steep bank, requiring defence, has a great advantage over a parapet, as the men behind it have a much more effective command of the ground before them when firing through the loopholes than they could possibly have when firing over a parapet. It is here supposed that artillery fire cannot be brought to act in front against the stockade, but it may possibly be brought to act against it in a longitudinal, or, as it is called, enfilade direction; and in this case the line of stockades should be interrupted by traverses, which are usually banks of earth placed transversely to the line they are intended to protect from enfilade fire.

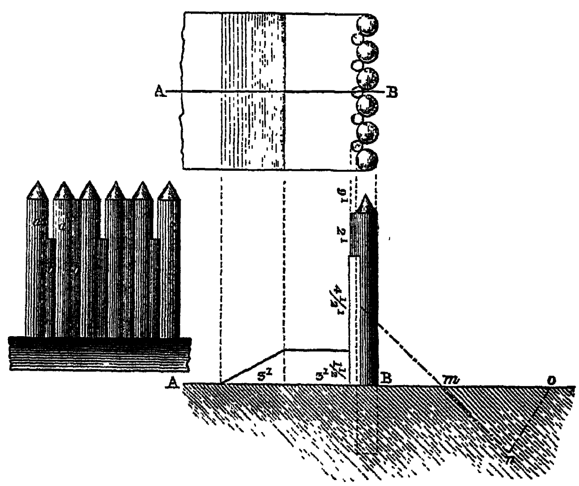

Fig. 8.

Fig. 9 shows the adaptation of a stockade of this description to the defence of precipitous ground. When stockades

are formed into inclosed works, they constitute what are called "tambours."

It may in a similar manner be desirable to throw an ordinary parapet forward to the edge of a bank, the slope of which supplies the function of a scarp, and hence to dig the ditch behind instead of before it, as in fig. 10, where it will be also observed that the slope of the banquette is broken into two steps, the tenacity of the earth when first excavated allowing it to stand firm; and the principle of this excavated form of structure is also adopted in sunken batteries.

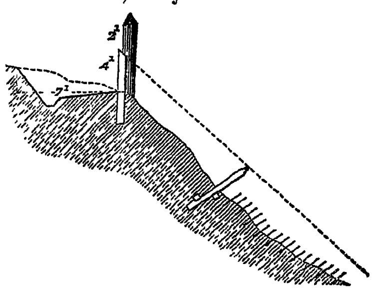

Fig. 9.

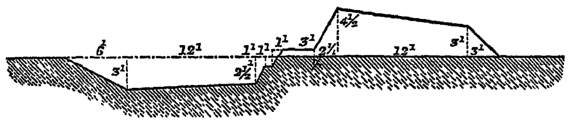

Fig. 10.

Sometimes the object of the parapet is merely cover and not active defence, in which case the banquette is omitted as in

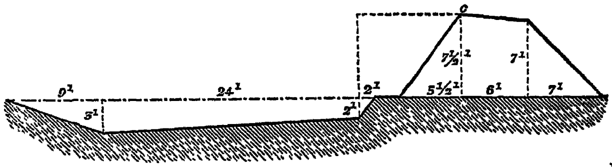

Fig. 11.

fig. 11; and the work is called an epaulement. In this profile it will be observed that a space is left between the face of the epaulement and the internal ditch, which is called a berm. Such a space should always be left, whether the ditch is within or without, when the work is to be formed of any considerable elevation, as it forms a stage upon which the builders can stand, and lessens the height to which the diggers have to throw the earth from the ditch; and it is very important to keep the berm clear by throwing forward or back the earth as quickly as it is raised. The distinguish-

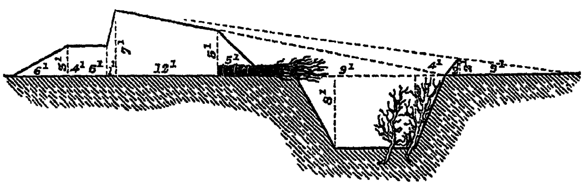

Fig. 12.

ing characteristic of an able engineer is to be found in the power of varying his appliances at will;—thus the abattis may become the fraise, or may displace the palisade, as in fig. 12. Were this principle not kept in view, more evil than good would sometimes result from systematic instruction; as the person who had acquired a knowledge of some one

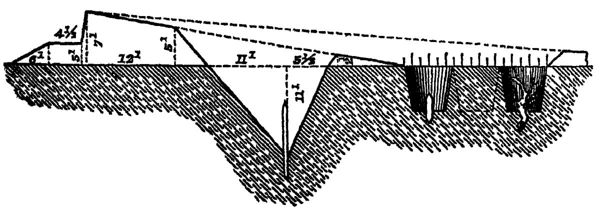

Fig. 13.

contrivance might be found crippled by his constant efforts rather to conform to it than to look about him for some other better fitted for the existing circumstances. In this profile a berm is represented, as it would be difficult to arrange the abattis, and to build the parapets without it.

The arrangement of the trous-de-loup, combined with stakes driven into the ground, is shown in fig. 13, an advanced glacis having been formed of the earth thrown out of the excavations. The ditch is in this case triangular; and it is scarcely necessary to add that the choice of any particular form must be determined by the engineer from a knowledge of the nature of the ground itself, only remembering that the contents of the ditch, or ditches, must supply material for forming the parapet; and further, that as its depth adds to the difficulty of assault, it should not be diminished except from necessity. After these elementary remarks, the student may be considered prepared to enter on the consideration generally of parapet or field fortification.

RULES FOR DETERMINING THE DIMENSIONS OF PARAPETS.

Determination of the Relief of a Parapet.—First, in respect to the protection of troops in a normal position, where the ground is considered horizontal. Now, the minimum for a simple parapet may be here stated at 6′ 6″ as a musket ball would penetrate the parapet for about 6″ below its crest, and the maximum at 8 feet, a height which gives the defenders perfect security under almost every circumstance of fire, including even that of mounted soldiers.

Defilade.—Secondly, where the ground is uneven, and it is necessary to defilade the work from the point or points which command it. Now, figure 14, No. 1, explains the first case in which the points A, B, C, are on the same level, the distance AB being the space intended to be protected by the parapet at C. The line CF represents the supposed height at which it is presumed the assailants may fire, or in this case 8 ft.; BE will be the same; and AD cut by the line drawn from F to E will also be 8 ft. In fig. 14, No. 2, A, B are still considered to be in one horizontal plane, but C is considerably elevated; and hence, adopting the same data as to height, and drawing the line FE and the line CB parallel to it, AD, or the height of the parapet, equal to AI + ID; ID being equal to BE, or CF, or N, the normal height. Calling also AB, or the distance to be covered, d; AH, or the distance from the commanding point, D; HC, or the height of C above A and B, H; we have AI : CH :: AB : BH; or AI : H :: $d : d + \mathrm{D}$; and hence

$$\mathrm{AI} = \frac{d}{d+\mathrm{D}} \cdot \mathrm{H}, \text{ and } \mathrm{AD} = \mathrm{N} + \frac{d}{d+\mathrm{D}} \cdot \mathrm{H} \qquad (1).$$

So that the necessary height of the parapet increases as the height of the commanding point increases, or as the distance AB to be defiladed increases; and diminishes as the distance from the commanding point increases. Taking $\mathrm{D} = 600$ ft., $d = 30$ ft., $\mathrm{H} = 60$ ft., $\mathrm{AI} = \frac{60}{21}$, or 2 ft. 10 in., and AD, or the height of the crest of the parapet, equal to 8 ft. + 2 ft. 10 in. = 10 ft. 10 in.; or taking D = 1200 ft., or 400 yards, AD = 9′ 6″.

Fig. 14, No. 3, represents A lower than B by a quantity = AO = GH = h; hence AD = AO + OI + ID, and

$$\mathrm{OI} = \frac{\mathrm{OB{\cdot}CG}}{\mathrm{BG}} = \frac{d}{\mathrm{D}+d}(\mathrm{H}-h), \text{ or } \mathrm{AD} = \mathrm{N} + h + \frac{d}{\mathrm{D}+d} \cdot (\mathrm{H}-h) \quad \ldots\ldots\ldots\ldots \quad (2);$$

an equation which shows that the deeper A is sunk below B and C, the more elevated must be the parapet, and hence that this is a very unfavourable condition of parapet. For example, let A be 2 ft. below B, and all other data the same, $\frac{d}{\mathrm{D}+d} \cdot (\mathrm{H}-h) = 2$ ft. 9 in., and AD = 8 ft. + 2 ft. 9 in. + 2 ft. = 12 ft. 9 in.; or when D = 1200 ft.,

11 ft. 4 in.; and if it should be necessary to defilade a distance of 90 ft. instead of 30, the heights of the parapet would necessarily become 18 ft. 8 in., and 14 ft. 2 in.

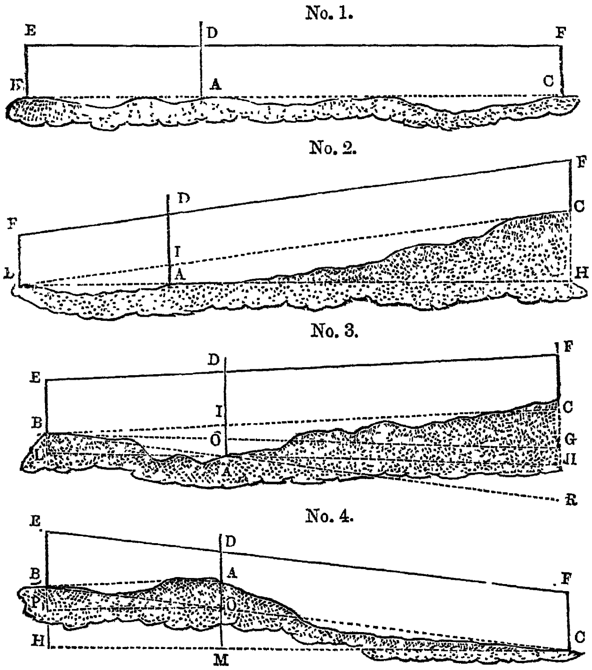

Fig. 14.

Again (fig. 14, No. 4) in this figure A is higher than B, or than C, which is the lowest of all; and if H still represents the difference of level of A and C, and h the difference of level of A and B, $AD = N - h - \frac{d}{D+d}\cdot(H-h)$ . . . (3); and, of course, so far as concerns the height alone of the parapet, this is the most favourable condition of all.

Any other case is easily resolvable by one or other of the formulæ;—thus, when A and C are on the same level, and B higher than A, H becomes O, and No. 2 becomes $AD = N + h - \frac{d}{D+d}\cdot h$.

And in No. 3, if B be higher than A, it becomes positive, and $AD = N + h - \frac{d}{D+d}\cdot(H+h)$ . . . (4); or if h be 0, A and B being on the same level, $AD = N - \frac{d}{D+d}\cdot H$.

In equation (4), if the station C, though below A and B, falls between the horizontal line drawn through A, and the line BR or BA be prolonged till it cuts the surface of the ground, sloping from B towards D, then $\frac{d}{D+d}\cdot(H+h)$ is less than h, and AD is greater than N; but should C be below the line BR, then $\frac{d}{D+d}\cdot(H+h)$ is greater than h, and AD is less than N; or, in other words, if the line of defilade passing through BA meets the ground at R within the prescribed limits of defilade, or the effective ranges of musketry and artillery, which may be now assumed as 500 yards for the first and 1000 yards for the second, if the point C be above that line the parapet at A must be made higher than the normal height, and if below it may be made lower. A comparison between the numerical results attached to equation (2) will exhibit the great disadvantage, to the defenders of simple lines, of having any ground near to their own moderately elevated, and care should be therefore taken either to occupy the ground or to throw back the lines opposite such eminences as far as possible, and should it have the character of a ridge, to bring some portion of the fire of the line to act in the direction of its length. The space AB to be defiladed must depend upon circumstances, but the minimum to allow for a safe communication for the troops behind and actually defending the parapet ought not to be taken below 30 feet, and where troops are required to be drawn up behind the parapet at 90; but in cases of double lines or of inclosed works the distance must of course vary, as the object will then be to protect not only the troops nearest to the enemy from a direct fire, but the troops arming the more distant parapet from a reverse fire. In assuming the normal height as 8 feet, on the supposition that the fire might proceed from mounted soldiers, a condition is adopted which is not generally likely to occur in the attack of intrenchments: if, however, the normal height were assumed at 7 feet, the space behind the parapet must be very imperfectly defiladed, as the trajectory of the ball, being in its descending curve, will come to the ground at a much nearer point than in the original supposition of a straight line of trajectory; and hence it is desirable to adhere to the normal height of 8 feet. In equation (3), and in one case of (4), as explained, the height of the parapet becomes less than N, but should the diminution extend so far as to reduce the height of the parapet below 7 feet, the absolute relief should be restored to its proper amount, or to 7 feet, by excavating the ground behind the parapet, or, in other words, forming a terreplein below the level of the plane of site. In a similar manner, in respect to equation (2), and in one case of (4), where the parapet becomes greater than N, it would be very inconvenient to augment the height above 12 feet, and it is preferable therefore to excavate behind the parapet, whenever the defilade requires so great an increase of height.

Flanking or reciprocal defence.

In the preceding observations the parapet has been considered as forming a simple continuous line, deriving its defence solely from its own direct fire; but such a condition would most frequently be found inapplicable, even as regards form, in consequence of the natural inequalities of the ground, and, with few exceptions, unsatisfactory, as regards defence, in consequence of the imperfect operation of direct fire from the top of a parapet, which can only be brought to bear upon some external line, and must therefore leave the foot of its scarp unseen and unprotected, after an advancing enemy has come within the limiting line of defence. A fire, therefore, so directed as to take the enemy *in flank* has been adopted, and a line or work is therefore said to be flanked when some portion either of its own parapet, or of the parapet of another work, has been so arranged that the fire from it shall take an enemy advancing towards the other portion in flank. In lines of intrenchments this arrangement leads to a bent line, having angles projecting *towards* the country called *salient angles*, and angles retired *from* the country called *re-entering angles*; and it is evident that in this arrangement (fig. 15) the lines AB and AC, which are flanked by BD, CD, do in their turn flank BD and CD, and that flanking defence may therefore be called *reciprocal defence*, a term which more accurately defines its object and value.

Referring back, then, to the subject of defilade, it is evident that a bent line of this kind affords more facility for defilading than a straight one, as it is often possible so to arrange the position of the angles that the salients shall occupy high points of ground, while the re-entering angles though placed on lower shall be compensated for this defect by being further removed from the commanding ground of the enemy.

Enfilade fire.

Whilst a simple straight line has the disadvantage of depending for its defence solely on direct fire, it has the advantage of not being exposed to a fire from the enemy so directed as to sweep along its whole length from one end to

the other, a fire which is called *enfilade* fire, and is necessarily very destructive, as it produces the same effect in

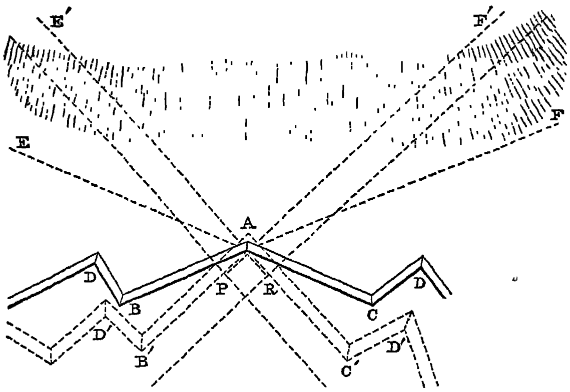

Fig. 15.

attack as a flanking fire in defence, by taking the defenders of the line in flank. To guard against this evil, should it be indispensable to take up a position in front of ground of a superior command, the long lines AB, AC should at least be so directed that their prolongations should fall in low ground at EF, and not as they would do in the case of AB′, AC′, on the high ground at E′F′; and of course, if possible, and where the high ground is not continuous, that the prolongations of both short and long lines should fall on the low ground between the commanding eminences, an arrangement which will be more especially beneficial should the low ground be marshy or otherwise difficult of occupation by an enemy. Such observations as these can only be suggestive, since no fixed rules can be laid down for an engineer in such cases, as he should look at his ground and adjust his works so as to make the most of the natural advantages it presents, and to neutralize, as far as possible, the ill effects of any disadvantages it may possess. To determine the height of the parapet by defilading in the manner stated, it is necessary to have a correct plan of the ground, and to know the exact levels of the points A, B, C, in every case; but the defilading may be effected by levelling poles or boning rods where there is no such plan. In this case the inner boundary of the ground within the parapet required to be defiladed being staked out, a boning rod of 7 or 8 feet high, according to the intended normal height of the parapet, should be placed at BC, on the staked-out line, and another of equal height on the commanding point or ground, fig. 16, supposed to be either at or within the range of the projectiles against the fire of which the work is to be secured. A rod about 12 feet high is then fixed at A, and a cross-piece or marker, as in levelling staves, is raised up or down until it meets the point where the visual line from the top of B to the top of A intersects the pole at A; so that this operation is simply the mechanical determination of the height obtained in the other method by calculation. If it be required to defilade the whole space between two parallel lines, or that included between the two lines forming the salient angle in fig. 15, it is evident that the work must be defiladed from both sides, and further, that the soldiers standing on the banquette of one line should be secured from the fire of the ground in front of the other, or from the fire called "*reverse fire*," as taking them in rear. This is effected by placing a mound of earth or traverse between them, and determining its height as well as the height of the parapets in the following manner:—On the commanding point C is placed the boning rod CD of the normal height, and

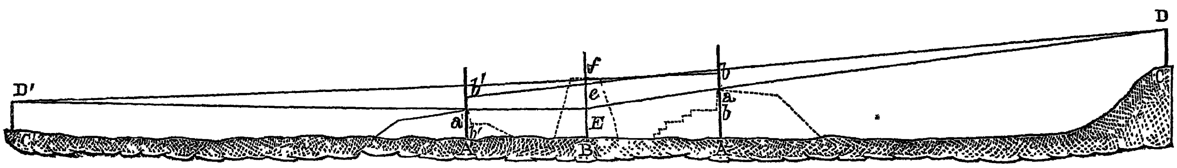

Fig. 16.

another BE, at B, or at the position of the traverse of the same height; then the height of the crest of the parapet of A is determined by the intersection of the visual line from D to E with the pole fixed at A, at the point *a*, which is here high, as C is so much higher than A. See preceding rules and equations. In like manner a pole of the proper height being fixed at the extent of range on the opposite side at C′, the visual line from D′ to E determines the height of the parapet of A′ at *a*′, which is much lower than the parapet of A, as A′ and *b*′ are nearly on the same level. Now, to defilade the banquettes, and to determine the height of the traverse necessary for that purpose, set up on the banquette of A a pole *bb* of the same height as CD, C′D′, BE, and the visual line from D′ to *b* determines the height of the traverse at *f*, which is necessary to secure the banquette of A from the reverse fire of C′, whilst the visual line drawn from D to *b*′ determines the height of the traverse sufficient to protect the banquette of A′ from the reverse fire of C. The application of these principles is shown in reference to a work formed of two lines (or *faces* as they are called), terminating in a *salient* angle, by fig. 17; whether that work is connected with a line of intrenchment as in a *redan*, or is detached as in a *ravelin* and other outworks, or forms part of a peculiar system or arrangement of works as in the *tenaille* system of Montalembert, called by its author the angular system; terms and works which will be hereafter more fully explained. Here the commanding point is supposed to be at M, and to secure the defenders of the face AB from a reverse fire, it is necessary to interpose the traverse *cd*, called from its object a *parados*. The length of the traverse *cd* is determined by the line MB, beyond which it should project

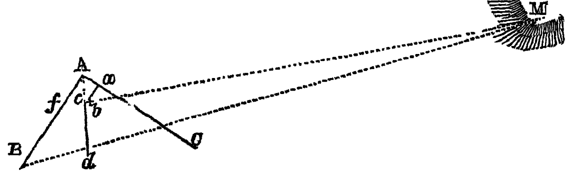

Fig. 17.

sufficiently to give ample security to a space about 50 feet wide behind the parapet. At the other end, the traverse is not carried up to the salient angle, as it would interfere with the communication, but is completed by *ba*, perpendicular to the other face, by which arrangement the space within the salient and the banquette are left free. The two lines M*d*B, and M*cf*, will be directed to points raised above the banquette by the normal height assumed, whether 7 or 8 feet, and thus determine the height of the traverse. It may, however, happen that the commands are so situated as to produce an enfilade fire along both the faces AB, AB′; fig. 18. In this case a small work is formed DAD′ in connection with the parapet, by drawing lines parallel to the crest of CB and C′B′ at a distance from it equal to the breadth of the banquette, and then determining, in the manner explained, the height of A necessary to defilade a certain length of the banquette of CB and C′B′ sweeping

Bonnet.

it, and assuming the greatest of the two as the height of the parapet at A. This work is called a *bonnet;* and when the height necessary to defilade the whole of one or both faces is found to exceed 12 feet, the height of A should be restrained to that limit, and traverses, T, T', T^2 be placed at such distances as shall cause a complete defilade without exceeding the height of 12 feet.

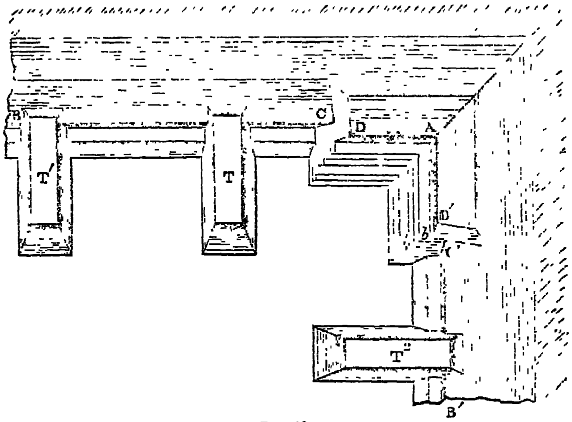

Fig. 18.

The internal space may frequently be sufficiently defiladed by raising the salient portion of the parapet without disturbing the line of direction of the crest; but in that case the banquette of the two faces would not be covered from the enfilade fire, and hence the necessity of a bonnet. The increased height of the parapet of the bonnet renders

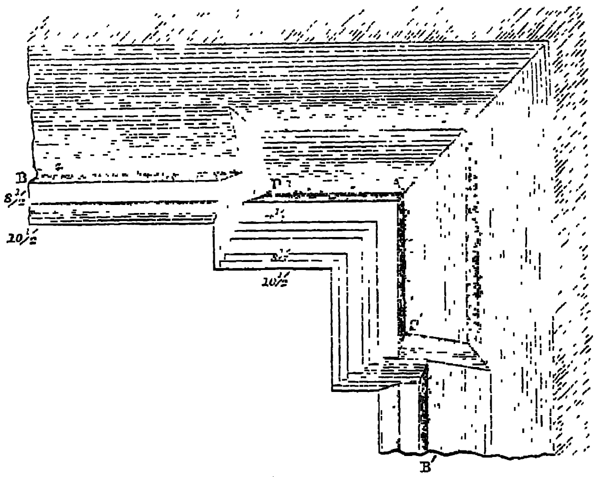

Fig. 19.

it necessary to adopt two banquettes *b*, *b'*, one below the other, and each provided with steps to facilitate ascent, fig. 19. The operation of defilading may be also effected by *planes* of defilade; as, for example, if the line which marks out or limits the space to be defiladed be first drawn, and a plane be supposed to pass through a line either 6 ft. 6 in. or 8 ft. (or whatever height between these may be assumed as the normal height N) above the limiting line, and through a point the same height above the commanding point, this plane will determine the height of the parapet, the crest of which will necessarily be in it. Practically it may be done thus: On the boning rods marking the ends of such portion of the limiting line as can be included in one operation, mark the normal height N considered necessary, and then remembering that a vertical plane through the boning rods would necessarily intersect the defilading plane in a straight line, place one edge of an equilateral-triangular frame of wood in the intersecting line by directing it to the marks on the boning rods, and then attach the frame in that position to an intervening rod. The base of the triangle will now be in the defilading plane, and by moving the triangle on the base as a hinge until the mark on the boning rod at the point of command is just seen along the surface of the frame, it is evident that the triangle itself will then be in that plane also. Fixing the frame in this position, it is only necessary to look along its surface in any direction in order to mark on the boning rods set up on the line of the crest of the parapet the necessary height at each point.

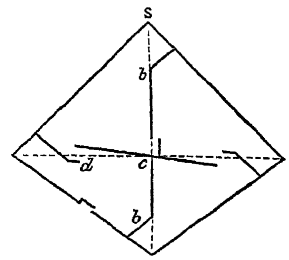

Fig. 20.

Where the parapet is continued not only on the flanks but also in the rear, so as to form an inclosed work, it may often be necessary to defilade it in various directions as in fig. 20. Where two traverses or parados cross each other, they must, of course, be so placed that they shall not only complete the defilade of the whole interior space of the work, but secure from reverse fire the banquette on each side, the normal N being therefore, at least, 6 ft. 6 in. above the banquette. Where traverses of this kind become necessary, the engineer must take into account the space they will occupy, and plan his work accordingly; and should he be able to render the difficulty of attacking one side of his works very great, he may so construct one or more of the traverses that they may be used as retrenchments, and thus increase the means of defence; for example, S being the salient of greatest strength, *bcb* might be first defended, and then *bcd*.

This subject has been enlarged upon because it is one of the most important in engineering, as the safety of a long line of works may be endangered by defective defilading. Though exhibited here in a practical form, it depends essentially on geometrical principles, and instruction therefore in descriptive geometry is now considered essential in all schools of military engineering.

Dimension of profile.

Having determined the relief of the crest of the parapet in reference to the plane of site, all the other vertical dimensions depend upon it, as shewn in several of the preceding figures; whilst the horizontal are regulated either with regard to the slopes required to ensure stability, or the thickness necessary to resist the enemy's missiles. For example, it has been determined that the penetration at a mean range in common earth, after having been dug up and well-rammed, and the thickness for security, are as stated below:—

Weapon.	Penetration.	Required thickness for security.
Musket.	1 ft 6 in.	3 ft.
6-pounder.	3 6 to 4 ft. 6 in.	6
9 „	6 6 to 7 6	9
12 „	8 6 to 10 0	14
18 and 24 pounder	11 6 to 13 0	18

But as neither the 18-pounder nor 24-pounder is now often brought into the field, the thickness of parapet has been usually assumed to be 14 ft. In the Austrian service, in which, as in the Russian, the 18-pounder is a recognised field-gun, it is usual to allow the following thicknesses:—

		Feet.
For defence against	Musket balls	4·3
„	3-pound shot	4·6
„	4 and 6 pound	8·6
„	8 and 12, and 7 and 10 pound howitzers	13·0
„	18-pounder shot	16·6

With light, sandy, or gravelly soil, or, when tamping can only be imperfectly performed, a greater thickness ought to be allowed; and, as the presence of a wide and deep ditch must always materially strengthen the work before which it is placed, there can be no other reason than want of time, want of men, or difficulty of ground,

for reducing the thickness of the parapet below 14, or at the utmost 12 feet. If wood be used, the same authority gives us the necessary thickness for resisting musket balls at from $5\frac{1}{4}$ to $6\frac{1}{4}$ inch; against 3, 4, or 6 lb. shot, 3′ 3″ to 4′ 11″; against 8 and 12 lb. shot, or 7 and 10 lb. shells, 4′ 9″ to 5′ 4″; and against 18 lb. shot, 6′ 6″. Brick walls from 2′ 8″ to 3′ 3″ thick; and rubble walls from 3′ 3″ to 3′ 10″ will resist field-guns. For forming the parapet under peculiar circumstances of difficulty the engineer will avail himself of every fitting substance which may be at hand; such as bags of wool, mattresses, fire-wood, manure heaps, as well as fascines, either by themselves or packed in gabions. Of these latter substances the resistance is not great, the penetration in wool being double that in rammed earth, and the strength of fascine works being rapidly diminished by the speedy fracture of the branches when exposed to a sharp fire.

With these data it will be easy to regulate all the dimensions of the parapet, the height of its crest, or the relief of the work, having been first established. Thus the plane of the banquette or step on which the men stand, when firing over the parapet, should for convenience be 4′ 3″ below the crest, and on no account should exceed 4′ 6″. The breadth or tread for a single rank should be 3′, for a double rank 4′ 6″; the surface should slope backwards 2 or 3 inches in the 3′—3 or $4\frac{1}{2}$ inches in the 4′ 6″, so as to discharge water freely and keep the banquette dry; the base of the interior slope of the banquette up which the men mount should be twice its height; if the height of the parapet exceed the normal height, it will be desirable to form two treads or steps to the banquette, the lower about seven feet below the crest, so that one rank of men may stand there whilst reloading the muskets of those in advance of them; or, to adopt steps with a rise to each of 1′, and a tread of 1′ or $1\frac{1}{2}$″, sloping slightly to the rear, by which arrangement the necessary excavation of the ditch will be diminished, and less of the interior space occupied. The interior slope of the parapet should be 1′, or a base of 1′ to 4″ of the height, and should never exceed a slope of 1 to 3—the superior slope or *plongée*, of the parapet, by which the fire is directed towards the point on which it is to act, should not be less than $\frac{1}{9}$, nor more than $\frac{1}{4}$ of its thickness, and in service is generally made $\frac{1}{6}$; but as the increase of the slope facilitates the destruction of the crest, it should be kept as small as possible; and it is usual on the continent to retain the angle of the crest as a constant quantity, at 100°, and hence to increase the base of the interior slope as the plunge increases, and *vice versa;* but this is not satisfactory, since the height of the soldier's shoulder remaining constant, whilst the direction of the prolongation of the line of plunge varies, the fire will not be always in the true direction; and it seems therefore preferable to keep the base of the interior slope as small as possible, and to make the top of the parapet at the crest horizontal for one or two feet, commencing the plunge at that point, and bringing it inwards in proportion to the increase of plunge. This flat space will facilitate the use of sand bags (bags filled with earth), which are sometimes so arranged on the crest of the parapet as to form loopholes for the musketry, whilst they add to the cover of the men; the base of the exterior slope of the parapet is equal to its height, in earth of a medium tenacity, so as to form an angle of 45°; and in some particular cases where the materials would naturally stand at a steeper slope, it may be made $\frac{2}{3}$. The bases of the slopes of the scarp and counterscarp of the ditch, as being cut in undisturbed ground, need not exceed $\frac{1}{2}$ of the depth as a general rule, though occasionally in very loose ground the slopes will require to be as gradual as in the exterior slope, or slope of made ground, in order to insure stability. Where steeper slopes are deemed indispensable, the earth must be supported in place by a retaining coating (or wall) called a revetement, which may be formed of *fascines* (long cylindrical bundles of faggots), hurdles, sods, planks, clay puddling, and, in interior works, of sand bags. The base of the interior slope of the glacis should be equal to its height, and the exterior slope have a plunge of 1 foot in 12. The command of the crest of the parapet over that of the glacis should be such that an assailant, having arrived on the crest, should not be able to fire into the interior of the work: a condition which requires a command over the glacis of $5\frac{1}{2}$ feet, so that with a parapet of 7 feet high the *maximum* height of glacis would be $1\frac{1}{2}$ feet. The minimum height of the glacis is determined by another condition, viz., that the fire from the parapet should be in a plane not more than 2 feet above the surface of the glacis; and in no case should the plunge or slope of the glacis be greater than that of the parapet. An advanced glacis is sometimes adopted either for rendering the cover more effectual, or to occupy a favourable line for first opposing the progress of the enemy. Fig. 21 shows this arrangement, g, g' being the first or ordinary glacis, and g^2, g^3 the second or advanced glacis. The slope of neither glacis should be such as to withdraw the assailants from the grazing fire of the parapet, and if it be not possible to extend the slope of $g^2\,g^3$ so far as to keep it in the prolongation of the line $C - g^2$, it should be at least so arranged that no point of the slope should be more than 2 feet below that line or the plane

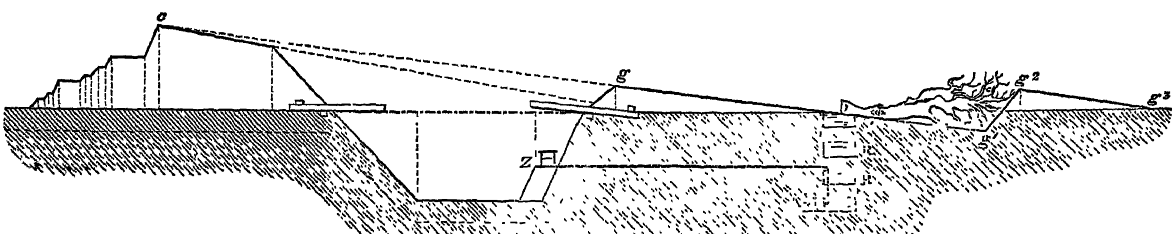

Fig. 21.

corresponding to it, namely, the plane passing through the crest of the parapet and the crest of the advanced glacis. To form the advanced glacis, the slope at g is prolonged below the surface of the earth to g', the excavation supplying material for the raised glacis. When it is intended that the defence of this advanced glacis shall be derived solely from the parapet, either an abattis or rows of stakes may be placed immediately behind it, so as to stop the advance of the enemy when at the point of maximum exposure, but such glacis may often assume the character of successive intrenchments, and be defended with vigour and success. This figure will be again referred to when treating on defence by mines. The height or relief of construction of the parapet having been determined by the amount of cover required, and the thickness by the nature of projectile expected to be brought against it, the whole profile or section has necessarily been completed on the principles pointed out, and the bulk, therefore, of earth contained in any portion of the parapet will be equal to the area of the mean or average profile multiplied by the length of that portion. Now, this earth must be obtained from the ditch, and hence the dimensions of the latter depend on those of the former,

whilst at the same time the volume of any portion of the excavated ditch will also be equal to its mean section multiplied by the length of that portion. If, then, P represent the area of the mean section of this portion of the parapet, D the area of the mean section of the corresponding portion of the ditch, and L the length of this portion, LP should be $=$ LD, providing the earth of the excavation were of the same bulk as after it; but such is not the case, and after having been broken up from its previously closely packed condition, it is found that the "remblai" or earth built up exceeds the "deblai," or earth excavated by a co-efficient varying with the nature of the soil, being in sandy soil nearly 0. Thus if $\frac{1}{m}$ represent the coefficient, it is in sand 0; in earth of medium tenacity $\frac{1}{12}$; and in very strong and naturally compressed earth $\frac{1}{6}$; so that to render the earth of the ditch just equal to that of the parapet, the above equation should be $LP = L\left(D + \frac{1}{m}D\right)$ and $P = D + \frac{1}{m}D$, or $D = \frac{m}{m+1}P$. As, however, the earth resulting from this excess, even allowing for the greater length of the ditch in polygonal works, will be required for forming the glacis, or for making up the banks in the salient called "barbettes," and intended for raising guns sufficiently high to fire over the parapet, the dimensions of the ditch may be safely estimated without reference to the excess, as follows:—

Let x be the breadth of the bottom of the ditch, and y its depth; and let the sum of the bases of the slopes of the scarp and counterscarp be represented as a function of the depth by the fraction $\frac{r}{s}y$; then $x + \frac{r}{s}y$ will be equal to the breadth of the ditch at top, and $D = \frac{y}{2}\left(x + x + \frac{r}{s}y\right)$ whence $x = \frac{D}{y} - \frac{r}{2s}y$, and $y = \frac{s}{r}\left(-x + \sqrt{x^2 + \frac{2r}{s}D}\right)$. Now as the defensive object of the ditch requires that it should be both deep and wide enough to form a decided obstruction in the way of an enemy, the width ought not to be less than 18 feet, whilst the depth should have no other limit than that arising from the difficulty of raising the earth which makes 12 feet about the maximum. Taking then $y = 12, \frac{r}{s} = \frac{3}{2}$, and $D = 108$ superficial, $x = 9 - 9 = 0$, and the width of the ditch therefore $= \frac{2}{3}$ of $12 = 18$; the ditch being triangular.

Assuming a profile area of 70, corresponding to a parapet 7 feet high and only 6 feet thick, and making $x = 0$ for a triangular ditch, $y = \sqrt{\frac{2s}{r}D} = 9'\ 7''$, and the width of the ditch $= 14\frac{1}{2}$ feet: with a profile area of 116 feet corresponding to a parapet $7\frac{1}{2}$ feet in height and 12 feet thick, the depth of the ditch, if triangular, is $12\frac{1}{2}$ feet and its width $18\frac{3}{4}$; so that this profile appears about the maximum for a triangular ditch with a profile area of 163 feet, corresponding to a parapet 8 feet high and 18 feet thick. With a banquette $4\frac{1}{2}$ feet wide a triangular ditch would give $y = 14\frac{3}{4}$ feet, so that such a form would be inconvenient; but taking $x = 4$ as the width of the bottom of the ditch, y or the depth becomes $12'\ 4''$, and the width of the top of the ditch $22\frac{1}{2}$ feet—a very well-proportioned ditch.

In the preceding cases the base of slope of the scarp has been assumed as equal to its height, and that of the counterscarp slope as half the height. Should the nature of the soil be such as to require the base to be equal to the height in both scarp and counterscarp, $\frac{r}{s}y = 2y$; and where the soil is sufficiently firm to admit of a base of one-half in both, $\frac{r}{s}y = y$. In the first of these cases even the large profile area last named may be made triangular with a depth of $12\frac{1}{2}$ feet, and breadth of 25; and in the second a triangular ditch is inadmissible even with an area of 116 feet, as it would require a depth of more than 15 feet; and it could only be used with profile areas up to 85 superficial feet, for which a depth of 13 feet would be required. Before leaving this subject, a few words may be said respecting the "berm." The most effectual scarp in respect to defence is that which forms one continuous plane with the exterior slope, or at least which commences immediately where the other ends, as the absolute relief of the parapet is therefore made a maximum, and there is no berm; but in many cases it would be imprudent to carry the parapet up to the edge of the scarp, as the latter might be easily injured and occasion a fall of part of the parapet, and further, the difficulty of construction would be greatly increased by having no intermediate stage between the bottom of the ditch and the top of the parapet. The "berm" or step between the top of the scarp and bottom of the parapet is made from 2 to 4 feet according to the nature of the ground, and it then becomes possible in most cases to increase the slope of the scarp to a base of $\frac{1}{2}$ or $\frac{2}{3}$, at least to such a slope as shall bring the prolongation of the exterior slope of the parapet to the base of the scarp. The berm is encumbered with such obstacles as shall prevent an enemy from making it a halting place (see fig. 12). The slope of the counterscarp is usually $\frac{1}{3}$, $\frac{1}{2}$, or $\frac{2}{3}$, when that of the scarp is $\frac{1}{2}$, $\frac{2}{3}$, or 1; and it should be added that the bottom of the ditch ought always to slope on each side towards the centre, so as to carry off the water, and that it should be so arranged as to prevent the enemy from collecting together, and reforming his men in the ditch which in all cases of simple lines, without flanking defences, he would do were the bottom left free from obstructions.

APPLICATION OF THE PARAPET IN COMBINED OR RECIPROCAL DEFENCE, CONSTITUTING PARAPET OR FIELD FORTIFICATION.

The parapet has been hitherto considered principally in its character as the simplest element of defensive works, affording at once protective cover to the soldiers behind it and an obstruction to the advance of their enemies; but it is now time to consider the manner in which this parapet may be so arranged as to constitute a series of defensive and mutually defending works. Were the antiquity of an invention to be estimated in reference to an epoch in the social history of any race of mankind rather than to a point in absolute time, there can be little doubt that earth-works would, as might be naturally expected, claim the priority over all other modes of defence. In North America vestiges of circular intrenchments, as well as of works of a more complicated outline, have been discovered, the antiquity of which is unknown; and even now, when a small party of the aboriginal inhabitants have been suddenly encountered by a much greater number of a hostile tribe, they have been known to excavate a hollow space in the ground, and, throwing out the earth, to form around them a circular intrenchment, in which they have defended themselves to the last. In Ireland its ancient inhabitants have left similar relics of their earthen defences, as in Great Britain the Romans have left of theirs; but the further consideration of the value of earthen works, when adopted in the defence of extensive fortresses, will be resumed in a future passage, and they will be considered here only in connection with the arrangements adopted by an army in the field for its own immediate security.

The art of constructing all kinds of temporary works in the field for this purpose is usually called field fortification, a name here replaced by that of parapet fortification. An army intrenched, or fortified, in the field, produces, in many respects, the same effect as a fortress; for it covers a country, supplies the want of numbers, stops the advance of a superior enemy, or, if he chooses to risk a battle, obliges him to engage at a disadvantage. "In a war of march and manœuvre," says Napoleon, "if you would avoid a battle with a superior army, it is necessary to intrench every night, and to occupy a good defensive position. Those natural positions which are ordinarily met with are not sufficient to protect an army against superior numbers without recourse to art. Those who proscribe lines of circumvallation, and all the assistance which the science of the engineer can afford, deprive themselves gratuitously of an auxiliary which is never injurious, almost always useful, and often indispensable. It must be admitted at the same time that the principles of field fortification require improvement. This important branch of the art of war has made no progress since the times of the ancients. It is even inferior to what it was two thousand years ago. Engineer officers should be encouraged in bringing this art to perfection, and in placing it on a level with the rest."[1]

Whenever Napoleon had time and occasion for strengthening his position by field-works, he acted upon the principles recommended in the above extract, as almost all his predecessors had done. In the wars which followed the revolution of 1688, in those of Queen Anne's reign, and during the Seven Years' War, we find the commanders of each period, William III., the Duke of Marlborough, Marshal Villars, Marshal Saxe, Frederick II., and Marshal Daun, practically exemplifying their conviction of the great utility of field-works. A few redoubts saved Peter the Great at Pultowa, and enabled him to gain a decisive victory over his formidable antagonist; and at Borodino, some slight open field-works, thrown up by the Russians, caused the French great loss, and rendered too costly to be of almost any avail the victory which, by incredible efforts of gallantry, they gained. It has been argued by some, against intrenchments and field-works, that they have oftener been carried than successfully defended, and that hence incommensurate importance has been attached to them. But it should be remembered, on the other hand, that victory in such circumstances has generally been purchased at an expense which rendered it in effect equivalent to defeat; and that a practice which the greatest commanders of ancient and modern times have approved and followed cannot be one of doubtful utility. At Austerlitz, where the contending armies were nearly equal, Napoleon was preparing to superintend the construction of intrenchments when he found himself called upon to receive battle; and in Portugal, the Duke of Wellington showed to what importance the art of the engineer might be turned for influencing, not merely the fortune of a campaign, but the fate of a cause. The lines of Torres Vedras, which formed the *ne plus ultra* of the powerful French army under Massena, and from which the tide of war was rolled back broken into Spain, were perhaps the most remarkable works of the kind ever constructed.

"Lisbon," says Sir John Jones, "being situated at the extremity of a peninsula formed by the sea and the Tagus, it is plain that if an army be so posted as to extend across the peninsula, no enemy can penetrate into the city without a direct attack on the army so formed. It was on this principle that the lines covering Lisbon were planned by Lord Wellington. Nature drew the rude outline of a strong defensive position, and art rendered it perfect. A tract of country thirty miles, extending from the mouth of the Zizandra on the ocean, to Alhandra on the Tagus, was modelled into a field of battle; mountains were scarped perpendicularly, rivers dammed, and inundations formed; all roads favourable to the enemy were destroyed, and others made to facilitate the communications of the defenders; formidable works were erected to strengthen and support the weak parts, whilst numerous cannon, placed on inaccessible points, commanded the different approaches to them, and gave an equality of defence to the whole position."[2] These lines were not continuous and connected works; they consisted of independent forts, redoubts, flêches, redans, batteries, &c., so placed as to command and enfilade every approach, and to support each other by a cross or a flanking fire. The first line occupied a front of twenty-nine miles between the sea and the Tagus; and by means of telegraphs intelligence could be conveyed from one extremity to the other in a few minutes; whilst the troops were disposed in masses in the rear of the works ready to move upon any point that might be attacked, by interior communications shorter than any by which the enemy could advance. "The aim and scope of these works," says Colonel Napier, "was to bar the passes, and to strengthen the fighting positions between them, without impeding the movements of the army. These objects were attained; and it is certain that the loss of the first line would not have been injurious, save in reputation, because the retreat was secure upon the second and stronger line, and the guns of the first were all of inferior calibre, mounted on common truck carriages, and consequently immoveable and useless to the enemy."[3] Both lines occupied a front of fifty miles, on which there were erected one hundred and fifty forts, mounting in all about six hundred pieces of artillery.

Before this formidable position, defended by a double line of works, and by an army massed and ready to move upon any point by interior communications, the French remained five months, wasting their numbers and resources; until at length, finding it utterly impracticable to force any part of even the exterior line, they were obliged to retire from Portugal, closely followed and harassed by the army which they had previously driven out of Spain. Yet though the lines of Torres Vedras were thus perfect in themselves, and though one of the ablest of the French generals and a veteran French army were foiled before them, it is not meant to refer to this system of separate field-works as a model to be followed on all occasions; for whilst the old method of covering a considerable front by a continued line of regular bastions and curtains has been universally condemned by modern engineers, it is nevertheless certain that there are situations where a partial application of continued lines may be most judiciously made. In fact, it is not by any fixed rule, but from the nature of the ground and of the position to be defended, that the species of works calculated to be most useful should, in every case, be determined.

At this point it is necessary to remember, that in any protracted defence, or, indeed, in any efficient defence, artillery must be combined with musketry; and hence that in the arrangement of lines provision must be made for the

[1] *Military Maxims of Napoleon.*

[2] *War in Spain*, p. 124. The French army which invaded Portugal under Massena consisted of three corps, under Marshals Ney and Junot and General Regnier, amounting in all to 66,000 infantry and 6000 cavalry, besides a strong body of the imperial guard, which crossed the Pyrenees after the invading force had commenced its march from the neighbourhood of Salamanca. The force collected to oppose this threatened invasion did not exceed 48,000 infantry and 3000 cavalry, of which about a half was composed of Portuguese levies, yet untried in any general action, and of which a very unfavourable opinion still continued to be entertained. In point of numbers, and still more in the composition of their army, therefore, the French had a decided superiority; but all their advantages were neutralized by the defensive position of Torres Vedras.

Artillery in defence.

use of cannon. When it is possible so to place guns that they may bear on definite lines or points, such as a natural ravine, an artificial road or other communication, a line of abattis or other obstacle, the ditch, the scarp, the glacis of some portion of the works which must be passed in advancing to the attack, or the point in front of a salient, it is desirable that they should be preserved in that position, ready to act at the right moment; and hence it is that they should not fire *over* but *through* the parapet, and the opening made in the parapet for this purpose is called an "embrasure." It is more usual to make these embrasures in field-works shortly before they are required to be used, so that the parapet may be made quite solid and firm in the first instance, and without the trouble which attention to the preservation of the opening would necessarily occasion in construction. In order to obtain command over a glacis constructed in reference to the exterior slope of the parapet, and yet to insure cover, the parapet must be raised so as to cover the men serving the gun placed on the usual barbette terreplein—(see fig. 22)—which would other-

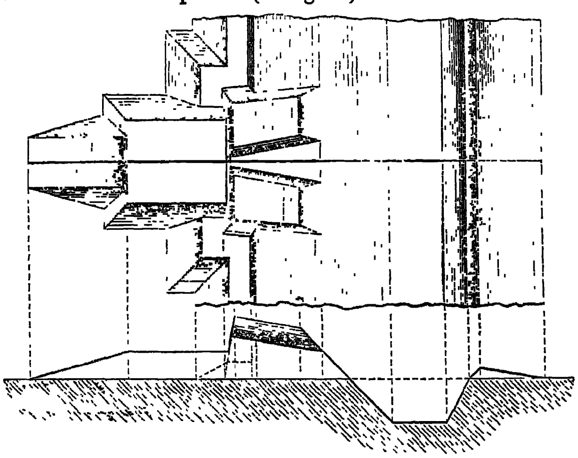

Fig. 22.

wise fire over the ordinary parapet, and not, as here represented, through an embrasure. The section shows by dotted lines the difference of level between the terreplein of the gun and the plane of the banquette of the ordinary parapet. The dimensions of the embrasure are determined on simple principles—the interior opening or neck is made only 20 inches wide to avoid unnecessary exposure of the men, and the exterior opening is made half the thickness of the parapet, measured along the ridge line of the exterior slope; (see fig. 23). When the guns are intended to flank the ditches, or to fire along a ravine, or the crest of a natural scarp, which fulfils the function, as an obstacle, of the ditch, the embrasures are cut in the ordinary parapet, and the guns stand on the natural terreplein of the work, as stated above.

The portion of parapet left below the embrasure is called genonillère, from genon, the knee; and for field-guns should be $3\frac{1}{2}$ feet high; the portion between two embrasures is called merlin, from the Italian *merlone*, a battlement; the bottom of the embrasure is called its sole; and in the same manner as has been suggested in respect to the superior slope of the parapet, it should be horizontal for the first four feet from the neck or interior opening, and then slope downwards as much as may be necessary to attain the amount of depression required in firing. The direction of the embrasure depends on the intended direction of the line of fire, and is either perpendicular to the crest as at *a'b*, or oblique as at *mn* (fig. 23). In the latter case, should the obliquity be very great, or exceeding 70°, the crest of the parapet must be made re-entering, as at *oi*, so as to strengthen it near the neck, and to enable the gun carriage to be brought up square to the parapet; *o* P should be at least 8 feet; the sides of the embrasure are called cheeks, and should be rivetted either with planks, with sods, with fascines, or with gabions (hollow cylinders made of wicker

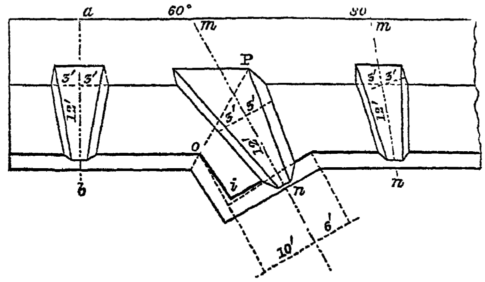

Fig. 23.

work, and filled with earth). In fig. 24, on the left, at B, a direct embrasure is seen cut straight through the parapet: and on the right at A, an oblique one, both being intended to enfilade the ditches opposite them; and it will be observed that, from the obliquity of the right-hand embrasures, the interior of the work becomes so much exposed, that a traverse, T, behind the embrasure, becomes necessary. Barbettes are also shown in this figure—one at the salient at D for four guns, and another at C, perpendicular to the

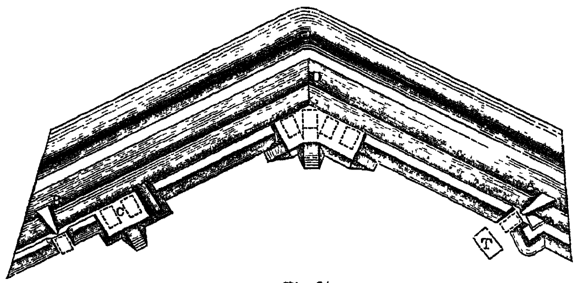

Fig. 24.

face or branch, for two. The terreplein of the barbette should be from 3 to $3\frac{1}{2}$ feet below the crest of the parapet; its height from front to rear from 18 to 20; and its breadth, for a single gun, from 15 to 18, according as it may be necessary to fire more or less obliquely; and a breadth of 12 to 15 feet should be added for every additional gun. To add to the lateral sweep or range of the gun, without diminishing the banquette, or, in other words, the musketry fire, the barbette may be made wider in the rear than in front. In proportion to its magnitude should be the number of "*ramps*," or slopes of approach; as, for example, at C only one, at D three. The ramps should be from 8 to 9 feet wide, and their slope should have a base equal to 4 times the height of the barbette. The lateral slopes of the barbette and of its ramps should be revêted whenever it is possible to obtain sods, fascines, or hurdles, in order to economize space in the work, as the base of the slope may be then reduced to $\frac{1}{4}$ or $\frac{1}{6}$ the height; more generally they are left unrevêted, with slopes of $\frac{1}{6}$. The terreplein of the barbette may require, as at C, to be covered in flank by a traverse. The mode of constructing a barbette in a salient is exhibited in fig. 25 *a*.

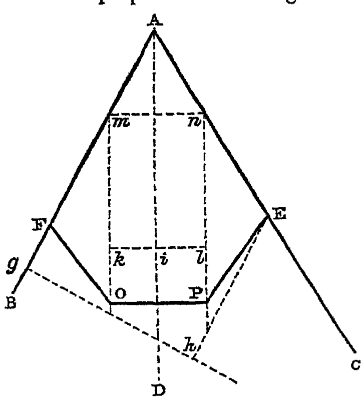

Fig. 25 *a*.

At any point *g* of the face AB raise a perpendicular *gh*, either 18 or 20 feet in length, to include the amount of re-

coil; at the point h thus determined raise a perpendicular to gh and prolong it to its intersection with the other face AC at E, then setting off AF on the other face equal to AE. On the capital AD, set off a double perpendicular at any point i, prolonging it both ways, and making ik and il each at least equal to $4\frac{1}{2}$ feet to represent the half breadth of the platform on which the gun-carriage is intended to stand and move; through the points k and l draw parallels to the capital, cutting the faces on the points m and n; join m, n, and parallel to the line mn draw the line OP at 18 or 20 feet distant from it, when m n P O, form the platform. Join FO and EP, and AEPOF will represent the contour or trace of the barbette. The manner in which the crest of the parapet is formed above the salient A, and the mode in which the firing may be effected in directions perpendicular to the faces, as well as in the direction of the capital, is shown in fig. 25 *b*.

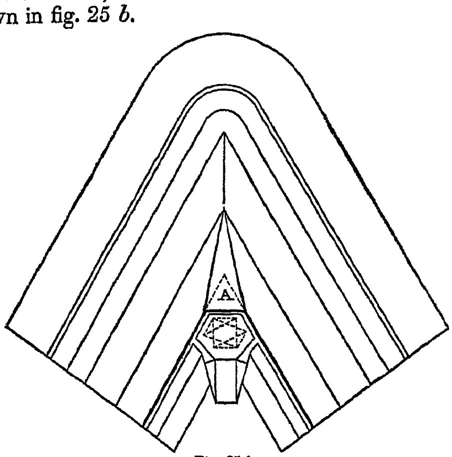

Fig. 25 *b*.

In the case of a partly sunken parapet, in which the portion above the banquette is raised above the plane of site, and the portion below the banquette excavated as in fig. 26, the barbette constructed in the hollow portion will enable the gun to fire over the parapet; and it should be protected by forming a bonnetted embrasure, which may be sometimes made large enough, as here represented, to hold two guns. It need scarcely be added that an engineer ought to be ready in adapting any of the expedients here briefly noticed to the circumstances of any particular case,

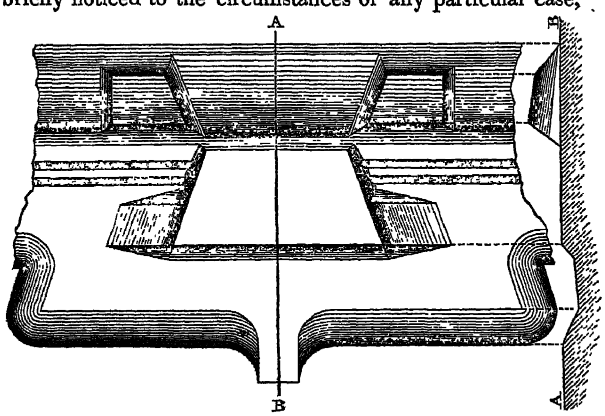

Fig. 26.

and that a mind stored with resources against any possible casualty is one of the highest endowments of a really good officer. It must be obvious indeed that even a limited knowledge of the art of war opens a wide field for the exercise of the talents and resources of engineers in field fortification; but the possession of a military coup-d'œil, or of that intuitive judgment which comprehends at a glance the true bearing or character of objects as well as events, is necessary to enable them to convert theoretical stores of information to the best practical uses. In passing through a country, it requires an experienced eye to seize quickly on whatever it presents calculated to prove advantageous or disadvantageous to an army destined to attack or defend it; to appreciate the value of villages, stone-inclosures, and broken ground; to know where to dam up rivers, to scarp heights, to form abattis, trous-de-loup, and other obstacles; to select the best situations for field-forts and redoubts, and the best sites for batteries; and to arrange all the defensive means employed, with reference to the number of troops destined to act upon the different parts of the line, so that the movements of the defenders may not be obstructed or retarded, and the communications throughout may be short and easy. The variety of ground, however, upon which military operations are for the most part carried on, precludes the possibility of laying down fixed rules in regard to this subject; the accidents of ground, and the peculiar circumstances of each individual case, must, as already observed, determine the extent and description of the works to be constructed, as well as the obstacles most proper to be formed for retarding, if not obstructing, the advance of an enemy.[1]

At the same time, though the observance of fixed rules be impracticable, general principles are of universal application; and certain maxims founded upon them hold equally good in regard to the construction of field-works as in that of the more complicated works of a fortress. These are, *first*, that the works to be flanked must never be beyond the range of the projectiles used in the works flanking them, or in other words the length of the lines of defence never exceed the effective range of musketry; *secondly*, that the angles of defence should be about right angles; *thirdly*, that the salient angles of all works should be as obtuse as possible; *fourthly*, that the ditches should be as efficiently flanked as is possible; *fifthly*, that the relief of the flanking works must be determined by the length of the lines of defence; and, *sixthly*, that in the construction of field-works, reference should not only be had to the direct and immediate obstacles which the work itself is calculated to present to the enemy, and the positive effect of its fire on the approaches to it, but the relative value of the work should likewise be considered with respect to the support it can receive from or give to other works. These principles or maxims are of invariable application.

Field-works are either open at the gorge as in fig. 1, 2, 3, 4, Pl. CCLIX, or inclosed all round as in fig. 5, 6, 7; namely—

Redans, or simple heads	fig. 1.
Double redans, or queues d'hironde	fig. 2.
Tenailled heads	fig. 3.
Bastioned heads	fig. 4.
Redoubts	fig. 5.
Star-forts	fig. 6.
Bastioned forts	fig. 7.
Lines à crémaillières	fig. 8.
Lines of redans	fig. 9.
Lines of tenailles	fig. 10.
Lines of bastions	fig. 11.
Lines of demi-bastions	fig. 12.
Lines broken or with intervals	fig. 14.

The first class are of the simplest kind of field-works, and serve as a mere cover in front of avenues, bridges, (see fig. 13), causeways, and the like; but being quite open at the gorge, they are only suited for defence when their extremities rest on rivers, or obstacles which prevent their being turned, or when within the full sweeping fire of works

[1] Shaw's *Course of Field Fortification*, p. 9, *et seqq*. Much assistance has been derived from this useful work in the compilation of this article, as well as from the admirable Treatise on Field Fortification by Fischmeister, translated by Rieffel into French, the figures of

in their rear. To increase the strength of a *redan*, its faces are sometimes broken into a kind of flank, as in fig. 1, Pl. CCLIX. In the *double redan*, or *queue d'hironde*, fig. 2, the re-entering faces defend each other; the *tenailled heads* are used in situations which require a greater extent of front; and the *bastioned heads* are also employed in similar circumstances. See fig. 3 and 4.

Redoubts are works closed on all sides; they are constructed of a square or polygonal figure, but most commonly square, as, when of this form, each front can furnish a strong perpendicular fire. Provision should be made for defending the ground before the angles, which, however, are sometimes rounded or cut *en crémaillière*, so that a fire may be delivered from them. See fig. 5.

Star-forts were proposed in order to remedy the defects of redoubts having the ground before them undefended by a flanking fire, so that a cross fire might be delivered from the adjacent sides. But according to Jomini, "star-forts are the very worst description of fortification; they cannot have flanks, and the re-entering angles take so much from the interior space that it is impossible to place troops and artillery in them sufficient for their defence:" an opinion confirmed by the practice of Sir Richard Fletcher and Sir John Jones in the construction of the lines of Torres Vedras, where the trace of the redoubts was made subservient to the conformation of the ground, to the object in view, and to the protecting them as much as possible from the fire of the enemy's position.

In *bastioned forts*, fig. 7, the flanking defence obtained for the ditch is nearly perfect. As bastioned forts are only constructed in cases of great importance, no labour or expense should be spared in the formation of such works.

Forts with demi-bastions, fig. 12, are objectionable, as the ditches are only defended by an oblique fire of their faces. The parapets of all these works should be of sufficient thickness to resist the fire of the heaviest guns that can be brought against them. In some cases, however, the parapets need only be strong enough to resist the fire of light field-guns, whilst in others it will be sufficient if they serve as a cover to the men within them against musketry. The latter kind is generally that which is thrown up in an evening after taking up a position, and which, if the army does not move next day, it may be considered as necessary to strengthen in some parts, according to circumstances.

Continued lines, or connected works, are resorted to in order to inclose the front, or to connect important works or forts. The most simple tracing is that of redans joined together by curtains (fig. 9); but as the ditches of these curtains can only be defended by an oblique fire from the faces of the redans, this defect may be remedied by breaking the curtains so as to form nearly right angles with the faces of the redans, in which case they are called *lines of tenailles*.

Lines en crémaillière have long faces, with flanks perpendicular to these, in order to defend their ditches. When the faces can be directed towards ground upon which it is impracticable to establish enfilading batteries, the construction is considered as good.

Bastioned lines form the strongest trace which can be given to continued lines, when the ground will admit of its adoption. A perfectly regular trace is only suited for level ground. The ditches in field-works are often sloped *en rampe* towards the adjoining flanks, in order that the *deblai*, or quantity of earth excavated, may not exceed the *remblai*, or quantity contained in the mass of the rampart or parapet, a circumstance which often occurs in field-works, where there is seldom any rampart, and only cover sufficient for the defenders.

Lines with intervals. Fig. 14 shows the general trace of lines of this kind. The salient works should never be beyond the range of musketry from the re-entering works, and the angles of defence between the two lines should be as near as possible to right angles.

Têtes-de-pont, or *bridge-heads*, are works generally open at the gorge, and whose flanks rest upon a river, in order to cover one or more bridges. The best situation for these works is the re-entering sinuosity of a river. As tetes-de-pont, fig. 13, are usually constructed for the purpose of enabling a retiring army to cross a river in order, and to check an enemy pressing upon it, the tracing and profile should be such as to secure a double advantage to the greatest extent possible. In Sir Howard Douglas's able work on the Construction of Military Bridges will be found much valuable scientific information upon this important subject.

The obstacles which are usually added to field-works, in order to render the approaches more difficult to the enemy, such as *palisades, barriers, abbatis, trous-de-loup, chevaux-de-frise, harrows*, and *crows'-feet*, have been already noticed.

For *the defence of open towns and villages*, the following methods, recommended by the French minister of war in 1814, are considered as the best that have yet been suggested: "To admit of a town being advantageously intrenched, it is necessary that it should not be commanded within any short distance, that the houses should not be of a construction easily set on fire, and that its extent should not be out of proportion to the means and time at the disposal of the defenders. The first thing to be done is to clear the approaches to the town, by levelling houses, hedges, shrubberies, and whatever may favour the assailants. Wood ought to be cut two feet from the ground, that it may serve to impede the advance of the enemy without masking the fire of the defenders. The next object is to form or complete the inclosure round the town. For this purpose advantage is taken of buildings, walls, and fences applicable to the defence. The openings which remain must be closed by palisades, stockades, or ditches strengthened by abattis. All streets leading out of town must be barricaded. The barricades must be sufficient to resist field artillery, and high enough not to be easily got over; and they ought to be flanked by loopholing the neighbouring houses. When pressed for time, carts filled with dung and the wheels taken off, sand-bags, bales of wool or cotton, and furniture taken from the neighbouring houses, all form good barricades. If there should be any old castle, church, or large substantial building, it should be converted into a keep, by blocking up useless entrances, loopholing walls, and surrounding them by a ditch or abattis. If a town is situated near a stream or river, by which part of it may be covered by inundations, this should never be neglected."

Villages are intrenched on similar principles, and being generally surrounded by gardens with live hedges, the latter may be made use of in forming the lines of defence. If there should only be sufficient troops to defend part of a village or town, a part only should be intrenched and separated from the rest by means of carts and barricades. If there are very few houses, it may be necessary to confine the defence to the church or churchyard, which may in all cases serve as a sort of keep.

The destruction of bridges. Nothing is of greater consequence to a retiring army than to be able to destroy the bridges in its rear, in order to retard the advance of the enemy. Its safety, nay even its existence, may depend upon the success with which this operation is performed. In order to destroy a stone-bridge, a trench in the form of a cross is made in the crown of the arch, the branches of which are about ten feet in length, and sunk to the top of the arch-stones. One hundred and sixty pounds of powder are placed in each cut or trench for an arch three feet thick, strong planks are then laid over the powder, and the whole being well covered with rubbish, the fire is communicated by means of a saucisson or long powder-hose. Stone bridges are also destroyed by simply cutting a trench about eigh-

teen inches deep across the crown of the arch, and placing in it 345 pounds of powder covered in the manner just described. This quantity has been found sufficient to destroy semicircular arches of twenty-five feet in span, and three feet in thickness at the key. Wooden bridges may be destroyed in different ways; they may be pulled to pieces, burned, or blown up. When there is time to take them to pieces, they are unspiked, and the timbers so separated that they may be speedily removed. The best method of burning such bridges is to tar them, and to cover and surround them with fascines or tarred brushwood. When it is necessary to blow up wooden bridges, this may be effected by means of 220 pounds of powder suspended under the superstructure, and fired in the manner above described.

A *ford* is rendered impassable by throwing in large stones, by sinking boards with spikes standing upright in them, by scattering in it crows' feet, or by placing harrows taken from the neighbouring farms. A low rubble wall may be formed across, so as not to be perceptible above the water; strong stakes may be driven into the bottom, and trees fastened to them; waggons loaded with stones, and the wheels taken off, may in like manner be employed; not to mention a number of other things which may be easily found, and which will answer the purpose equally well. The rendering a ford impassable by such means is only second in importance to the destruction of a bridge, when the enemy whose progress it is desired to retard has either no pontoon-train at all, or has outstripped it by the rapidity of his advance. In this way, much valuable time may be gained on the one hand and lost on the other.

In order to bring a retiring army into the position when the business of intrenching itself would naturally begin, some portions of the subject of defence have been in part anticipated in the preceding passages, and the main line of argument will be now resumed.

The essential characteristic of all works formed of earth is, that the musketry fire, on which the defence must mainly depend, being discharged over the crest of the parapet, the line of fire will be nearly in the plane of the superior slope of the parapet, and perpendicular to the line of its crest; and hence opposite a salient angle, as in the redan, fig. 27, there

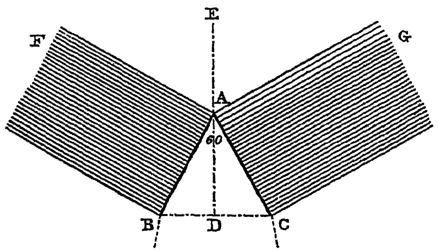

Fig. 27.

will be a large space of ground at A, in this case extending over $180° - 60° = 120°$, not defended by the fire of the work itself, and which is called a dead angle. Opposite re-entering angles, on the other hand, the defect is of a different kind, as the plane of the superior slope or plane of fire passing so high above the foot of the scarp, necessarily leaves it unseen and unprotected, notwithstanding that the two lines theoretically flank each other. The object, therefore, in arranging all field works for mutual defence should be so to regulate their reliefs that the line of defence should terminate at such a distance from the ground as to give an effective defence to the part of the work intended to be flanked. The redan may be considered the most simple form of *defensive* work, though a portion of straight parapet terminating by short returns at each flank, either in the form of epaulements or of regular parapets, may occasionally be combined with defensive works, and is an ordinary form of offensive work in batteries. The redan is open in the rear, and the line BDC is called the gorge—in this case a straight line—the two demi-gorges BD, CD coinciding in direction.

The lunette is a redan to which flanks or lateral wings have been added; and in form, therefore, it resembles a bastion. In Plate CCLIX., fig. 14, lunettes are shown so arranged that the faces of those in rear may flank the faces of those in front: but with respect to the distribution and arrangement of the works destined to form lines of intrenchment more will be said hereafter.

The tenaille is a work the reverse of a redan, as it consists of two lines forming a *re-entering* angle facing the exterior. It can, from its form, only be used in direct or approximate connection with other works which shall close up or cover the ends of its lines. Either alone or combined with redans it is very commonly used in continued lines of intrenchments. Plate CCLIX., fig. 9, represents a line of redans joined by straight lines, and fig. 10 a line of irregular tenailles, whilst the annexed cut, fig. 28, represents a normal

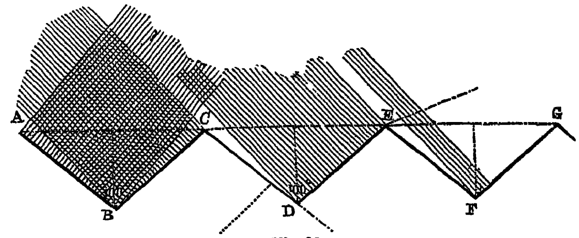

Fig. 28.

line of tenailles, of which the re-entering angles should not exceed 100°, and the sides are equal; and cut fig. 29, an

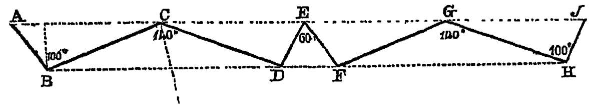

Fig. 29.

arrangement of tenailles, with irregular sides, by which a redan, as DEF, is interposed between every pair of tenailles. The line *en cremallière*, Plate CCLIX., fig. 8, is also derived from a combination of irregular tenailles, and is in many circumstances a very satisfactory arrangement. In selecting between these and other arrangements, including the bastion trace, Plate CCLIX., fig. 11, the engineer must be guided by his judgment on the nature of the ground and the special objects to be attained, and cannot therefore be bound by any rigid rules. A slight consideration, however, is sufficient to show that the combination of regular tenailles, in cut 28, is only applicable to ground in itself regular, an observation which applies to every strictly systematic arrangement in fortification. In almost every case the ground will be more or less irregular, and the works to defend it must be so also. When it is necessary to approach closely to a bank of a river or a ravine, the cremallière line, Pl. CCLIX., fig. 13, is the simplest and best, the short or flanking sides being so placed as to face the probable direction of approach, and next to that the combined redan and tenaille. Of open works, lunettes admit of the most scientific arrangement, as they can be so placed in lines with intervals as reciprocally to flank each other, and thus to form a line of defence very similar to a regular bastioned line. The employment, however, of works open at the gorge must be restricted to positions where the enemy can only approach in front, his advance in other directions having been rendered impossible either by other works, or by obstacles so arranged as to close that particular line of approach to an enemy. In every case it is desirable to take advantage of any peculiarities in the features of the country, and so to modify them as to produce such insurmountable obstacles as may relieve the minds of the defenders from apprehension of danger in that direction, and leave them at liberty to direct their attention more exclusively to the weaker points of their position; but in no case

should even the apparently inaccessible points be left unguarded, or rather unwatched, as an enterprising and skilful adversary will sometimes surmount difficulties which had appeared to others insurmountable. As such naturally defended points in a position can only be looked upon as exceptional advantages, it is evident that works left entirely open at their gorges would be liable to easy and frequent surprise, and therefore prove but imperfect instruments of defence. On this account it has been usual to prescribe as a rule that such works should only be left unclosed when within range of musketry fire from the defences behind them; but it is better to lay down as a fixed principle that in every case they should be secured at the gorge, as the power of driving an enemy out of the interior of such a work when taken is in reality of no value, as his object would not be to remain in its *interior*, but to turn its parapet to his own uses. The manner in which this is generally done is shown in fig. 30, which is a lunette se-

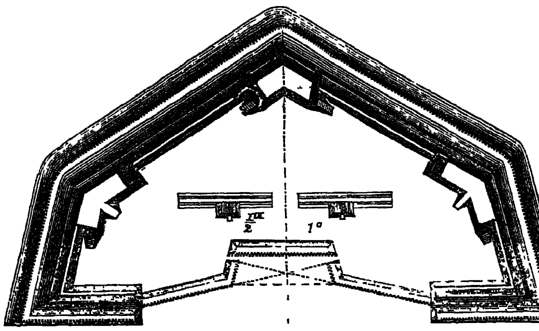

Fig. 30.

cured at its gorge by a loop-holed stockade, which is an obstacle effective against an enemy, and, at the same time, easy of destruction, should he succeed in temporarily obtaining possession of the works. Any of the obstacles previously described, such as abattis, &c., may be used for the same purpose, but they have the disadvantage of not covering the defenders of the work from the enemy's fire. An engineer in deciding between open works, such as those described, and close works, which will now be described, ought to take into consideration not only the circumstances of ground as regards the security of the work itself, but also the ease or difficulty with which support can at any moment be afforded to its garrison. Open works are not fitted for any position where they are likely to be left to their own resources, even for a moderately short time, as small bodies of men cannot be expected to stand firm against a vigorous attack from an overwhelming force, unless satisfied that support is at hand. Closed works, therefore, in which the parapet is continuous on all sides, can alone be relied upon under such circumstances; and even then the nature of the obstructions adopted in their construction should be such as to afford the garrison a reasonable confidence, that by a vigorous defence they may be able to hold the enemy at bay; for no general should expect to find in soldiers, as a body, that heroism which leads to self-sacrifice without hope. The easy capture of the redoubts at Balaclava, garrisoned by the Turks, is an illustration of this principle; for though it is possible that they might have been longer maintained by French or British soldiers, it would have been unreasonable to expect that their defenders should remain firm until overpowered and cut down by their assailants, which must have been the result had not a supporting force been at hand to relieve them. As general rules, therefore, it may be laid down, that in all detached works the mode and time of relief should be palpable to the garrison; the nature of the constructions such as to inspire confidence in the garrison as to its power of resistance for a reasonable time; and, above all, that the garrison of such works should be composed of the best, not of the worst soldiers.

Closed works may be either constructed without or with flanking defences; the first, which have only salient angles, being called redoubts, from the Italian *ridotto*, a place of rendezvous; the latter forts. Redoubts may be either formed as regular or irregular polygons of any number of sides, but the square redoubt is the most simple and the most generally used, see Pl. CCLIX., fig. 5. All such redoubts have the disadvantage of dead salient angles not having any flanking defence; and it is usual, therefore, to place the guns used in their defence, in the salients, so as to fire along the capitals or lines bisecting the salient angles, as well as the dead space in front of them. In like manner the sides should be made to front the probable line of approach, and as shown in one half of fig. 31, which represents a rectangular redoubt, the scarp is sometimes sloped gently down to the bottom of the ditch, and covered with abattis or other obstacles, which can then be seen and defended in front by direct fire. It is indeed impossible to repeat too often that the efficiency of defence in such works must mainly depend on the power of arresting the progress of the assailants just on those points where they will come under the fire of the defenders. The entrance to a redoubt should be made in the least exposed side, and be protected by a parapet traverse behind it, as in fig. 31, where an arrangement of palisades is shown by which the traverse may be connected with the other portions of the parapet, and the entrance be closed by gates or barriers as required. Other traverses may be also constructed in such works either for the purpose of defilade or for affording additional cover to the troops. They may be formed, when the work is sufficiently capacious, of long parallel epaulements, with a space between them, which may be even covered over or blinded when it is likely that

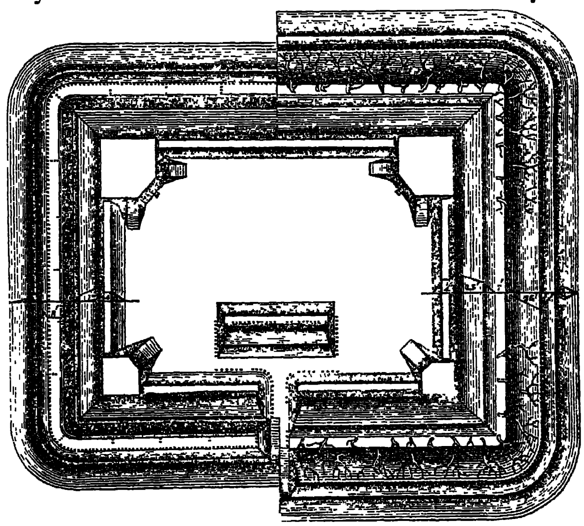

Fig. 31.

the work will be held for a considerable time, and in consequence that a more secure and comfortable lodging will be desirable for the garrison. Magazines for ammunition may be also constructed either against or in such traverses; and fig. 32 (see next page) represents, in plan and section, one which, formed behind a gabion traverse, is isolated from the parapet in front of it. This magazine is sunk partly in the ground, the sides being formed of planks and the roof of strong scantling, forming a ridge in the centre covered first with fascines and then with a coating of two or three feet of earth. Its dimensions are—length 8 feet, breadth 5, height 6.

Having thus generally sketched, as it were, this section of our subject, it is necessary to determine the least size which can be given to redoubts, so as to ensure a sufficient

Fortification.

interior space for the accommodation of the garrison required for the defence of the parapet, remembering that in works not provided with flanking defences the whole parapet, unless secured in part by some insurmountable *natural* obstacle, must be defended.

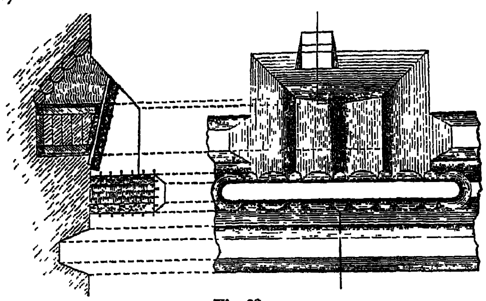

Fig. 32.

A general formula may be easily obtained for determining the least regular polygonal trace in the following manner:—Let x be the side in feet of any regular polygon, n the number of sides, A the interior surface reckoned from the foot of the banquette, y the number of men forming the garrison, f the number of linear feet allotted to each soldier, F the number of square feet occupied by each man in the interior,—then

$$fy = nx, \text{ and } Fy = A, \text{ or } y = \frac{nx}{f} = \frac{A}{F}; \text{ whence } \frac{n\,F\,x}{f} = A.$$

Again, let the perpendicular Cd, from the centre of the polygon (fig. 33) to its side AB, be p; the distance db from the side AB to the boundary line of the available interior space mn be d; then $Cb = p - d$; and as $Cd : AB :: Cb : mn$, $p : x :: p - d : mn$, or $mn = \frac{px - dx}{p} = x - \frac{dx}{p}$. Now, the value

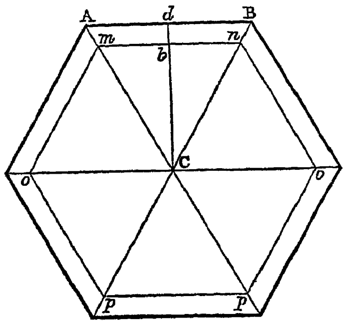

Fig. 33.

of p expressed as a function of x and of the angle of the centre ϕ, which is $= x\ \frac{1}{2}$ cot. $\frac{1}{2}\ \phi$, varies with the nature of the polygon; and replacing, therefore, the variable coefficient $\frac{1}{2}$ cot. $\frac{1}{2}\ \phi$ by β, $p = \beta x$, and mn, the side of the interior space $mnpo$, $= x - \frac{dx}{p} = x - \frac{dx}{\beta x} = x - \frac{d}{\beta}$, and $Cb = mn \times \frac{1}{2} \text{cot.} \frac{1}{2} \phi = \beta \left(x - \frac{d}{\beta}\right)$. The surface of the interior triangle $Cmn = \frac{1}{2}\, mn \times Cb$ is therefore $= \frac{1}{2}\, \beta \left(x - \frac{d}{\beta}\right)^2$, and $A = \frac{n\beta}{2}\left(x - \frac{d}{\beta}\right)^2$; whence $\frac{n\,F\,x}{f} = \frac{n\beta}{2}\left(x - \frac{d}{\beta}\right)^2$, and by reduction $x = \frac{1}{\beta}\left\{d + \frac{F}{f} + \sqrt{\frac{F}{f}\left(2d + \frac{F}{f}\right)}\right\}$. The variable $\beta = \frac{1}{2}$ cot. $\frac{1}{2}\ \phi$ is as follows:—

In the triangle,	0·288
„ square,	0·500
„ pentagon,	0·688
„ hexagon,	0·866

and taking the square under the following conditions:—$d = 12$ feet, $f = 3$, $F = 6 \times 3 = 18$, $x = 62{\cdot}81$ feet (21 yards), which may therefore be taken as the side of the smallest square redoubt to be defended by one rank only of soldiers, the garrison being 84 men with a single rank: and a reserve equal to $\frac{1}{3}$ of the garrison; $f = 2$, and $x = 76{\cdot}66$ feet, or nearly 26 yards, the garrison being 156 men. If there are to be two ranks, $f = \frac{3}{2}$ and $x = 89{\cdot}6 = 30$ yards nearly, the garrison being 240 men; and if two ranks, with a reserve equal to $\frac{1}{3}$ the whole garrison, $f = 1$ and $x = 115$ feet, or about 38 yards, the garrison being 456 men.

Fortification.

Triangular redoubts are rarely used, from their small interior space as compared with the length of their parapet; thus the smallest triangular redoubt intended to be defended by a garrison of two ranks should have a side (x) 54 yards in length, and a garrison of 324, the total length of parapet required to be constructed for this force being 162 yards; whereas a square redoubt of 38 yards' side will accommodate a garrison of 456 men, admitting of a two-rank defence, and of a reserve of $\frac{1}{3}$ the whole garrison, with a total length of parapet of only 152 yards; and this objection of limited space is further strengthened by the great amount of dead-angle space before the salients. Keeping these numbers, as regards square redoubts, in recollection, the engineer will be able at once to determine his arrangement of the proposed garrison, and yet to limit himself to the least amount of work in parapet. If, however, he has to provide for guns, for traverses, or for other constructions, he must increase the side of his square, remembering that in the case of the square of 38 yards' side the augmentation of 1 yard per side will require only the addition of 12 men to the garrison, making it 468, and the additional interior space for their accommodation of 216 square feet; whereas there will be a gain of space of 549 square feet, leaving an excess towards the objects stated of 333 square feet; and if the side were increased to 45 yards, and the garrison to 540 men, there would be a surplus interior space of 2709 square feet, being sufficient for barbettes for three guns and for one howitzer, and for a traverse; and this size may therefore be assumed as the best for a normal redoubt. It is generally stated that, passing this limit, some of the forms of forts should be adopted, as diminishing to a certain degree the defects of redoubts, by introducing more or less perfect flanking defence; but in practice it will be often preferable to use a larger redoubt, as the flanking defence obtained on very short lines must be extremely imperfect, and therefore more liable to deceive by false security than to benefit. In Pl. CCLIX., fig. 5, one of the angles is shown with an indented parapet as a means of correcting the defect of a dead salient; but this is difficult of construction, and it will generally be preferable either to cut it simply off as in another angle of the figure, or to round it as in a third, or to occupy it by a gun *en barbette*, as in the fourth. Of forts, fig. 6 exhibits a star fort of eight points formed upon a square, which is far preferable to one of six points formed upon a triangle, as giving comparatively more available space. The defect, however, in this trace is, that though the intermediate angle F is sufficiently open—as it exceeds 60°,—the angles A and B are less than 60°. Down to the lowest limit of such forts, in which AB of fig. 6 is taken at 60 yards, and the sides AE, EF, EB at 20 yards, there is still sufficient space to accommodate the necessary garrison, which should be in that case about 900 men. It is useless to describe those forms of star forts, which would not accommodate the required garrisons; but that represented in fig. 34 (next page) is well fitted for a large garrison. A simple construction on a pentagon is:—Bisect AB in C; make the perpendicular $CP = \frac{1}{4}$ AB; join AP and BP; make Bd and Ad each $\frac{5}{12}$ of AB, and joins dc, dc. In this case the angles at A and B will be 64°, and the short sides (with an exterior side of 120 yards) each 23 yards. From what has been already said in a preceding page, half-bastion forts,

CCLIX., fig. 12, will rarely be adopted; but when the extent of the proposed garrison is such as to require a large amount of accommodation, and there is time to undertake such works, the bastioned trace should be adopted, as it introduces a principle not observed in the preceding traces, namely, that of defending the whole by a part, the opposite flanks EG, FG of the two bastions GEAFG, GFBFG, defending the intervening curtain GG between them, as well as the faces AE, BF of the bastions—whilst the fire of one flank necessarily sees the scarp of the opposite one and defends it. The bastions are indeed, like their analogous lunettes, works in themselves; the curtain being only a connecting line, forming several bastions into one connected whole. Pl. CCLIX., fig. 7, is a square bastioned fort, but the pentagon is a better form, and should be adopted when practicable. It may be said that the bastioned form of field forts has been derived from the more massive structures adopted in the permanent defences of fortresses, whilst the other traces have naturally sprung out of the earliest and rudest works even of savage tribes, for they too had their redoubts, and have only been reduced to more definite rules by the progress of military science. The history, therefore, of the bastion trace, so interesting in itself, will be postponed to a future page. Little more then requires to be said on this section of the subject, further than to point out the great importance of field-works, in securing a base of operations for an advancing army. Pl. CCLIX., fig. 13, exhibits, for example, a bridge head consisting of a bastioned front, with either simple straight branches or branches provided with a short flank as shown in the figure (see also fig. 35 below). This is, as stated before, technically called a horn work; and if there had been two such fronts so placed as to throw a bastion in the centre, and connected as before with the river by straight branches, the work would have been called a crown work. Lunettes also may be used, and evan redans constructed, as fig. 1 of the plate (left side), for a similar purpose, where the object is simply first to secure the bridge from

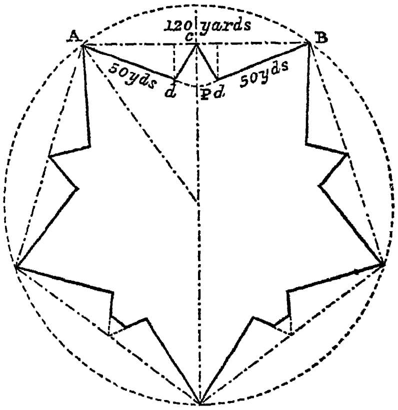

Fig. 34.

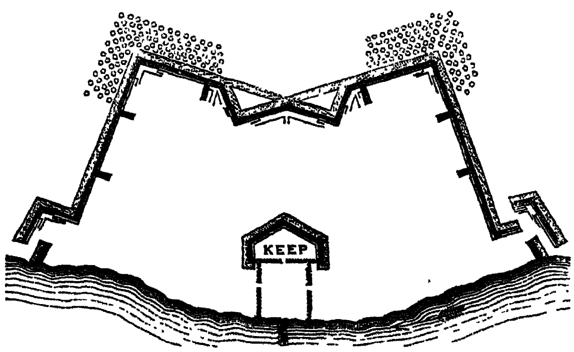

Fig. 35.

the enemy's attack and fire, and secondly to allow the defending army to manœuvre on the opposite side when desirable: but just in proportion to the numbers passed over the bridge, and to the extent of advance contemplated, will it be necessary to increase the importance of the works forming the bridge head, as it will be often necessary to form more than one bridge in connection with it. Nothing can be more fatal to a retreating army than to find itself driven back to a river, and to have no sufficient line of intrenchment to enable it to maintain its ground whilst its arrangements for passing the river are in progress. Fig. 35 exhibits one such arrangement in which the horn work front has been much enlarged, and a lunette as a keep introduced within it. The mode in which the troops can move out at the sides, under protection of covering and flanking parapets, is shown, as well as the barbettes for guns, which become necessary in works having so important an object. Fig. 36 represents a line of tenaille intrenchments in front

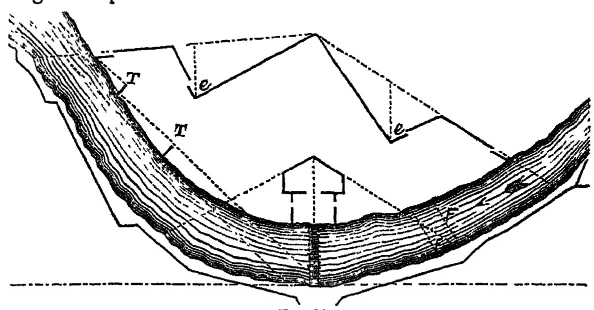

Fig. 36.

of the lunette, and a line of intrenchment is also shown on the near side of the river, from part of which the last terminal branches of the tenailles are flanked. In this figure T, T represent traverses, and F, F either chains or lines of pickets placed across the stream; the object of the first being to secure the bridge from the ricochet fire of the enemy, and of the second to secure it from destruction by burning or explosive bodies launched by the enemy in the stream, and allowed to float down. More extended intrenchments might be formed of lines of lunettes with intervening intrenchments; but it is unnecessary to pursue the subject in this suggestive manner further, as the engineer must necessarily adapt his works to the nature of the ground, and to the extent of the army for which he is required to prepare in this manner a defensive position, from which it may either advance or retire, without risk or confusion, as the necessities of war may require.

RAMPART OR TOWN FORTIFICATION.

Rampart fortification.

If, as has been stated, the simple lines or works of parapet fortification appear to have been adopted even by the rudest tribes of wandering savages, for their temporary defence or security, the more massive and artistic works of rampart defence would seem to imply a certain amount of civilization. As an art, indeed, fortification is very nearly as ancient as the existence of society. When men first assembled together for the purpose of mutual protection, and placed their habitations on the same spot, the law of necessity, springing in this case out of the principle of self-defence, rendered it indispensable for them to adopt some means for securing their families and their property against the sudden inroads of enemies. Hence, when Cain, the son of Adam, built a city, he surrounded it with a wall; and, in like manner, the Babylonians, when they built cities soon after the Deluge, encompassed them with similar defences. In the early ages, men considered themselves as sufficiently protected by a single wall, from behind which they could with safety discharge their darts, arrows, and other missiles, against an assailant. But when, in the progress of improvement, new and more powerful means of attack were discovered, it became necessary to increase, in a corresponding degree, the inert force of resistance; and

accordingly the feeble defensive structures of the primitive ages were in time succeeded by solid ramparts, flanked and commanded by elevated towers. In short, as the power of attacking fortresses or places of strength was augmented by successive devices and inventions, the means of resistance were proportionally increased, until the art of fortification arrived at a state of comparative perfection, in which it remained for many ages nearly stationary

The various improvements which were from time to time made in strengthening the walls, and adding to the defences of ancient cities, are recorded in history, and need not be detailed in this place. The first walls which we read of consisted of brick, the material employed by Cain for the protection of the city which he founded, and called by the name of his son Enoch. Amongst the ancient Greeks, brick and rubble stones intermixed were used for the same purpose, as we find from the description of the wall which connected Mount Hymettus with the city of Athens; but, in addition to such structures, should be noticed the works, surrounding several cities, of Cyclopean structure, built of huge stones, placed with their longer axis transversely to the line of wall, and arranged with great care and skill, though without mortar. The walls of Babylon and Nineveh indicate a prodigious advancement in the art of fortification, and are justly accounted amongst the wonders of the ancient world. Those of the former city, ascribed by some to Belus, and by others to Semiramis, were thirty-two feet in thickness, and one hundred feet in height, surmounted by towers at an average ten feet higher, and cemented by means of bitumen or asphaltum; they encompassed a vast area, and presented a solid defence, which no means of attack known in ancient times were sufficient to overcome or beat down. The walls of Jerusalem, though of smaller dimensions, appear to have been little inferior in strength and solidity to those of Babylon; for, in the siege of that capital by Vespasian, all the Roman battering-rams and other engines, though used with the utmost vigour, required a whole night to disengage four stones in the masonry of the tower of Antonia. But when fortification had arrived at the state in which we find it in the works of these and other cities, it remained stationary for ages, and perhaps even retrograded somewhat, until the discovery of gunpowder, the invention of artillery, and the application of both to military purposes, effected an entire revolution in the principles of attack and defence. Then the round and square towers, which had formed secure flanking defences against assailants armed only with arrows and with darts, afforded no protection against the projectiles discharged by cannon; and even those battlements which had defied the catapult and the battering-ram speedily yielded to the force with which they were now assailed, whilst their defenders were at the same time destroyed, or buried in their ruins.

It being thus found that the ancient system of fortification was of little or no avail against the new method of attack which had been discovered, and which came into general use towards the close of the fifteenth century, it became indispensably necessary to adopt another method of defence. The plan of fortifying with bastions is believed to have commenced with the Italians early in the fifteenth century; though Papacino D'Antoni, professor of artillery and engineering of Turin, states, in his *Architettura Militare* (1759), that several small bastions had been constructed in the preceding century, and that the ruin of a large bastion which had formed part of the fortifications of Turin, built for Duke Louis of Savoy, still existed in the royal gardens at that time. The bastions on the enceinte of Verona, built by the Italian engineer Micheli, in the year 1523, are generally supposed to be the oldest extant; and the next, probably, are those still to be seen in the citadel of Antwerp, and which were constructed for the Emperor Charles V. in the year 1545, by the Italian engineer Paciotto D'Urbino. These bastions are small, with narrow gorges and snort flanks and faces; and they are placed at a great distance from one another, it being the invariable practice, at the time when they were built, and for a considerable time afterwards, to attack the curtains, and not the faces, of the bastions.

Errard of Bois-le-duc, one of the principal officers of the engineer corps first organized by Sully, prime minister of Henri IV., and from which has sprung the French Corps du Genie, was the first in France who laid down rules respecting the best method of fortifying a place, so as to cover its flank. At the command of the minister, he wrote a book on the subject, which was published in 1594, and in which the details of his method are explained. As a writer on fortification, he was preceded in France by Beril de la Treille, who published his work on fortifying towns and castles in 1557. Errard fortified inwards; and in the square, pentagon, hexagon, heptagon, and octagon, he made the flank purpendicular to the face of the bastion; but in the enneagon, and in all polygons of a greater number of sides, he made it perpendicular to the curtain. In endeavouring to accomplish his object, however, he made the gorges too small, the embrasures too oblique, and left the ditch almost defenceless. This engineer constructed part of the enceinte of the citadel of Doutens, as well as the citadel of Amiens, and also some works at Montreuil and Calais.

The Chevalier Antoine de Ville, who succeeded Errard, published a treatise, dated 1629, in which he completed much that his predecessor had only sketched, and rectified various defects in the method of the latter. The Chevalier was employed under Louis XIII., and constructed new enceintes for Montreuil and Calais. His plan of fortifying has been denominated by some the French method, and by others the Compound System (*Système à trait composé*), because it united the Italian and Spanish methods, from the latter of which it differs only in having no second flanks and fichant lines of defence, and in not confining the flanked or salient angle of the bastion to ninety degrees. The leading maxims of the Chevalier de Ville were, to place the flanks perpendicularly to the curtain, to make them equal to the demigorges, or each equal to a sixth part of the side of the interior polygon, and, in the hexagon and all higher polygons, to confine the flanked angle to ninety degrees. But this plan is liable to nearly the same objections as that of Errard; for here, also, the embrasures are too oblique, especially in the polygons, and the ditch is necessarily but ill defended.

Sixteen years after the publication of De Ville's treatise appeared the work of the Comte de Pagan, which issued from the press in 1645, and contained the development of a system which, in a short time, entirely superseded those of his predecessors. In fact, it was the Comte de Pagan who first disengaged the science of fortification from a number of suppositions which custom had in some measure consecrated, and which, resting more on abstract mathematical reasoning than on practical observation and experience, had hitherto retarded the progress of the art. This engineer acquired great reputation during several sieges which he assisted in conducting under Louis XIII.; but having become blind at the age of thirty-eight, he was obliged to retire from the service, in which he had already obtained the rank of mareschal-de-camp, and he died six years after completing the treatise above-mentioned, in which he embodied a full exposition of his system. The Comte de Pagan made the flank perpendicular to the line of defence, in order as much as possible to cover the face of the opposite bastion; and he also pointed out a method of building casemates in a manner peculiar to himself. Vauban borrowed from the Comte de Pagan the length of his perpendicular, and Allain Manesson Mallet, whose construction

still remains in favour with many, also proceeded upon the principles laid down by this scientific soldier.[1]

The Mareschal de Vauban was born in 1633; and in 1655, at the time of the Comte de Pagan's death, he had already acquired reputation at several sieges. Vauban followed up the principles suggested by Pagan, and employed them extensively in practice, with consummate skill and judgment. He constructed thirty-three new fortresses, repaired and improved one hundred; and having conducted about fifty sieges, he left his extensive works, and a treatise *De l'Attaque et de la Defense des Places*, published in 1737, to speak for themselves. From the different constructions observable in these works have been compiled the systems which, in the military schools, are denominated Vauban's first, second, and third systems of fortification, and which the reader will find developed in the sequel. Had the genius of Vauban been applied to the discovery of a method for securing a permanent superiority to the defence of fortified places, posterity would have been greatly indebted to him, and even humanity would have had cause to rejoice in such a triumph of military art. But, being engaged in the service of the most ambitious monarch of modern times, Louis XIV., he applied his great talents to forward his master's views, and soon perfected that irresistible system of attack,[2] which has ever since been so successfully followed. Before his time the general superiority was on the side of the defence; but ever since, the case has been so completely reversed, that the success of an attack made with adequate means, and scientifically conducted, is a matter of ultimate certainty.

Nor should the protracted siege of Sebastopol be considered an exception to this rule, as the principal cause of its hitherto successful defence must be sought in its freedom from investment and the consequent incessant renewal of its garrison, thus withdrawing the siege operations from the influence of the sound maxims of Vauban.

Considering that at this time, when the public mind is generally impressed with a desire to have a more practical bearing given to general education, there still may be a tendency on the part of public authorities to retrograde as regards military education, and to *substitute* for the mathematical sciences the classical languages, it is well to notice briefly the characters of Errard, of Pagan, and of Vauban. Errard was one of the most distinguished members of a corps formed out of the best instructed and most experienced military men he could find, by the great Sully, who was grand-master or master-general of the artillery in the reign of Henri IV. of France. This corps, called by Sully "Engineers in ordinary to the King," has now become the Corps du Genie, and has to this day maintained its high character as a body of scientific men. Compte Pagan had from his earliest years devoted himself to the study of mathematics and fortification. At the age of thirty-eight he was afflicted by blindness, but before that time he had served with distinction at twenty-five sieges, and acquired the rank (then second only to that of marshal of France) of field marshal. Besides his celebrated work on fortification, he published several others on Astronomy. Vauban was no ordinary man in any sense. As the inventor of parallels in sieges, and of the ricochet fire, he stands on the first rank of military engineers for invention, and when it is considered that he conducted fifty-three sieges and shared in 140 battles and skirmishes, he must be considered an equally experienced one. At fifty-five years of age he attained the highest honour of the French army, being created marshal of France; yet amidst this stirring and successful military life he never failed to turn to account the geometrical knowledge for which he was distinguished when a youth, and which had obtained for him the early notice of the Prince de Condé. His mind was, therefore, never idle, but constantly directed to projects of public utility, whether military or civil, and he left behind him records of such labours in twelve folio manuscript volumes, entitled *Mes Oisivetés*, at once a monument of his own ability and industry, and a beacon to guide subsequent engineers to that course of useful as well as intellectual activity which it ought to be their pride to follow.

M. Minno Baron de Coehorn, first a general of artillery, then a lieutenant-general of infantry, and ultimately director-general of all the fortified places belonging to the United Provinces of Holland, was the contemporary and rival of Vauban. This able engineer, convinced that, however expensively the rampart of a town may be constructed, it cannot long resist the shock of heavy ordnance, invented three different systems for throwing such obstacles in the way of a besieging force, that, although the place be not thereby rendered impregnable, it can only be approached with great difficulty and hazard. But these methods, without much modification, are only applicable to low and swampy situations, such as are to be found in Holland, and are therefore not available where the localities are of a different or opposite description. At the same time, Bergen-op-Zoom, Manheim, and other places fortified by this engineer, particularly the two former, have very great merit, inasmuch as it is impossible for a besieger to penetrate into any of the works, without being exposed, on all sides, to the fire of the besieged, who are under cover; and from artillery and musketry it is scarcely possible for an assailant to shelter himself. In fact, Coehorn was a great master, and combined, as will be observed hereafter, many of the means of defence springing from another source with the bastioned trace. He published his first work on fortification before he had acquired much practical experience; and in fortifying Bergen-op-Zoom, which is allowed to be his masterpiece, did not reproduce, except as fragments, any of his published systems.

Since Vauban's time several improvements have been suggested, particularly by Cormontaigne, who entered the corps of French engineers in 1716, nine years after Vauban's death, and died a mareschal-de-camp in 1750. Some account of the system of Cormontaigne will be found in a subsequent part of this article. The three methods delivered by Belidor are all applicable to an octagon of two hundred toises. Scheiter distinguished his systems into great, mean, and little, in imitation of Pagan, requiring the exterior sides of the polygon to be, respectively, two hundred, a hundred and eighty, and a hundred and sixty toises: he adopted from Castriotto detached bastions, and made use of a continuous fausse-braye. Fritach, a Pole, proposed two methods, which he exemplified on different polygons. Dogen, a Dutchman, published a large volume on fortification, in which, after enumerating various modes employed by different writers for determining the salient angle, he selected three as the most approved, and proposed as many methods of construction, one of which is borrowed from Fritach, the Pole. Pietro Sardi, an Italian, suggested a peculiar method of construction on a hexagon. The Sieur de Fontaine found the flanked or salient angle of the bastion by adding fifteen degrees to half the angle of the figure, from the square up to the dodecagon, in which last it becomes ninety degrees, and at this he continued it in all the higher polygons. He also constructed outwards, and, in every regular figure, made the curtain equal to seventy-two

[1] Mallet constructs outwards, making in every figure or polygon the demigorge equal to a fifth part of the side of the interior polygon or figure, the capital of the bastion equal to a third part of the same side, the curtain equal to three-fifths or thrice the demigorge, and the angle of the flank equal to 98°. The faces of the bastions and the flanks are determined by the lines of defence, which are razant. From these data all the other lines and angles are easily found.

[2] See his work *De l'Attaque et de la Defense des Places*, passim.

toises, the face of the bastion to forty-eight, and the flank, which he placed perpendicularly to the curtain, to eighteen toises, or a fourth part of the curtain. Ozanam and Muller delivered each four methods of construction, the particulars of which will be found in their respective works. In 1751, Charles Bisset, who, as an engineer-extraordinary, served with the Duke of Cumberland in the Netherlands, and was present during the siege of Bergen-op-Zoom by the Mareschal Lowendahl, published a treatise on the theory and construction of fortification, in which there are many sensible and judicious remarks; and the same general description may be applied to an *Essai sur la Fortification, ou Examen des Causes de la grand supériorité de l'Attaque sur la Defense*, published anonymously in 1755. In a work entitled *Science de la Guerre*, which appeared at Turin eight years before the date last mentioned, a new method of construction is proposed, in which the principal objects to be attended to are, that there be mines under all the works, and that a regular communication be kept up with the chambers by means of subterraneous galleries, to be resorted to in proportion as the enemy approaches the body of the place. The third volume of the *Œuvres Militaires* contains some useful observations and maxims relative to irregular fortification; and in the Supplement to the *Rêveries* of Mareschal Saxe, by Baron d'Espagnac, the subject of fortification generally is amply discussed, and an accurate description given of the different means of attack and defence. Besides the writers above enumerated, may be mentioned the Chevalier St Julien, an able engineer, who published a method by which, he asserts, works may be constructed at a less expense, yet in such a manner as to render the defence or attack more formidable; Francisco Marchi, of Bologna, who, in 1599, furnished no less than a hundred and thirty-nine different methods of constructing fortifications, many of which are very valuable, and afforded useful hints to subsequent engineers, who have indeed greatly profited from his work; Bombelle, who established three kinds of fortification, called the grand royal (*grand royal*), the mean royal (*moyen royal*), and the little royal (*petit royal*); Blondel, who published a system divided into two principal heads, the great and the little, whose exterior sides are respectively two hundred and a hundred and seventy toises; Donato Rosetti, a canon of Livorno, who wrote on the method of constructing works in what he calls *fortification à rebours*, or fortification in reverse, so denominated because the re-entering angle of the counterscarp being opposite to the flanked angle, it will, according to him, be necessary to attack it from the reverse side of the other works; and Antonio de Herbart, major of artillery in the Duke of Wurtemburg's service, who published a treatise on fortifications with what he calls *angular polygons*. The treatise entitled *Nouvelle Manière de fortifier les Places, tirée des méthodes du Chevalier de Ville, du Comte de Pagan, et de M. Vauban, avec des Remarques sur l'ordre renforcé, sur les desseins du Capitaine Marchi, et sur ceux de M. Blondel*, which appeared in 1689, is full of strong reasoning, whence the author deduced a new system; but it contains little that is really original, though it gives numerous references to what had previously appeared, and disposes the different parts in a judicious manner. M. de Montalembert's system of casemated and reverse fire has been in part adopted in the splendid fortress of Alessandria in Italy, constructed under the directions of Napoleon.

Of the more recent treatises on fortification, by far the most elaborate and complete is that of M. de Bousmard, entitled *Essai Général de Fortification, d'Attaque et de Défense des Places, dans lequel ces deux Sciences sont expliquées et mises l'une par l'autre à la portée de tout le monde*; a work which enjoys a deservedly high reputation. It is remarkable for great accuracy and research, and may be considered as embodying in itself every thing that is valuable in connection with the subject of which it treats. M. de Bousmard's work, therefore, though intended to serve as an elementary treatise on fortification, is too expensive for the pecuniary means of a great number of inferior officers, whose instruction the author professes to have had chiefly in view: but to teachers of fortification it is altogether indispensable; and as long as the science and practice shall continue on their present footing, it will be deservedly considered as the most comprehensive and valuable work on the attack and defence, as well as the construction, of all kinds of fortification.

With regard to Carnot's *Traité de la Défense des Places Fortes*, it was written to serve a temporary purpose; and the exaggerated celebrity which it acquired on its first appearance has been succeeded by an equally unfounded neglect. The more prominent innovations recommended in this treatise were, first, an alteration, which, however, was not original, in the trace or outline of the polygon; secondly, the suppression of the exterior revêtement of the covered-way, known as the counterscarp; thirdly, the detachment of the scarp-wall from the rampart, and the construction of the latter without revêtement; fourthly, destructive personal conflict with the besiegers by means of frequent sorties; and, lastly, making vertical fire the basis rather than an accessory of the defence. With regard to the first of these proposals, all of which the reader will find very ably discussed in Jones's *Journals of Sieges in Spain and Portugal*,[1] we have only to remark, that by means of an increased expenditure for retrenchments and casemates, as recommended by Carnot, the strength of particular portions of the polygon may be increased; and that, if he has failed in tracing a perfect front, founded on the basis of Montalembert's system of casemated and reverse fire, he has at least rescued a valuable suggestion from unmerited neglect, and rendered an important service to science by directing the attention of military men to the means most likely to create a barrier against the growing powers of the attack.

The *Traité de Fortification Souterraine, suivi de quatre Mémoires sur les Mines*, by M. Mouzé, lieutenant colonel of engineers in the French service, was published at Paris in 1804, and is justly considered as the most complete work on the subject it treats of which has yet been given to the public. Subterranean fortification is a branch of the art which, until a very recent period, was wholly neglected in this country, and in which our engineers were far behind their brethren of the continent. We learn from Colonel Jones's work on the Peninsular Sieges, that the Duke of Wellington's army in Spain was unattended by a single regularly-trained sapper or miner until late in the year 1813; and many valuable lives were sacrificed, from the want of these valuable, or rather indispensable auxiliaries. In this respect things are now changed, and the engineer has the assistance of a body of men well instructed in the duties of the trench, the sap, and the mine; but it cannot yet be said that the corps of sappers and miners has been sufficiently augmented, whilst it may be feared that the growing idea that the ordinary navvies might with advantage replace them, may check the desire of increasing the body. In war, it must be remembered that discipline is as important as skill, and that the labourer who would have worked with the greatest effort under ordinary circumstances might be found very ineffective when forced to work on his knees in a sap, and when exposed to an enemy's fire obliged to remove calmly the man before him when killed, and then, with equal composure, to step into his place.

The preceding hasty and imperfect summary of the pro-

[1] Vol. ii., p. 131, *et seqq.*

gress and literature of fortification has been given principally in connection with the bastioned trace, as the one more generally used both in the French and English schools in teaching the principles of the science; and justly so, as, theoretically speaking, it exhibits the most perfect arrangement of flanking or reciprocal defence. It is, however, desirable, before going further, to recur back to the earlier epochs, and to investigate the manner in which the ancient arrangement of a wall, with its round or square towers, passed into the present systems of defence. The accompanying figure (No. 37), will explain the natural and pro-

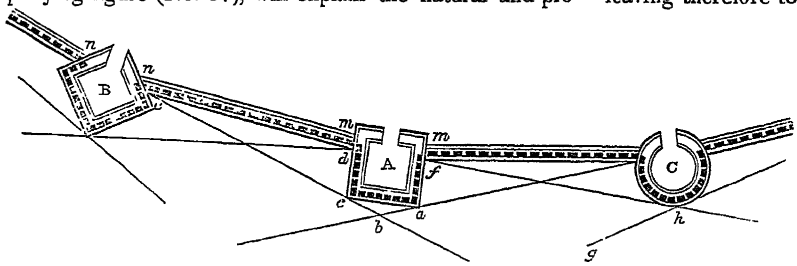

Fig. 37.

bable manner in which the old tower or rather tower-fort (*baluardo*) was changed into a pentagonal bastion. If, for example, lines of defence be drawn from the extremes of two adjacent curtains to the angles *a* and *c* of the square tower-fort A, a space would be left, *c a b*, unseen from the adjacent forts B and C, and therefore undefended, except by downward or vertical fire from machicoulis, or projections from the walls supported by corbels made for that express purpose. Such a space would be turned to account by the besiegers in fixing their scaling ladders; and the change of the straight line *ac* into the two faces *cb*, *ab* seems but the result of a self-evident necessity. As the work became enlarged, the portions of the fort within the connecting walls *m m* were omitted, and the flanks *dc*, *fa* alone remained of the old work, forming with the faces the bastion *fabcd*, which only required to be improved in proportions to become the bastion of modern times. It is, however, said that the towers were sometimes placed with an angle salient as in B, and if so, omitting the portions *n n*, the resulting bastion has a strong analogy to those of Errard before mentioned. By using the old wall merely as a retaining wall, and as an obstacle against escalade, and adding to it a rampart and a parapet of earth, the Italians completed the system of bastioned defence, which, notwithstanding all the modifications of the French, ought to be called the Italian system. In this system, whilst imitating the construction of the old towers by using casemated or masonry-vaulted chambers for artillery, in addition to the guns mounted on the rampart, the Italians placed the musketeers on the banquette of the parapet, and made them fire over it. Now this arrangement of the musketry fire is an essential characteristic of the Italian system, and the reliefs of the several works are hence restricted within certain limits, as it is necessary so to determine the levels of the opposite flanks that the fire along their superior slopes shall defend the whole of the intervening curtain: but there are other modes of using musketry as well as artillery fire in the defence of the ditches, and on these were founded other systems of fortification.

The first *Italian writer* on fortification was Tartaglia, whose work was published in 1546; but the really *first* writer on the science was Albrecht Dürer, at once a great painter, a sculptor, an engraver, and a civil and military architect, whose work is dated 1527, being published one year before his death. This remarkable man founded his system on the old circular tower-forts C, fig. 37, in which the dead space is much less than in the square, and enlarging them to an enormous extent, he adopted the word, "Bastei," or in the plural "Basteien," for his new work. As the attention of military men was at this early period more directed to cannon than to the rude musket as an instrument of defence, it was natural that the latter should be less considered in these arrangements than the former. Dürer based his systems on the principle that the defences of basteien or other works which depend only on the cannon placed on their terreplein, may be effective whilst the enemy is at a distance, but cannot be so when the enemy, under cover of his epaulements, has advanced to the ditch; and leaving therefore to the cannon on the terreplein the task of firing upon the enemy's troops and batteries at a distance, he placed his cannon, and it may be said also his musketry, either in vaulted galleries running along the base of the scarp, or in caponnieres, also vaulted or casemated works, built across or transverse to the ditch. The great circular bastei of his third and most improved system was no less than 130 yards in diameter, with a scarp 120 feet high, a ditch in front 100 feet wide, and a massive envelope, about 80 feet thick and 100 feet high, formed of earth with thick masonry revêtements both in front and in rear, as a mask between the main work and the counterscarp. Such gigantic proportions as these have led many to consider Dürer as little more than a speculative writer, but this would be an unjust estimate of his real merits. Reducing his works to more reasonable dimensions, they would, with proper modifications, have become practicable, and have afforded many useful hints to the scientific engineer. The defects of the circular form were compensated by the grazing fire of the caponnieres in his system, and the main work was retained in an effective state by the cover afforded to it by the envelope. We shall have occasion to refer again to Dürer, but in the meantime it may be said that whilst the Italians are properly considered the originators of bastioned systems with an earthen parapet over which the musketry fire is directed, Dürer has an undoubted claim to be considered the author of the other branch of fortification in which casemated defence in the main works, as also in caponnieres, becomes the essential characteristic—a branch which has proved as fertile in results in modern times as the bastioned system.

SYSTEMS OF PERMANENT FORTIFICATION.

1. *Vauban's First System.*

Before commencing to draw a plan of fortification, it is usual to determine upon some polygon on which to describe it. In this figure, accordingly (see Plate CCLX. fig. 1), we have taken the angle of an octagon, and called the length of the side 360 yards. In constructing a fortification, a figure is determined on, as near that of a regular polygon as possible, within which the enceinte or chain of main works is to be contained. The enceinte or body of the place consists of as many bastions, connected with curtains, as there are sides to the figure, and each of these is made as near 360 yards as possible, so that every part may be within range of such arms as are to be employed in its defence.

The *principal* or *outline* denotes the contour or line by which the first figure of the work is defined. This line is supposed to pass along the superior part of the cordon, and is that from which all the other parts of the work are set off.

The *exterior side*, or side of the polygon above mentioned as equal to 360 yards, is that upon which the front of the fortification is described, and it extends from the flanked angle of one bastion to the corresponding angle of the next, as AB. These lines are bisected, and a perpendicular, DC

is drawn from the point of bisection towards the place, its length being proportional to the extent of the exterior side and adjacent angle of the polygon; that is, one-sixth for the hexagon and all figures of a greater number of sides, one-seventh for the pentagon, and one-eighth for the square.

The *lines of defence* AEG, BEH, are drawn from the extremities of the exterior sides through these points, and produced to an indefinite length; and upon the lines so drawn are set off two-sevenths of the exterior sides, equal to 102$\frac{6}{7}$ yards, which marks out the point for the shoulder of the bastion E and F. The distance between these points is then laid along the continuation of each line of defence, and a line is drawn connecting them the curtain GH, from the extremities of which lines are drawn to the point marked off for the shoulder of the bastion, and thus form the flanks. And in this manner is drawn a front of fortification, which being repeated round the sides of the polygon, completes the works of the enceinte or body of the place.

Vauban divided his first system into three parts; namely, the little, the mean or intermediate, and the great. The first he used for small forts of four or five sides, citadels, horn-works, and crown-works, making the exterior sides from 120 to 240 yards, the perpendicular in the square equal to one-eighth, and in the pentagon one-seventh, and the faces of the bastions in each equal to two-sevenths of the exterior side. In the mean or intermediate, which is adapted for all sizes of towns, the exterior side varies from 250 to 360 yards, the perpendicular is one-sixth, and the faces are two-sevenths. In the great the exterior side varies from 360 to 520 yards. This kind was never adopted for *all* the sides of a place, but only when *one* of these happened to be near a river or a marsh; in which case the distances of the bastions should be so regulated that they may not be out of musketry range from one another. When the curtain becomes unavoidably too long, this defect is in part remedied by erecting on it a flat bastion, which is not so high as the rest of the works.

Ground which will admit of being regularly fortified throughout is seldom or never to be met with, but, nevertheless, the rules of regular fortification must be observed as nearly as possible; that is, the flanked angles should not be less than 60°, the lines of defence should not exceed musket range, and the sides should be lengthened or shortened so as to obtain a well-proportioned front upon each. After an irregular place has been reduced to as regular a form as possible, lines are drawn parallel at the distance of about 30 yards from the houses, in order to give sufficient space for the rampart; and these lines form the interior polygon, which may be fortified inwards, by setting off the demigorges of the bastions, and raising their flanks at an angle of 100° with the curtain: Or, the exterior side may be formed and fortified inwards by drawing a line parallel to each of the interior sides; and when the angle is that of a polygon of more than five sides, the distance from the exterior to the interior sides should not be less than 100 yards. If a side extend from 360 to 520 yards, the perpendicular should be diminished to about 50 yards, and the faces of the bastions be made from 100 to 120 yards. When a side is very long, it may be divided into several parts of from 340 to 360 yards each, which may be fortified with flat bastions, as was occasionally done by the Italians, an example of which may be seen in the bastion Anastasius at Corfu. All these dimensions may, however, be now much increased, and placed more in relation to the range of the modern musket.

The *ditch* or *fosse* is an excavation of from 12 to 24 feet in depth, and from 30 to 50 yards in breadth, surrounding the rampart on the exterior side, and the earth dug out of which serves to raise the rampart and parapet. The side of the ditch next the place forms part of the *escarpe*, the side next the country is called the *counterscarp*, and it is made circular opposite the salient angles of the works. In fig. 1 arcs are described with a radius of 30 yards, opposite the salient angles of the bastions, tangents to which are drawn upon the shoulders of the neighbouring bastions, and thus form the ditch. The general dimensions of a ditch should be such that its excavation, or deblai, would produce sufficient earth, or remblai, for the formation of the works. The breadth varies from 30 to 50 yards, in order that, in passing across it to the assault, the enemy may, for a considerable time, be exposed to the fire of the works; and its depth must also be such as to render difficult the escalade of the parapet, as well as to prevent the besiegers at the crest of the glacis from being able to see to breach the lower part of the revêtement of the escarpe. The line of the counterscarp is drawn from the rounding at the salient angles of the bastions upon the shoulders of the bastions next adjoining, in order that the whole of the ditch may be defended by the fire of the flanks of the collateral bastions. Ditches are of three kinds; wet, dry, and such as may occasionally be rendered either wet or dry. The wet ditch is calculated to prevent sudden surprises or assaults, excepting during hard frost, as in the attempt made to surprise Bergen-op-Zoom in the year 1814; but, independently of this exception, the number of bridges of communication, which require continual repair, and the difficulty of making sorties, which a wet ditch creates, renders it extremely inconvenient. A dry ditch, which is capable of containing works for its own defence, and by means of which communications round the works may more easily be maintained, is therefore preferable to a wet one; but the third kind, which unites the advantages of the other two, should, when practicable, be preferred to either. It is only in particular situations, however, that the advantage of such a ditch can be obtained.

The *tenaille*, in the form given to it by Vauban, does not appear in the works of earlier engineers, but it seems to be naturally derived from the trace of Rimpler (1673), in which the *middle flank* is analogous in function to the tenaille, and occupies its position; it is a work placed in front of the curtain, and is formed by the continuation of the lines of defence, at the distance of ten yards from the angle of the shoulder; the ends are then drawn parallel to the flanks of the bastions; it is made sixteen feet broad; the angle formed by the meeting of the two lines which determine its rear is then cut off, at the distance of ten yards, parallel to the curtain; and another line is drawn at the distance of sixteen yards, parallel to this, and forming a small curtain upon the line of defence or front of the tenaille. The relief or height of the tenaille is determined by that of the neighbouring flanks, and it has a parapet of seven or seven and a half feet in height, and from twelve to fifteen feet in thickness. The use of the tenaille is to cover the postern gate, which is often made in the curtain or flank, when the ditch is dry, to protect the troops who may be formed behind the work for the defence of the ditch; and when the ditch is a wet one, to cover the boats which may be collected for the same purpose. It also serves to augment the defence, as its fire, from being more horizontal, and nearer to the plane of the bottom of the ditch than that from the flanks, is of course proportionally more effectual.

The *ravelin* or *demilune* was a work originally designed to cover the entrance gate and ridge of a fortress, but it soon assumed the dimensions and performed the office of a most important work of defence, appearing as such in some early Italian traces. Speckle, the great German engineer, who fortified Schlottstadz, Hagenau, Ulm, Colmar, Bâle, and Strasbourg, was, however, the first who recognized fully its importance, and laid down as a rule that "great ravelins materially augment the defensive power of

a bastioned system." Acting upon this principle, the ravelins of Speckle were even larger than are those of Cormontaigne's system, and covered nearly the whole of the faces of the bastions, the faces of the ravelin being directed on the salients of the bastions and their capitals, extending about 150 yards in advance of the exterior side of the polygon. Speckle was another man of science, having studied mathematics and military engineering in his youth, and then perfected his knowledge by personally visiting and studying the most remarkable Italian fortifications existing in his time. The Ravelin is a work constructed opposite the curtain, and composed of two faces meeting in an outward or salient angle, with two demigorges formed by the counterscarp. Its use is to cover the curtain, the gates, and the flanks of the bastion. The ravelin is constructed as follows: eleven yards are set off along the faces of the bastion from the shoulder; an arc is described from the angle of the flank upon the perpendicular produced, with a radius of 160 yards; from this intersection lines are drawn bearing upon the points set off at eleven yards from the shoulders of the bastion, but not further than the lines of the counterscarp; and at the intersection of the lines of the counterscarp or re-entering angle six yards are set off on the capital or line bisecting its angle, whence lines are drawn parallel to the lines of defence till they meet those of the counterscarp. Stairs, called *pas-de-souris,* are constructed here in order to facilitate the entrance of the ravelin from the ditch. The ditch in the ravelin, which is twenty-four yards in breadth, is made circular at the salient angle, and drawn parallel to the faces till it joins the main ditch.

The *covered-way* was first described by Tartaglia in 1554, so that it must have been used at a very early epoch of Italian fortification. Some of the first bastioned fortresses were, however, without this highly important work; and it is recorded that at the siege of Vienna by the Turks, the garrison having made a sortie, some companies were pursued by the Turks up to the counterscarp, and forced over it into the ditch. The necessity of being able to assemble the troops intended for a sortie *under cover* from the enemy's fire, and to afford them when repulsed a place for reforming and checking the enemy's progress, and thus insuring an orderly retreat into the body of the place, soon became apparent, and a covered-way was supplied to works originally constructed without one. It is a space of ten yards in breadth, extending all round the counterscarp of the ditch, and covered by a parapet of from seven to nine feet in height, with a banquette. The superior part of this parapet forms a gentle slope towards the country, which terminates at the distance of from forty to seventy yards; and this slope is called the *glacis.* The covered-way serves for drawing up troops in order to make sorties, and costs less than any other part of the works in proportion to the difficulty of taking it. In the salient and re-entering angles of the covered-way spaces are contrived which have been denominated *places of arms.*

The *salient places of arms* are formed by the circular parts of the counterscarp, and the prolongation of the branches of the covered-way till they intersect. The *re-entering places of arms* are constructed with two faces, forming a salient angle of 100° with the covered-way. The demigorges of the re-entering places of arms are generally from twenty-four to thirty yards; but when they are intended to contain a redoubt or intrenchment, they are from forty to forty-eight yards. The re-entering places of arms are meant to flank the branches of the covered-way, and to contain the troops for its defence. The salient places of arms also serve for assembling the troops destined to defend the covered-way.

Traverses are constructed across the covered-way, upon the prolongation of the sides of the ravelins and bastions, perpendicular to the line of the counterscarp; they are from eighteen to twenty feet thick, and serve to cover the troops from the enfilading fire of the enemy. Other traverses should be constructed between these, so that the distance from the one to the other should not exceed thirty-six or forty yards. Openings are cut into the parapet of the covered-way about ten or twelve feet wide, in order to keep up the communication from one part to another round the ends of the traverses, which, however, may be shut by a gate when required. In the more improved systems of Cormontaigne and others, these passages are constructed in such a manner that each can be defended by the fire from the traverse in rear of it.

The *glacis,* as already stated, forms a gentle slope or declivity from the parapet of the covered-way towards the country, and varies from forty to sixty yards. Its parapet cannot be ruined by the fire of the enemy; it covers the revêtement of the body of the place; and being an inclined plane, it can be easily seen and defended from any part of the works.

The *rampart* is an elevation of earth, being the part of the works situated next to the town. It must be thick enough to receive a mound of earth, called the parapet, and also leave sufficient space behind it for working the guns, as well as room for the defenders to pass round freely. The ditch is immediately in front of the rampart, the faces of which are revêted or built up with stone walls, backed interiorly, at every fifteen or twenty feet, by buttresses or counterforts of masonry, to strengthen it. The rampart is divided into the *interior slope,* the *terreplein,* the *banquette,* the *parapet,* and the *exterior slope* or *escarpe.* See fig. 4, *profile.*

The *revêtement* or face of masonry around the work on both sides of the ditch is intended to prevent the earth forming the rampart from falling into the ditch. To ascertain the proper thickness of masonry for this purpose has always been a work of considerable trouble and difficulty. General Sir Charles Pasley of the royal engineers has given the following rules: 1st, For full-scarped revêtements without berms, and for demi-revêtements having berms equal to one-fourth the height of the masonry, the thickness of the wall should be seventeen-sixtieths, and the length of the counterforts or buttresses one-fifth of their height. 2dly, For demi-revêtements without berms, the mean thickness of the wall should be three-tenths, and the length of the counterfort one-fifth of the height. 3dly, For counterscarp revêtements, having only to retain simple terrepleins, the mean thickness should be one-fourth, and the counterfort one-sixth of the height. In all these cases Colonel Pasley supposes the revêtement to be countersloped, that is, to have the exterior slope in a vertical plane, and the interior face inclined, so that the base of the wall may be broader than its upper surface by one-fifth of its height; and he also supposes the counterforts to be rectangular, and the intervals between their centres to be equal to four times their width. 4thly, He recommends that the foundations be made deeper in rear than in front, and that the courses of masonry form an angle with the horizon of about 10° excepting at the exterior points, where it should be made horizontal, to prevent the rain from penetrating, and that the interior face of the wall should be of an irregular form. In order to diminish the lateral pressure of the earth against the revêtements, several tiers of arches may be built between the counterforts in the form of segments of a circle.

The *cordon* is a round projection of stone, about a foot in diameter, which goes quite round the revêtement wall, near the top, and serves to throw the drip of rain off the face of the masonry. It is also a considerable obstacle to besiegers, in placing their ladders for escalade against the escarpe.

The *profile* or *section* of Vauban's first system is given

in Plate CCLX., fig. 4, in order to illustrate the relative relief or height of the respective works, and also to show the command which each has over the others. When the height of the rampart, including that of its parapet, is 20 feet, and that of the parapet of the covered-way is 9 feet above the plane of the site, then the rampart will have a command of 20 feet over the country, and 11 feet over the crest of the covered-way; and the latter, again, will have a command of 9 feet over the field. There are three sorts of command, namely, in front, in rear, and in enfilade. That in front is when any eminence directly faces the work which it commands; that in rear is when the eminence is behind the work; and that in enfilade is when the eminence is situated laterally on the prolongation of any line or work. The last, which is the most dangerous kind of command, is best remedied by raising the salient of works exposed to it (see woodcut 18, p. 775), or by erecting traverses. In drawing this figure, a line, called the line of site, and supposed to be the surface of the ground on which the fortification stands, is drawn, and perpendiculars are erected on it equal to the respective heights of the different parts of the works corresponding to the lines in the figure. Thus *a* shows the terreplein of the rampart, *b* the banquette or step to enable the soldiers to fire over the parapet, *c* the parapet, *d* the revêtement, *e* the escarpe, *f* the counterscarp, and so on.

2. *Vauban's Second and Third Systems.*

Having thus endeavoured to explain, with as much minuteness as possible, the principles of Vauban's first system, we trust, from what has been said, that no great difficulty will be experienced in understanding the methods of other engineers who have constructed works varying but little in the main from those prescribed by this system, whilst even these varieties have arisen from difference of situation and local peculiarities, more than from any other cause. The same general observation, indeed, applies to the other methods of construction followed by Vauban himself, who, in his second and third systems (Plate CCLX. fig. 2), merely modified, according to circumstances, the principles upon which the first is based. When this celebrated military engineer was called upon to repair or improve the fortresses of Landau, Brisach, and others, and found these places already surrounded with strong walls surmounted by small towers at the angles, he did not, as some might have supposed, proceed to destroy these defences, but, with his accustomed judgment and ability, he immediately took advantage of them, and constructed, nearly in the same proportions as in his first system, large counterguards or bastions in front of the towers which crowned the angles of the wall, just as the Italian Castriotto had done in 1584. And by this method an important object was attained; for, as in front of each tower, or rather tower-bastion, there ran a ditch which cut off all communication between it and the counterguard, so the enemy, even if they should have succeeded in establishing themselves in the counterguard, would still have another ditch to cross, and another wall to breach, before they could attempt to give the assault.

There is so little difference between the second and third systems of Vauban, that a description of the former will be sufficient to enable the reader to distinguish and appreciate the peculiarities of the latter. In the second system, the interior side of the polygon, from the centre of one tower-bastion to that of the next, is supposed to be equal to 240 yards, and from its extremities, at the distance of 24 yards, perpendiculars are erected equal to 36 yards, for the flanks of the tower-bastions. A line is then drawn parallel to the interior side AB, till it meets the oblique radius of the polygon, or line drawn from the centre of the polygon bisecting its angle, and this being done on both sides of the angle forms the tower-bastion. The oblique radius is then produced 78 yards, and lines of defence are drawn to the angle where the tower-bastion joins the curtain or line AB. On these lines of defence, the faces of the counter-guard, or exterior bastion, are set off equal to 128 yards, and from the point forming the shoulder, flanks are directed to a point set off on the line AB, at the distance of 70 yards from its extremities. From the salient angles of the tower-bastions arcs are described with a radius of 14 yards for the breadth of the ditch, and tangents to these arcs are drawn parallel to the faces of the tower-bastion, but stopped where they would meet a line drawn from the salient angle of the tower-bastions, at the distance of 20 yards from the flanks.

The *tenaille* is the same as in the first system, excepting that, at its ends, it is carried down till it meets the line drawn between the flanked or salient angles of the tower-bastions. The *ditch* in front of the counterguards, or, in other words, the main ditch, is constructed in the same manner as in the first system. The *ravelin* is formed by setting off 90 yards from the re-entering angle of the counterscarp, and directing its faces to points set off on the counterguards, at the distance of 20 yards from the shoulders. A flank is formed by cutting off the corners of the ravelin at the distance of 14 yards on its demigorge, and 20 on its face; and this flank serves for the placing of guns in such a manner that their fire may be directed into the counterguard, or into the ditch before them, as occasion may require. Again, at the distance of 48 yards from the re-entering angle of the counterscarp, lines are drawn parallel to the faces of the ravelin for the *redoubt;* a ditch is formed in front of this, and parallel thereto, about 18 feet in breadth; and the redoubt thus constructed has a command of 4 feet over the parapet of the rampart, as the tower-bastions have over the counterguards. The *covered-way* and *glacis* are formed as in the first system. It sometimes happens that redoubts are constructed in the re-entering places of arms; in which case their demigorges are made from 15 to 40 yards, and their faces set off at an angle of 100 degrees, as before.

3. *Cormontaigne's System.*

The difference between the systems of Vauban and Cormontaigne may easily be discovered by an examination of Plate CCLX., fig. 3. Vauban makes the faces of his bastions two-sevenths of the exterior side, and Cormontaigne one-third. Vauban, in his first system, produces the faces of his ravelin to the distance of 11 yards upon the face of the bastion from the shoulder, and in his second and third systems, to the distance of 20 yards; but Cormontaigne makes the capital of his ravelins about 120 yards, and produces the faces to the distance of 30 yards from the shoulder; by which means the flanks are better covered, and the bastions and ravelins are enlarged. And this is an advantage; for he is thus enabled to construct a larger redoubt in his ravelin, the curtain and flank are also better covered, and, as the former is shorter, communications are more easily kept up between the bastions. Cormontaigne gives the same breadth to his covered-way as Vauban, but he arranges in a different manner the communication round the extremities of the traverses, as may be seen by inspecting the plate. By this zigzag line of communication, which resembles the cremaillière trace adopted by Speckle in his covered-way, the passage round the extremity of one traverse may be defended by the fire of the other in its rear, or nearer to the body of the place, and the advance of assailants along the covered-way completely checked. As Speckle planned in 1589, or long before the invention of ricochet fire by Vauban had rendered traverses an essential element in fortification, his object was not the same as that of Cormontaigne, but simply to ensure a more perfect flanking defence of the branches of the covered-way than that afforded by the places of arms of his systems. The ditches are, as shown in fig. 3 of this Plate, on different levels—the main ditch being about 23 feet deep, the ditch of the re-

doubt of the ravelin only 7 feet, so that from this latter ditch there is a fall of 16 feet to the main ditch, rendering it impossible to attack the ravelin by its gorge without the aid of ladders. An examination of the several figures which represent Vauban's and Cormontaigne's systems, as also the outworks of fig. 3, Plate CCLXI, will at once render evident the vital defect of the ordinary arrangements of outworks—that they expose by their ditches the scarp of either the body of the place, or of the work on which their faces or branches are directed, to be breached. In the system of Cormontaigne, as well as in the modern system next to be considered, the increased projection of the ravelins, by throwing the intervening bastion into a deeply re-entering position, secures it from attack by approaches until the salients of the ravelins have been taken; but this great advantage is diminished by the power of breaching the bastion from the glacis through the opening afforded by the ravelin. For the purpose of covering the communication to the re-entering place of arms, a *demi-caponnière*, or work composed of a parapet and glacis, was thrown across the ditch of the ravelin, as shown in the figure of the modern system, Plate CCLXI., fig. 2. This work afforded cover also to troops assembling preparatory to a sortie upon the enemy when making the passage of the ditch, but, from the depth of the ravelin ditch, it was insufficient to mask the revêtement of the bastion behind it. It will presently be shown how this object was afterwards effected; and it may be fairly said that without any material change as to system, the general result of Cormontaigne's variations from Vauban's trace is an unquestionable improvement.

4. *The Modern System.*

The modern system, which is shown in Plate CCLXI. fig. 2, varies but little from Cormontaigne's. Its perpendicular is one-sixth of the exterior side, and the faces of the bastions are one-third. The flanks are at right angles with the lines of defence, whereas in Vauban's system they form an angle of about eighty-two degrees; which is not so good, because, in the modern system, the guns placed in the flanks can fire straight along the ditch without being moved or turned on their platforms. The ravelin is formed by setting off thirty-four yards from the shoulder angle of each bastion along the face, which line forms one side of an equilateral triangle, the vertex of which, opposite the centre of the curtain, forms the salient angle of the ravelin. The redoubt of the ravelin is formed by drawing its faces parallel to those of the ravelin from the shoulder angle of the parapet of the bastion; and it has flanks with a ditch about twenty yards in breadth. The *cavalier* in the bastion is drawn parallel to the faces of the bastion, at the distance of forty-eight yards. The ditch on the faces is ten yards in width, but there is no ditch on the flanks. The *coupure* connected with the cavalier retrenchment is drawn perpendicular to the faces of the bastions, at thirty-four yards for the counterscarps of the coupures, whilst the scarps are at ten yards, and parallel to these. This system originated in the School of Military Engineering instituted at Mézières in 1750, and was for some time called the System of the School of Mézières. It has, however, been successively much improved; and the system which is now recognised as the modern system is that of General Noizet. Referring, however, to fig. 2 of the Plate, it will be seen that coupures have been introduced on the faces of the ravelin; and as the ditch of the ravelin in this system has by many engineers been sunk less by 7 or 8 feet than the main ditch, there is a sufficient fall between the two to check the enemy in his passage to the latter, whilst the demi-caponnière is raised so much higher, and therefore begins to mask more effectually the revêtement of the bastion. In General Noizet's system this demi-caponnière is formed into an elevated mask, which effectually secures the revêtement from the breaching effect of the fire from the enemy's battery on the crest of the ravelin glacis. This is shown in the annexed woodcut; and the system modified from the former modern system in this respect, as well as in other arrangements, is now the normal bastioned

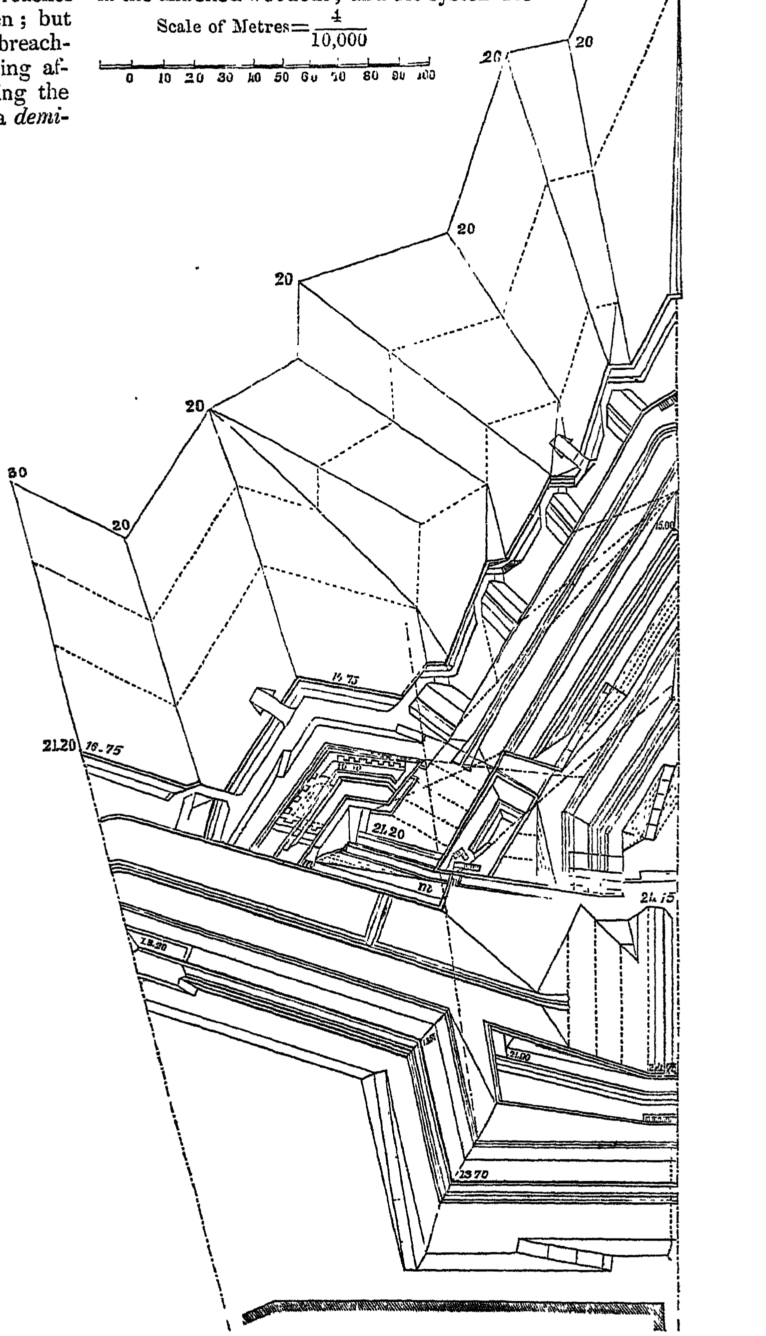

Fig. 33.

system of all the French schools. In General Noizet's arrangement the flanks are not made perpendicular to the lines of defence, but, as in Vauban's first system, the flank forms an angle of about 80° with the line of defence. In the citadel of Ghent, which is a most beautiful example of this system, with still further modifications, the retrenchment of the bastion is so formed as to take advantage of this construction, and the flanks being casemated and pierced in both directions, they become on one side the flanks of the retrenchment, whilst on the other they are the ordinary flanks of the bastion, thus giving a much longer curtain to the retrenchment than in the form exhibited in fig. 3 of Plate CCLXI., as it occupies the whole gorge of the bastion.

5. *Outworks.*

Plate CCLXI., fig. 3, shows several kinds of outworks, as a horn-work *g*, tenaillons *k* and *k*, bonnet *d*, lunettes *a* and *d*, an entrenched bastion *e*, batardeau *f*, and caponnière *h*. These, and other works of a similar description, are constructed for the purpose of occupying some of the ground which might otherwise be of service to the besiegers, or as in the caponnière to cover a communication; but their application must of course depend upon certain localities, and the judgment of the engineer must therefore determine, in each particular place, which is best adapted to the ground, and most proper to be employed with reference to the general defence of the place.

ARMAMENT OF FORTRESSES.

Having thus described, though briefly, the systems of fortification which, mainly depending on the principles first adopted by the early Italian engineers, may be considered the result of the gradual development of these principles in the more mature and skilful arrangements of successive engineers, it is right before describing other systems to say a few words respecting the means of defending a place after it has been fortified. And here we may observe, that it is difficult to lay down any exact rules as to the proportion of ordnance, ammunition, and stores of every kind required for the defence of a fortified place, seeing this must necessarily vary according to the particular situation of each fortress, the system on which its works have been constructed, and the species of attack to which it may be exposed. If, for example, one of the sides be covered by a morass, swamp, or any other obstruction which it is difficult or perhaps impossible to surmount, it must be obvious that, in this case, a smaller proportion of artillery will be required than if the fortress were equally accessible on every side; and, on the other hand, a maritime fortress, accessible at all points, will necessarily require for its defence a larger proportion of ordnance than if it were only assailable on one or a few of these points. Where every front is equally exposed to attack, all must of necessity be equally prepared.

On this subject, however, there have been established certain maxims, of which the following appear to be the most important: First, the proportion of ordnance, ammunition, and stores, should never exceed the quantity necessary for a brave and resolute defence. Secondly, those points which are considered as being most exposed to attack should be most completely armed, whilst the partial armament of the remaining points may suffice. Thirdly, for each of the faces of the bastions which are liable to be attacked, five or six pieces of ordnance should be allotted; for each of the flanks of these bastions, four; for the faces of the ravelins, from five to seven; for the lunettes, when there are such, four pieces of ordnance should be reckoned; besides two or three pieces for each of the places of arms in the covered-way. Supposing, therefore, that one front of a place is to be completely armed, the proportions of ordnance required will be, for the faces of the bastions from ten to twelve pieces, for the two interior flanks from six to eight, for the faces of the ravelins from five to seven, and for five places of arms from ten to fifteen; making the total of ordnance for one front from thirty-one to forty-two pieces. Fourthly, when a place is exposed to attack on two consecutive fronts, the armament of each should be augmented one half; when it is threatened with attack on detached fronts, the armament should, in that case, be doubled. Fifthly, each of the other fronts should merely be provided with such a proportion as to secure it against insult. Lastly, from the foregoing maxims, it appears that a hexagon, having only one front exposed to attack, requires from fifty-eight to sixty-eight pieces of ordnance on such front, whilst in more extensive places, six, eight, or ten pieces should be added for each additional front. For the present increased power of the ordnance brought into the field this proportion should be increased by about $\frac{1}{10}$th of the total number.

The next consideration is the proportion which the several kinds of ordnance should bear to one another. And here let it be remembered that ordnance of the higher calibres is not the only description which ought to be employed. In many cases medium and even light guns are more efficacious; for when only troops or working parties are to be fired at, light guns will answer every purpose, as the range of the shot is nearly equal to that of larger guns, and they are of course much more manageable, and may be worked with greater rapidity. But short guns of heavy calibre are best adapted for the flanks; and, generally, the large or heavy ordnance should only be employed to destroy the besiegers' batteries and dismount their guns. The flank guns being only required for the defence of the ditch, short pieces of large calibre, as carronades, which throw a heavy charge of grape or canister shot, are the most proper to be employed. The light guns, as they can easily be withdrawn, should be placed on the covered-way and places of arms, and on outworks of every description. The heavy long guns and mortars, as they are not so easily moved, should be within the body of the place, and as they require a great quantity of ammunition, they should be less frequently used, and only upon urgent occasions. A judicious economy of ammunition is a duty incumbent upon every governor or commandant of a fortified place attacked. The conduct of General Chassé in the defence of the citadel of Antwerp was a model in this respect. From the commencement till the close of the attack, scarcely a single shot was needlessly expended by the garrison.

ATTACK AND DEFENCE OF FORTIFIED PLACES.

Having thus treated of that important branch of fortification which is denominated permanent, and which, being applied solely to the defence of towns, is not liable to be destroyed except by an enemy, we now proceed to consider the attack of fortified places, the general system of which was introduced by Vauban, and so far perfected by that great engineer that it has ever since served as a model for the plans of his successors.

"La résolution des sièges," says the Mareschal, "est une affaire de cabinet. Elle est une suite naturelle de la supériorité que l'on croit avoir sur ses ennemis; mais leur exécution étant une des plus sérieuses, des plus importantes, et des plus difficiles parties, elle demande aussi le plus de mésure et de circonspection." He then goes on to state that the success of sieges depends on several circumstances, such as, "1. Du secret, sans lequel il est difficile de réussir: 2. Des forces que l'on a sur pied pour attaquer les places des ennemis, et défendre les siennes: 3. De la disposition des ennemis; car s'ils sont réunis, et aussi forts que nous, ils peuvent nous empêcher d'en faire: 4. De

l'état des magazins les plus à portée des lieux sur lesquels on peut entreprendre: 5. De la conjoncture des tems, parce que tous ne sont pas propres aux sièges, et rien n'étant plus ruineux que ceux d'hyver, on les doit eviter tant qu'on peut: 6. Des fonds nécessaires à leurs dépenses; car l'argent est le nerf de la guerre, sans lui on ne sçauroit réussir en rien. Ce sont là des mésures à prendre de longue main, qui doivent être dirigées à loisir; et aprés tout cela, quand on croit les avoir bien prises souvent tout échappe; car l'ennemi, qui n'est jamais d'accord avec vous, pourra vous interrompre..... Il faut bien peser toutes ces considérations, avant que de se déterminer; et prendre toujours si bien son tems, que l'ennemi ne puisse vous tomber sur les bras avant vos établissemens."[1]

A siege, therefore, being one of the most arduous undertakings in which an army or corps d'armée can be employed—one in which the greatest fatigue, hardships, and personal risk are encountered, and in which the prize can only be won by complete victory; it is obvious that, upon the success or failure of such an enterprise may depend the fate of a campaign, sometimes that of an army, and perhaps even the existence of a state. Of this the failures before Pavia in 1525, before Metz in 1552, before Prague in 1557, before St Jean d'Acre in 1799, and before Burgos in 1812, present instructive examples. By the first, France lost her monarch, the flower of her nobility, and all her Italian conquests; by the second, she was saved from destruction, whilst thirty thousand of her enemies perished; by the third, the greatest warrior of his age, Frederick the Great, was brought to the very brink of destruction; by the fourth, the most successful general of France, and perhaps the greatest commander that any age or country has produced, was stopped short in his career of victory; and by the last, a beaten enemy gained time to recruit his forces, concentrate his scattered corps, and regain that ascendancy of which the victory at Salamanca had for a time deprived him. Innumerable other instances of the disastrous consequences usually attendant on the failure of sieges might easily be produced; but those which have just been referred to are sufficient to establish the importance of the undertaking, and to show that the dearest interests of a country may frequently be staked on the sure and speedy reduction of a fortress.

It is therefore of the greatest importance to a state that the sieges undertaken by its armies should be carried on in the best and most efficient manner possible, or, in other words, that by a due combination of science, labour, and force, these operations should be rendered not only short, but certain, and unproductive of any great expenditure of life. But the sieges undertaken by the British have almost never united these three indispensable conditions; and with regard to those which took place during the contest in the Peninsula, it is well known that various defects of organization, and particularly the want of a body of men such as sappers and miners, trained to the labour required at sieges, and an inadequate supply of matériel, necessitated a partial departure from established principles and rules of attack, and consequently led to a waste of life wholly unprecedented in modern sieges. Till late in 1813 the army was unattended by a single sapper or miner: regular approaches were therefore difficult if not impracticable: it was necessary, in almost every case, to take the bull, as the saying is, by the horns; the last operation of a siege scientifically conducted, namely, battering in breach, was amongst the first undertaken: and the troops were marched to the assault whilst the defences remained nearly entire, and exposed to every species of destruction which the unreduced means of the besieged could bring to bear against them. The army of a country which has outstripped all others in the useful arts and in mechanical improvements, was left wholly unprovided with those appliances which at once economise labour and life, and serve to render both most effectual for the purposes to which they are applied. But, notwithstanding this great anomaly, which is chargeable against the government alone, and not against either the nation or the army which in the most adverse circumstances so nobly sustained its reputation, it may be observed that, in all periods and in all countries, the means employed for the reduction of fortresses have generally increased and become more overwhelming and irresistible in proportion to the advancement of knowledge and the improvement of the useful arts; and that in Europe during the last two centuries, the extensive diffusion of wealth and knowledge, accompanied by an unprecedented development of talent, all more or less directed towards military movements, has caused the results of sieges, and indeed of almost all the operations of war, to depend much less on individual exertion or casual displays of heroism, than on mere combination and expenditure. This may be made apparent by a slight retrospect of the sieges of the sixteenth century.

At the period here referred to, the art of disposing the several works of a fortress so as to cover each other, and to be covered by their glacis from the view of an enemy, was either unknown or disregarded; whilst the small quantity of artillery in use, its unwieldiness, and the great expense and difficulty of bringing it up, occasioned so little to be used in sieges, that the chief object in fortifying towns was to render them secure against escalade and surprise, by means of lofty walls or altitude of situation. All places fortified prior to the sixteenth century are invariably of this construction. And as the simplicity of the fortresses to be attacked necessarily gave the same character to the operations directed against them, so, in those days, everything was effected by daring courage, without the aid of science; and gallantly contending in individual combat, or fearlessly confronting danger, were considered as the highest qualities of a besieger. Thus the contest dragged on for months, in petty but sanguinary affairs, and the most persevering or the most hardy troops, however ill organised or supplied, were the most dreaded, and not unfrequently the most successful. But when artillery became more moveable, and large quantities began to be employed in sieges, lofty and exposed walls no longer opposed any adequate barrier; large breaches were speedily effected; places which had formerly resisted for months were carried in a few days; and hence, in order to restore an equality of defence, it became necessary to screen the ramparts from distant fire. The attempt to gain security by concealment rapidly advanced towards perfection, whilst the means of the besiegers remained the same; and between the middle of the sixteenth and commencement of the seventeenth century, works were so skilfully disposed and so well covered, that the defence of towns obtained a temporary superiority over the attack as the latter was then practised. Of this the obstinate and successful defences made by the Dutch against the Spaniards during the reigns of Philip II. and Philip III. may be cited as remarkable examples.[2]

The pre-eminence of the defence over the attack was mainly due to the great difficulty of dragging up heavy ordnance with a besieging army, so that the weight of metal being generally in favour of the besieged, the fire of the fortress was enabled to keep in check that of the batteries of attack. Vauban, however, in the reign of Louis XIV., restored the preponderance of power to the attack by the invention of ricochet fire, as the guns of the besieged were

[1] *De l'Attaque et de la Défense des Places*, pp. 1 and 2. Hague, 1737, 4to.
[2] *Journals of Sieges in Spain*, by Colonel Sir John T. Jones; *Preliminary Observations on the Attack of Fortresses.*

thereby dismounted or disabled at an early stage of the siege, and the besiegers were enabled to push forward their approaches by the sap, being relieved in great measure from the dangers and difficulties of a direct and powerful opposing fire of artillery. Vauban also matured into a system the attack by laying down rules for the establishment of parallels, for the location of enfilade and other batteries, and for the general conduct of the approaches. The real type of an attack is a *moving parapet*, the besieger carrying on with him his cover, and thus depending for his success not so much on his offensive as on his defensive arrangements. It was by this combination of science and labour, aided by the steady advances of brave and well-trained sappers, that the reduction of fortresses, which would have resisted for ever the rude assaults of the most determined enemy, was rendered comparatively easy and certain.

These increased means of attack, to which it was found impossible to oppose a successful resistance, caused the art of concealment or covering to be further studied, till at length, in well-constructed fortresses, not a single wall remained exposed to view, and the sap and the mine became as necessary as the gun and the mortar to the success of a besieger. To render this intelligible to the general reader, it may be proper to introduce here a descriptive sketch of the progress of a modern attack, from the excellent work of Sir John Jones, already referred to.

"The first operation of a besieger," says that able and experienced engineer, "is to establish a force able to cope with the garrison of the town to be attacked, at the distance of six or seven hundred yards from its ramparts. This is effected by approaching the place secretly in the night with a body of men, part carrying entrenching tools, and the remainder armed. The former dig a trench in the ground parallel to the fortifications to be attacked, and with the earth that comes out of the trench raise a bank on the side next to the enemy, whilst those with arms remain formed in a recumbent posture, in readiness to protect those at work, should the garrison sally out. During the night this trench and bank are made of sufficient depth and extent to cover from the missiles of the place the number of men requisite to cope with the garrison, and the besiegers remain in the trench during the following day, in despite of the fire or sorties of the besieged. This trench is afterwards progressively widened and deepened, and the bank of earth raised till it forms a covered road, called a parallel, embracing all the fortifications to be attacked; and along this road, guns, waggons, and men securely and conveniently move, equally sheltered from the view and the missiles of the garrison. Batteries of guns and mortars are then constructed on the side of the road next the garrison, to oppose the guns of the town, and in a short time, by superiority of fire, principally arising from situation, silence all those which bear on the works of the attack. After this ascendancy is attained, the same species of covered road is, by certain rules of art, carried forward, till it circumvents or passes over all the exterior defences of the place, and touches the main rampart wall at a spot where it has been previously beaten down by the fire of the batteries erected expressly for the purpose in the more advanced parts of the road.

"The besiegers' troops being thus enabled to march in perfect security to the opening or breach in the walls of a town, assault it in strong columns; and being much more numerous than the garrison defending the breach, soon overcome them, and the more easily as they are assisted by a fire of artillery and musketry directed on the garrison from portions of the road only a few yards from the breach; and which fire can, at that distance be maintained on the defenders of the breach until the very instant of personal contention, without injury to the assailants. The first breach being carried, should the garrison have any inner works, the covered-road is by similar rules of art pushed forward through the opening, and advanced batteries are erected in it to overpower the remaining guns of the place; which effected, the road is again pushed forward, and the troops march in security to the assault of breaches made in a similar manner in those interior works, and invariably carry them with little loss. But as it is always an object to preserve the life of even a single soldier, so, when time is abundant, the loss of men attendant on the assault of breaches under these favourable circumstances may be avoided, by pushing up the covered-road through the breach, without giving the assault, and thus, by art and labour, the strongest defences frequently fall without any exertion of open force."

From this description it must be obvious that the most important object at a siege is to carry forward the covered-road to the walls of the place; that all the other operations are secondary to and in furtherance of such an advance; and that hence the efficiency of armies at sieges depends upon their ability to complete the road at a small expense of life. But in forming this covered-road, different degrees of difficulty are experienced in proportion as it advances. At its commencement, the work being about six hundred yards from the fortifications, can easily be performed by the common soldiers. But when the road or trench has arrived within a fair range of musketry, or three hundred yards from the place, then particular precautions are required; yet the work at this stage is not so difficult as to prevent its being executed by soldiers who have had a little previous training. At the last stage, when the approaches have been pushed close to the place; when to be seen is to be killed; when mine after mine blows up the head of the road, with every officer and man on the spot; when the space becomes so confined that little or no front of defence can be obtained; and when the enemy's grenadiers sally forth every moment to attack the workmen, and deal out destruction to all less courageous or weaker than themselves; then the work becomes truly hazardous, and can only be performed by selected brave men, called sappers, who have acquired the difficult and dangerous art from which they derive their name. An indispensable auxiliary to the sapper, however, is the miner, who, in the exercise of his art, requires even a greater degree of skill, conduct, and courage. The duty of a miner at a siege is to accompany the sapper, to listen for and discover the enemy's miner at work, and to prevent his blowing up the head of the road, either by sinking down and meeting him, in which case a subterranean conflict ensues, or by running a gallery close to that of his opponent, and forcing him to desist from working by means of suffocating compositions, and various arts of chicanery, the knowledge of which he has acquired from experience. Without the aid of skilful miners, sappers would be unable to execute that part of the covered-road forming the descent into the ditch, not to mention other operations in the progress of which the assistance of the miner is equally indispensable; and without their joint labours and steady co-operation, no besiegers' approaches ever reached the walls of a fortress. In the British service, indeed, they are blended into one honourable body, the Sappers and Miners.

But a siege, though it calls for great personal bravery, unremitting exertion, and extraordinary labour in all employed, yet, if scientifically prosecuted, is alike certain in its progress and its result. More or less skill and exertion in the contending parties may in some degree prolong or abridge its duration; but the sapper and the miner, when skilfully directed and adequately supported, will ultimately surmount every obstacle. On the other hand, sieges undertaken by armies imperfectly supplied with these auxiliaries, as the British army once was, are hazardous in the extreme. Their only chance of success consists in scrutinizing the exterior of a fortress, in order to discover some spot whence, from the irregularity of the ground, or fault of con-

struction, the main escarpe wall may be seen at a distance sufficiently great to enable the ordinary working parties to approach with the covered-road, and there to establish batteries for breaching the wall or forming an opening through it into the place. When this is effected, the troops at once advance to the assault of the breach, as in the sixteenth century, thus losing the shelter of the covered-road at the moment when the fire of the place becomes most powerful and destructive; and as the fire of the besieger's distant batteries is necessarily suspended during the assault, in order to avoid killing their own storming party, the garrison can therefore with impunity mount their ramparts and employ every kind of weapon, missile, and instrument in their defence. All the chances are thus in favour of the besieged; for should the columns of attack, under all these disadvantages, arrive in good order at the brink of the ditch, they must descend into it by a wall from fourteen to sixteen feet in depth, which cannot fail to break their order and throw them into confusion; and as no new formation can be attempted in a spot where death is incessantly showering down on them, the assailants rush to the breach more like a rabble than a solid column. From this moment success hinges on the individual and confident bravery of the officers and troops, and the unshrinking firmness of the general commanding, in at once encouraging and supporting their efforts. But although these qualities, when united in a high degree, may, at a great sacrifice of life, enable the assailants to overcome all resistance, yet an assault of this nature, attempted under ordinary circumstances and feelings, has almost invariably proved unsuccessful. Indeed it may be laid down as the general result of experience, that should an army unprovided with sappers and miners, and the necessary materials and means to render their services efficient, be opposed to a place fortified according to the modern system, with its walls completely covered, all the usual methods to reduce it would prove unavailing; no period of time nor sacrifice of men would be sufficient to purchase success, and the prudent course would be to decline an attempt pregnant with hazard, perhaps ruin.

"These considerations," says Sir John Jones, to whom we are indebted for the above account of the various modes of attacking fortified places, "have for many years had their due weight with the great powers of Europe, and induced them to form and keep up, as integral portions of their military strength, every necessary auxiliary for the reduction of fortresses; and their sieges have in consequence become certain and comparatively bloodless. But England, constitutionally jealous of permanent military establishments, always discountenanced military organization and military preparation till the hour of need; and with respect to sieges, they being of rare occurrence, and moreover exclusively offensive operations, even carried her jealous feelings beyond the bounds of rational prudence; for, possessing a corps of officers professionally educated and well grounded in the science of attack and defence, she denied them every requisite establishment to render their acquirements availing, and most unreasonably expected her armies to reduce the skilfully fortified and well-covered places of the nineteenth century with means inferior to those brought against the exposed and ill-constructed places of the sixteenth and seventeenth centuries." And what was the immediate consequence of this irrational jealousy and niggardly parsimony? Contrary to all ordinary calculation, the fortresses garrisoned by the French in Spain were reduced; but at what a prodigious expenditure of life was this effected? In the several attacks upon Badajoz, two of which, from extrinsic circumstances, proved abortive, a little army was sacrificed; as many men, in short, as would have been sufficient for the consumption of *ten* sieges undertaken with adequate means, and conducted according to the ordinary rules of science. But this is not to be understood as involving any reflection against the military talents of the general or the professional ability of the engineers. General Foy, in his work on the war in the Peninsula, has indeed made such a charge, condemning the mode of attacking fortresses adopted by the British in Spain as unskilful and inefficacious, and bringing it forward as indisputable proof of the low state of military knowledge in our army. But it should be recollected that the adoption of this mode was not a matter of choice, but of necessity; and that if it was in its own nature rash, hazardous, and inefficient, the fact of its having been directed against Ciudad Rodrigo and Badajos with such rapidity of development and certainty of result as to outstrip the calculations of the French marshals, deceive the vigilance of French governors, paralyse the science of the French engineers, and baffle every defensive effort of the French garrisons, is surely no evidence of deficiency in military talent and professional skill. The objections to this mode of attack are insurmountable and decisive; that it succeeded in the instances referred to is merely a proof what British soldiers, even when acting under the greatest disadvantages, are capable of accomplishing. The force of the remarks of Sir J. Jones has not become less by the progress of time, as the present war found us, not indeed so deficient in well-trained sappers as we were at the commencement of the last, but equally so in all the most important elements of modern organization, and, as regards this special branch of the service, not yet determined as to what the field equipment of the engineer establishment ought to be. We have still to learn the importance of that scientific knowledge which would enable the engineer to vary that equipment so as to meet the necessities of the geological structure of each particular country.

Having thus given a general description of the methods of attack, we shall now subjoin, on high authority, a view of what is considered as necessary for the proper defence of fortified places. An order issued by the French minister of war in 1813 contains directions on the subject which are almost universally applicable, and therefore deserve a place here. Every commander is directed to consider his garrison as liable to be unexpectedly attacked, and to pass at once from a state of peace into one of war or siege, either by rebellion, by unlawful assemblies, by the presence of an enemy, by surprise, or by sudden assault; in a word, by unforeseen causes, of which the history of war offers numerous examples. He is therefore ordered, even in time of peace, to fix his plan and arrangement for defence, according to such supposed attacks as may appear most probable, and to determine, for the principal cases which may be likely to occur, the necessary posts, reserves, and movements of the troops, and to take measures to ensure the due and active co-operation of every corps of the garrison. He ought, particularly, to make himself thoroughly acquainted with, *first*, the ground beyond the place which may be within the circle of action, of investment, and of attack; *secondly*, the fortifications of the place, its interior, its buildings, its military edifices or establishments; *thirdly*, the garrison, the means of the place in artillery, in ammunition, and in other stores of every kind; *fourthly*, the population to be subsisted in time of siege, the men capable of bearing arms, the master and journeymen artificers fit to be employed either on the works or in case of fire; and, *fifthly*, the provisions, materials, tools, and other resources which the town itself and surrounding country can furnish, and which it might be necessary to secure in case of siege. In order to enable governors and commanders to comply with these instructions, which are equally clear and precise, the minister proceeds to detail their principal duties, according to the circumstances in which they may find themselves placed; but for these we must refer to the general order itself, which is a masterpiece of its kind, and in all probability emanated directly from Napoleon himself. Its object appears to have

been to inspire a governor with hopes, that by taking proper precautions, and making a full use of means previously provided, the defence might be rendered equal, if not superior, to the attack; and although it is still considered that the idea of attaining such an advantage for the defence is far from being realised, yet the importance of the directions embodied in the order is not on that account diminished, and where they are duly observed, the nature and extent of the resistance must be materially increased.

The protracted and able defence of Sebastopol will doubtless lead many to doubt the accuracy of the opinion thus stated, and to imagine that the Russians have by some new defensive arrangements solved the problem so long under discussion, and again restored to the defence its former superiority over the attack. This idea has indeed so taken possession of the public mind, that already persons have been found ready not only to assert the supposed fact, but also to explain the mode in which the improvement has been effected: whenever Sebastopol shall fall, and as regards the southern defences, the period of such fall seems approaching, this delusion will doubtless be dispelled, and the real merits of the Russian engineers will be found to consist not in the discovery of new principles, but in the skilful application of those principles which, recognised at an early period, have been by degrees matured and enlarged. In estimating the comparative results of the attack and defence of Sebastopol, it must also be remembered that neither can be judged by strict rules, as neither has conformed to such rules. The north side being left open by the impossibility of fully investing the whole line of defences, the south became a detached line of powerful intrenchments, upon which the whole force of an army, not of a garrison, could be directed at will in its defence. In another point, also, the attack has not had its usual advantage, not having been able to use, with the customary effect, the enfilading ricochet fire, as the disposition of the line of works was such as not to offer sufficiently salient points, and therefore to leave so much to be done by direct fire. The unlimited extent of the garrison, being capable of continued renewal from the external army, has permitted the use of detached forts or works which, when backed by a line in rear of them sufficiently strong to resist a *coup-de-main*, constitute one of the most powerful modes of defence. Such a fort or work is the celebrated Malakoff Tower, and the redoubt enveloping it, the type of which may be found in the Lunette of Darçon, of which fig. 39 is a plan. In this lunette,

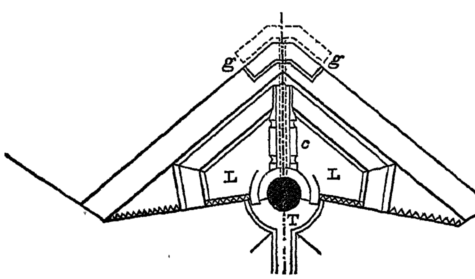

Fig. 39.

intended to be prepared beforehand, T is a powerful tower, LL a lunette, in this case revêted, but which might have been made, as at the Malakoff, a simple earth-work—*c* an underground communication to *gg*, loopholed galleries for flanking the ditches. This little sketch will show the general principle of defence involved in such works, but of course the form must vary in the hands of an able engineer, so as to suit the peculiarities of the ground. At the Malakoff the redoubt has been made circular, but as to principle it is strictly analogous to the lunette. Hereafter, without doubt, the details of this remarkable siege will become the study of military men, but at present it is necessary to select some other example, as there is as yet far too much uncertainty as respects the exact form, construction, and position of the works of Sebastopol to enable an engineer to reason with certainty upon them.

Siege of the citadel of Antwerp.

For the elucidation, then, of the attack, we shall now proceed to give a sketch of the attack on the citadel of Antwerp; first, because this was the most regular and scientific siege which had taken place for many years; and, secondly, because, as a practical operation, an account of it must not only be more interesting, but at the same time more instructive, than any description whatsoever of the formal theoretical plans which are usually drawn in the military schools.

The French army employed to cover and conduct the attack of the citadel of Antwerp, in November and December 1832, was placed under the command of Marshal Gerard, and amounted to 54,000 infantry, 6000 cavalry, and 6450 engineers, artillery, and pontonniers, making a total of 66,450 men, and 14,300 horses, with 144 pieces of siege, and 78 of field artillery. On the 24th of November Marshal Gerard established his head-quarters at the village of Berchem, about 2500 yards from the citadel, and issued orders to commence operations in the evening as soon as it became dark. The garrison of the citadel, under General Baron Chassé, amounted to 4470 men, with 144 pieces of ordnance of all calibres, and abundance of ammunition and stores.

It will be observed here that a garrison of about 5000 men was opposed to the attack of a besieging army thirteen times its strength.

At eight o'clock P.M. on the 29th November the French troops destined for this service consisted of 18 battalions, 900 artillery, and 400 sappers, in all about 17,140 men, assembled at the depôts of intrenching tools. The flank companies of these brigades, supported by twelve eight-pounders and a strong piquet of cavalry, formed the covering party under the direction of General Haxo, by whom and the officers of his department (the engineers) the first parallel and approaches were traced out, whilst General Niègre and the officers of artillery marked the sites of the projected batteries. The first parallel leaned on the covered-way of the right face of Montebello, and extended towards Kiel, its nearest point being about 325, and its farthest 435 yards from the advanced front of the citadel. The distance covered by the first parallel, from right to left, was 1870 yards, and that by the approaches 3750 yards. The communications from the right and centre debouched from the Malines Chaussée, in the village of Berchem, parallel to the road leading from that village to the Harmony and St Laurent; that from the left commenced near to the garden called Heinrich's; whilst a fourth, on the extreme right, sprung from the covered-way of the left flank of Montebello, opposite to the first traverse.

On the second night, from 30th November to 1st December, five approaches were pushed on in front of the first parallel; two in the direction of the capital of the Toledo bastion, two upon that of the Lunette St Laurent, and one, being the fifth, terminating in a place of arms on the extreme left. From the 1st to the 2d December two zigzags were added to the approaches; one from the centre, in the direction of the gorge of St Laurent, and the other on the right, diverging towards the curtain, between the Toledo and Fernando bastions. The badness of the weather sadly incommoded the workmen, and prevented the artillery getting the guns into battery. Between the 2d and 3d December four zigzags were made in front of the approaches on the right and centre, and half a parallel was formed to complete the place of arms constructed on the left during the night of the 30th November. The heads of the zigzags were pushed to within 135 yards of the glacis. The batteries Nos. 1, 2, 3, 4, 5, 6, and 9, with two for mortars

in the rear, were armed, and ready to be unmasked at a moment's notice. The arming of Nos. 7, 8, and 10, on the extreme left, was impeded by the difficulties of the ground. From the 3d to the 4th December, the second parallel was traced and commenced, its right leaning on the foot of the glacis of the counterguard, its centre and right 130 yards distant from the place of arms in the covered-way of the Toledo bastion, and its left towards the right of the covered-way of St Laurent, at 90 yards from the crest, and 15 from the foot of its glacis. The length of the second parallel was 1250 yards, and, together with its approaches from the first parallel, it occupied 3025 yards of ground. By the greatest exertions batteries Nos. 7, 8, and 10 were armed during the night. This completed the armament, and, at 11 A.M. on the 4th, the embrasures were unmasked, and the signal being given, the batteries opened their fire from centre to flanks, and maintained it steadily during the day.

From the 4th to the 5th of December an approach was pushed on from the second parallel, almost in a direct line upon the salient angle of St Laurent, and an entry was made into the covered-way by a return to the left. The garrison discovered this, and opened a sharp fire from the lunette; a lodgment was, however, effected near the spot usually occupied by the first traverse. At this time the garrison suffered much from the fire of the besiegers. From the 5th to the 6th the lodgement made the previous night in the covered-way of the salient place of arms of St Laurent was prolonged as far as the first traverse. But the besieged kept up so vigorous a fire that the French engineers were obliged to renounce the flying and adopt the full sap. The zigzag in the counterguard, being about three feet in width and four in depth, was conducted along the parapet, nearly to the extremity of the right flank, and within 180 yards of the counterscarp of bastions Toledo and Fernando; and two lodgments, blinded with fascines, were made in the parapet for six rampart guns to enfilade the covered-way of the Toledo bastion. In the meantime a steady fire was kept against Kiel, the ravelin in its rear, and the Paciotto bastion. From the 6th to the 7th a battery of 24-pounders near the village of Burcht on the left and Hoboken on the right opened on the gun-boats which flanked the French post at the Melk Huys. It was intended to assault St Laurent this evening; but as the lunette was found to be too well protected by *trous-de-loup*, the project of storm was abandoned, and the regular method of descent, passage, and mine, determined on.

Between the 7th and 8th of December a shell penetrated the blindage of the laboratory, and setting fire to loaded bombs and other combustibles, caused considerable havoc. A battery for six mortars, E, on the right between Nos. 3 and 4, now opened its fire; another, F, also for six mortars, was traced behind the centre of the parallel; and platforms for four mortars were laid down near Montebello. The fire of these batteries was directed on the Toledo bastion and the buildings within it. On the previous day jets of smoke and flame were seen to issue from the Great Barracks, and, in spite of every exertion on the part of the garrison, the whole building soon became involved in a general conflagration, which raged with such fury, that by the evening of the 8th it was entirely consumed.

From the 9th to the 10th of December the operations against St Laurent were renewed with great activity, and the sap advanced to the crotchet of the second traverse, whilst that intended to debouch upon it from its right was likewise pushed on. The principal operation of the night, however, was the opening of the third parallel, 130 yards in advance of the second, its right debouching beyond the Boom Chaussée, from the branch running into the covered-way of the counterguard, and its left uniting with the boyau parallel to the foot of the glacis of St Laurent. At this time the garrison suffered much from the vertical fire of the mortars and howitzers, especially the great mortar, and the new-model eight-inch howitzers. Until the year 1822, the eight-inch howitzer in common use in France measured three feet six inches French, and weighed 1096 lb., or twenty-three times the weight of the loaded projectile, whilst its calibre was equal to a solid shot of 80 lb., and contained 65 ounces of powder. The new-model howitzer is an improvement on the Russian licorne and the Spanish heavy howitzer, perfected by Colonel Paixhans. The raft for the blinded descent into the ditch was brought up to the lodgment, and a second descent *à ciel couvert* was commenced to the left of the first. The third parallel was, at the same time, improved and widened. A little after dusk on the 10th the besieged made a sortie, which was driven in, but not until damage enough had been done to occupy the French all the night of the 10th and morning of the 11th in repairing it. From the 11th to the 12th three rafts were got ready, and placed in the descents to the ditch; they were about twelve feet by eight. At dusk the miners returned to the escarpe, and, in an excavation made the previous night, fixed two petards, which, by their explosion, produced a fissure in the wall; and a serjeant having immediately entered the hole, commenced a gallery under the centre of one of the arches. At 11 A.M. on the 12th the battery mortars, H, on the extreme right of the second parallel, opened their fire, which, combined with that from the others, told severely on the Toledo bastion. The miners still continued their work under the lunette St Laurent, and commenced chambers for three mines. The fourth parallel was widened during the day.

Between the 12th and 13th of December the miners were at work in the chambers under St Laurent, which were not yet completed. On the right the covered-way of the left face of the Toledo bastion was crowned to within sixty-five yards. From the 13th to the 14th, after nearly sixteen nights of open trenches, the arrangements for the assault of St Laurent were completed, and orders were issued to prepare for the storm. Much, a great deal too much, was said of this out-work, defended by little more than a hundred men, one five-and-a-half inch howitzer, two coehorn mortars, and a six-pounder. The mine being reported charged, the blinded descent into the ditch was pierced as soon as it became dark, and everything got ready for the assault. Three storming parties, consisting of the flank companies of the 65th regiment of the line, were posted in readiness, with a column of reserve; and at 5 A.M. on the 14th, every preparation being completed, the match was applied to the saucissons of the mines. After a few moments of suspense, three successive explosions took place, and the escarpe immediately presented a wide and practicable breach. The fascines for crossing the ditch had been injured by the explosions; but after a little delay the storming party entered almost without opposition, and made prisoners one lieutenant and forty-eight rank and file, the others having escaped into the citadel. Thus fell the lunette St Laurent.

After this operations were carried on against the citadel, and at 11 A.M. of the 21st December the battering in breach commenced, and continued for two days. At length, on the 23d, when a practicable breach had been formed, and Marshal Gerard was about to deliver the assault, the garrison surrendered, after as gallant a defence as any recorded in military history, though more remarkable for its passive than its active character. When Marshal Gerard, accompanied by the French princes, entered the fortress, they found General Chassé in a casement in the Alba bastion, which he had occupied during the siege. On their progress from the gate to the governor's quarters, they passed through a scene of desolation and ruin, intermixed with painful and disgusting objects, which baffles all description. The whole, indeed, presented an unparalleled chaos of black

and smouldering destruction; and, with the exception of the principal powder magazine, two or three service magazines, and the hospital, not a building was standing. The terrepleins of the bastions were ploughed into deep ruts by the shells; the gorges were encumbered with heaps of fallen rubbish; and though the casemates and subterranean communications were not perforated, all of them had sustained damage from the incessant explosion of shells, and they emitted an offensive, nay, almost insupportable odour, caused by the number of men who had been crowded into these vaults. Everything was of course said by the victors to console and flatter the vanquished. When Count Gerard took his leave of General Chassé, he observed to the brave veteran, "that it was high time to surrender; that he had gallantly and honourably done his duty, and that he ought not to have held out a day longer." With a fortress reduced to a heap of ruins, a garrison exhausted and extenuated, and a breach sufficiently wide to admit a column formed upon a front of a hundred, it would not have been bravery, but madness, to attempt, under such circumstances, to stand an assault.

The following is a list of the different batteries, with the direction of their fire respectively:—

	No. of Batteries.	24 Pounders.	16 Pounders.	8-inch Howitzers.	10-inch Mortars.	Distance in Yards.	Direction of Fire.
	1	6	...	2	...	535 & 550	Battering the left face of Toledo, and gorge of St Laurent.
Opened on the 4th and 5th December.	2	...	2	2	...	500	Ricochetting the left face of Toledo.
	3	4	...	2	...	640	Battering the left face of the Ravelin.
	4	...	3	2	...	650	Ricochetting left face of the Ravelin.
	5	6	2	1	...	630 & 430	Battering right face of Toledo, and Ricochetting left of Toledo.
	6	...	2	2	...	700	Ricochetting left face of Toledo.
	7	6	2	1	...	380 & 700	Ricochetting left face of St Laurent, and battering right face of Paciotto.
	8	...	3	2	...	465	Ricochetting left face of Ravelin.
	9	...	...	6	...	820	Battering salient angle of Paciotto.
	10	8	...	...	...	650 & 520	Battering left face of Ravelin, and Lunette of Kiel.
	A	...	...	...	10	850	Not armed.
	B	...	...	...	9	1000	Body of the Citadel.
	C	...	...	...	11	1050	....
	D	...	...	...	10	850	....
	...	30	14	20	40	......	....
Between the 8th and 18th.	11	4	...	...	...	500	Battering the right face of Toledo.
	12	...	3	...	...	435	Battering the Batardeau.
	13	...	4	...	...	220 & 275	Battering the left face of Ravelin.
	E	...	...	...	6	500	The body of the Citadel.
	F	...	...	...	6	490	....
	G	...	...	...	6	650	....
	H	...	...	...	6	380	....
	K	...	...	...	8	600	....
	14	6	...	...	..	50	Breaching Battery.
	15	6	...	...	...	350	Counter-battery against the left flank of Fernando.
	16	...	...	...	...	125	Six pierriers on the Ravelin and Toledo.
	L	...	...	...	10	250	Terreplein and rampart of Toledo.

This operation, so instructive in a military point of view, is also remarkable as having occurred in a time of general peace. It would be out of place here to enter into any detail of the complicated series of events and negotiations out of which so singular an occurrence arose: we shall therefore content ourselves with observing, generally, that Great Britain and France, as joint guarantees for the integrity and independence of Belgium, having failed in every attempt to procure the evacuation of Antwerp by means of negotiation, were obliged, by the faith of treaties, to have recourse to force. Hence the siege, politically considered, is to be viewed merely as an ejectment executed against the king of Holland, who had refused to renounce possession, unless compelled to do so.[1]

The French brought against this place 66,450 men, 14,300 horses, and 222 guns of all descriptions; and they lost during the siege 108 killed and 695 wounded, total put *hors de combat* 803. The Dutch had 4937 men in the garrison, of whom they lost 122 killed, 369 wounded, and 70 missing, total 561.

A careful comparison of the details of this siege with the general principles which have been enunciated will enable the reader to recognise the importance of the following maxims.

1. Independently of the great amount of labour to be provided for in the construction of parallels, approaches, and batteries, there will be a daily drain upon the besieger's forces by casualties, so that he can scarcely expect for success unless his original preponderance in numbers has been such as to leave him at the final moment of assault in a condition to attack the diminished garrison with an overwhelming force. In addition, therefore, to a covering army when external relief is threatened or anticipated, the besieging army should be from four to five times the strength of the garrison, or even more, should the nature of the ground, as at Sebastopol, add to the ordinary difficulties of approach. This superiority of force is necessary to give celerity and steadiness to the operations, which would otherwise be tedious and interrupted.

2. A perfect investment is not merely expedient but indispensable. So long as any portion of the enceinte of a fortress is left open or unwatched, the garrison is able to recruit its strength from without, whilst within it is relieved from that moral depression which must, more or less, oppress men when entirely closed up within a narrow space, and exposed, day after day, to fatigue and danger. Under such circumstances there seems to be no natural limit to the power of defence, as fresh supplies of men enable the besieger to go on adding intrenchment within intrenchment, and it is only possible to overcome him by determined, reiterated, and overwhelming assaults. Such *have been* the circumstances of Sebastopol, as the system of attack adopted by the allies has never enabled them to isolate even the southern section of the fortress, the means of communication between the south and north remaining available to this day. Without doubt fresh troops, or rather reliefs, are brought to the south side frequently, and a temporary superiority in numbers on that side given to the defenders over the immediately attacking force. It ought not, therefore, to be a matter of surprise that the progress of the siege is slow, and, to the eye of the general observer, uncertain, because so frequently interrupted.

3. Good and secure lines of communication are most essential, as there ought not to be any cause of interruption when once the ground has been broken and the siege commenced. Neither in the attack nor in the defence should guns be fired idly, or from distances and positions which would render their fire useless; but when the proper distance has been arrived at, battery should succeed battery as the works of approach advance, and no interval for rest or for repairing injuries should be allowed to the besiegers; but how can this object be ensured with roads so heavy and bad as to stop the transport of ammunition and of ordnance?

4. The importance of advanced works was strongly exhibited at the siege of Antwerp, as the whole force of the attack was directed against the advanced lunette St Lau-

[1] The account of the siege given above is abridged from that published in the *United Service Journal*, and which is decidedly the best that has yet appeared.

rent, whilst the defence was good, although under the disadvantage of wanting the collateral defence of the Lunette Montebello (see Plate CCLXII.) In such a case as Sebastopol, the garrison being in fact a small army, such works must afford the best means of an obstinate defence, and, by forcing the besieger to act on the circumference of a larger circle, diminish very much his ordinary advantage of concentration.

Siege of Dantzic.

Having thus given an example of an interior and passive defence, we shall now, in further illustration of the principles already laid down, advert to one of a different if not opposite kind. The siege of Dantzic, whether considered with reference to the magnitude of the operation, the difficulties to be surmounted by the besiegers, or the active and varied character of the defence, was certainly one of the most memorable events in the campaign of 1807. Before the war of 1806 and 1807 the fortifications had been much neglected, because, from the position of the place, no one suspected that it would have to sustain a siege. But when the battles of Iena and Auerstadt had entailed destruction on the Prussian army, and laid open the kingdom, General Manstein, who commanded at Dantzic in the absence of Field-marshal Kalkreuth, the titular governor, had laboured with much activity in improving the exterior works, and particularly in causing them to be strongly pallisaded. It is necessary, therefore, to describe the principal defences at the period when the place was invested by Marshal Lefebvre, at the head of the tenth corps of the grand army, and immediately before the commencement of the trenches on the 1st of April 1807.

The city of Dantzic, traversed by the Moltau, was surrounded with large ditches filled by that river, the waters of which, retained by several sluices, formed, to the eastward, a vast inundation, which, reaching on one side to the suburbs of Ohra and St Halbrecht, and on the other to the dykes of the Vistula, extended about four leagues, and covered two-thirds of the eastern fronts. On the north the Vistula runs about 260 yards from the covered-way, leaving a space between the left bank and the glacis of the place, consisting of an impracticable marsh, intersected by some canals; and at its embouchure, distant nearly three miles, the banks were defended on the right by the fort of Weichsemlunde, and on the left by an intrenched camp in the small island of Neufahrwasser, intended to cover and protect the arrival of such succours as might come from the seaward. The ground adjoining the banks of the Vistula being intersected by canals and covered with marshes, was extremely unfavourable to a besieger, as it rendered it difficult for him to form establishments or raise works of proper solidity, and forced him to extend his quarters, disseminate his troops, and multiply his posts. At the period in question this inconvenience was the more severely felt, because the besieging force was inferior in numbers to that of the garrison, and it required the most vigilant caution to occupy numerous posts without unduly weakening it. The communication between the place and the fort of Weichselmunde was maintained by a series of redoubts constructed on the borders of the Vistula, and particularly by the advantageous position of the isle of Holm, which enabled the besieged so to approximate the fire of the place to that of the fort as only to leave between them an interval of about 1400 yards, and also to communicate with Weichselmunde by the canal of Laack, in spite of batteries which the besiegers might establish at Schellmühl. The French, therefore, could not attempt to throw a bridge over this part of the Vistula until they had made themselves masters of the isle of Holm. On the west two chains of hills, separated by the valley of Schidlitz, covered this part of the enceintc; and the prolongations of these hills were crowned by two forts, that of Bischopsberg and that of Hagelsberg, which, being connected by continuous intrenchments, formed a second enceinte, flanked upon one side by the inundation of the Moltau, and upon the other by the left bank of the Vistula. This new enceinte, though constructed of earth, and without revêtement, was nevertheless secure against insult; and as the covered-way, as well as the foot of the scarps and counterscarps, bristled with strong fraises, which served instead of revêtements, the besiegers had no hope of succeeding by a coup-de-main, and were therefore obliged to proceed by a regular attack. How analogous was this condition of the lines of defence to that of southern Sebastopol after the besiegers had allowed the garrison to recover from their first alarm, and under the guidance of able engineers to place their old works in order, and to supply their deficiencies by new works.

From this description of the defences ot Dantzic, it is easy to perceive that the difficulties attending the operation must have been very great. The principal of these, as stated by General Kirgener,[1] who, until the arrival of General Chasseloup, directed the attack, were, 1st, that Marshal Lefebvre had at first an army inferior to that of Marshal Kalkreuth, and that this army was in a great measure composed of new troops, all those destined for the siege not having then arrived; 2dly, that, owing to the badness of the roads and the inclemency of the season, the artillery experienced the greatest difficulty in bringing up its convoys, whilst the establishment of the batteries was retarded, and a scarcity of ammunition sometimes prevailed; 3dly, that the place requiring an immense circumvallation, which, in fact, could not be completed until after the arrival of reinforcements, the corps of troops which occupied the quarters were extremely weak, and hence could neither furnish a sufficient number of workmen at a time, nor even the number of men necessary for guarding the trenches; and, 4thly, that the besiegers had no good plan of the place, no idea of the depth of the ditches, and that, as the accidents of ground in front of the fortifications were extremely diversified, they could only be reconnoitred in proportion as the works advanced. These circumstances, all of which were reproduced at Sebastopol, the necessity of concentrating the greater part of the troops close to the camp of Neufahrwasser, by which succours arriving by sea might debouch, and, lastly, the advantage which the besieged had been able to preserve of remaining masters of part of the suburbs, determined the chief engineer, after the investment had been effected, to direct the principal attack against the Hagelsberg, and a false one against the Bischopsberg fort. The true point of attack was the long branch of lines in the plain connected with the bastion on the right of the Hagelsberg: "c'était là le défaut de la cuirasse;" but, for the reasons above stated, General Kirgener was induced to direct his approaches against the fort itself.

As the details of this great siege would fill a considerable volume, all that our limits permit us to attempt is merely to indicate the principal occurrences. On the 1st of February 1807 the troops of General Dombrowski began to approach Dantzic, and took up a position at Mewe, upon the left bank of the Vistula. On the 15th General Ménard, commanding the Baden contingent, arrived at the same point, and repulsed a detachment of the garrison of Dantzic, which had advanced from Dirschau to attack him. On the 23d General Dombrowski, having been reinforced,

[1] This officer, the head of the engineer staff, and one of the most distinguished in that branch of the service, fell on the field of battle at Bautzen, where he received his death-wound from the same ball which killed Duroc, the grand marshal of the palace, and the intimate friend of Napoleon.

received orders to attack a large detachment of the enemy which occupied an advantageous position at Dirschau and its environs. The combat here was obstinate and sanguinary; but the Prussians, though intrenched in a church and a churchyard, were dislodged and driven back, chiefly by the Poles, who, exasperated by their long resistance, put to death without mercy all who fell into their hands. After the combat of Dirschau, General Manstein no longer sought to obstruct the distant approaches. The troops destined to form the besieging army now arrived in succession, and the park of artillery began to be formed. On the 12th of March Marshall Lefebvre found himself in a condition to close in on the place; and the troops of the garrison having withdrawn, he distributed his own in the following positions: A battalion of French light infantry at Ohra, a Saxon battalion at St Halbrecht in the Burgerfeld, and two others at Tiefensee and Kemlade; the Poles occupied Schonfeld, Kowald, and Zunkendin; some battalions took post at Wonnenberg, Neukau, Schudelkau, and Sniekau; the Saxon cuirassiers and light horse were stationed at St Halbrecht and Guirsehkens; the 19th regiment of French chasseurs at Burgfeld, and the 23d at Schudelkau; the Baden dragoons and hussars at Wonnenberg, and the Polish lancers at Langenfurt. On the 16th the marshal attacked the village of Stolzenberg, which he carried after a warm resistance, as he did also the suburb of Schidlitz, to which the Prussians had retired; and on the 18th the place was entirely invested, with the exception of the eastern part, which, by the isle of Nehrung, communicated with Königsberg. Field-marshal Kalkreuth now arrived in Dantzic, and assumed the command of the place. The next operation of the besiegers was the attack of the isle of Nehrung, which, after a severe and protracted struggle, was carried in the most gallant manner, and measures immediately taken to secure possession of this important conquest. A bridge was also established on the Vistula, and various works constructed to check the attempts of the enemy either on the side of Dantzic or on that of Pillau. At this time the governor, who, besides the burgher militia, had under his command a garrison of 18,000 men, made a sortie for the purpose of destroying the works already commenced by the besiegers; but the attempt failed, and the Prussian columns were compelled to retreat into the place without having obtained the smallest success upon any point.

As it had been decided that the principal attack should be directed against the fort of Hagelsberg, favoured by two false attacks, the one directed against the intrenched camp at Neufahrwasser, and the other against Bischopsberg, and also by two other secondary attacks on the left bank of the river, ground was broken on the night of the 1st and 2d April, at the distance of 1600 yards from the pallisades. The approaches were pushed forward with the greatest vigour, and on the night of the 11th the second parallel was commenced by means of the flying sap. On the morning of the 12th the marshal ordered the batteries to be armed, which was accordingly done. On the 13th the enemy made a sortie in force, attacked the Saxons with great impetuosity, carried a redoubt constructed upon the mamelon of Hagelsberg, and even penetrated to the head of the trenches; but they were ultimately repulsed, though not without difficulty and loss. By the 23d all the batteries of the first and second parallels, and those of Stolzenberg, were armed, and emplacements were provided for field howitzers, in order to throw shells into all quarters of the city. At daybreak on the 24th the batteries were unmasked, and though the garrison returned the fire with the greatest vivacity, that of the besiegers soon obtained the ascendancy, committing great ravages in the place. Being apprised of this circumstance, Marshal Lefebvre summoned the governor, who replied in a manner worthy of himself. The fire of the mortar and reverse batteries continued during the 25th, in the course of which a new battery was constructed between the low flanks of the Stolzenberg; and the direction of some others changed, in order to batter the right bastion of Bischopsberg, the fire of which had greatly incommoded the French batteries. During the day of the 26th, the fire on both sides was exceedingly animated; but at seven in the evening, that of the garrison suddenly ceased, and a column of 600 Prussian grenadiers, followed by 200 workmen, soon afterwards sallied out of the place. As the sortie had been foreseen, however, preparations were made to repulse it, which was done by a combined attack in front and on both flanks, in consequence of which the whole column was either killed or taken. Meanwhile the works were vigorously pushed forward at all points. The batteries of Stolzenberg were united with the attack on the Bischopsberg; emplacements were prepared for batteries *à ricochet;* at the attack of the Lower Vistula the works were continued, and a tongue of land situated at the extremity of the isle of Holm taken possession of and isolated by means of a cut; whilst at the principal attack the greatest exertions were made to prolong the right of the third parallel, and enlarge the communications. On the 30th April the batteries of the besiegers, augmented by several pieces which had arrived from Warsaw, thundered on the place, in different quarters of which conflagrations now appeared; and the besieged replied by the fire of all the batteries of the front of the attack, directing more than thirty pieces on a redoubt which fired with the greatest effect. But as the fire of the besiegers had made little impression on the exterior fortifications, which were of earth, it was during the first days of May directed chiefly against the palisades, in order to facilitate the assault of the place; and the utmost activity was at the same time evinced in extending, improving, and urging forward the attack; whilst, on the other hand, the garrison showed equal vigour in obstructing the approaches and destroying the works of the besiegers. In fact, notwithstanding the address of the French artillery, that of the garrison still remained effective, because it had not been possible to ricochet the lines of the fortifications, and the resources of the besieged in munitions of all kinds were more considerable than those of the besiegers. In the whole of these circumstances may be seen a rehearsal, as it were, of those of Sebastopol; and the reader will, after a perusal of this description, cease to imagine that the Russians had acquired their knowledge of the use and importance of earth-works from the writings of any author of our day. At Dantzic, as at Sebastopol, a powerful army, guided by a skilful engineer, was enabled to apply the resources of parapet fortification so effectually in defence as to baffle for a long time the efforts of the besiegers.

On the urgent recommendation of General Chasseloup, who had by this time assumed the direction of the attack, it was now decided that the isle of Holm should be assaulted, as the possession of it would enable the besiegers to construct new batteries, to take in reverse the front of the attack. The besieged had spared no pains for the preservation of this important post. In the night of the 6th and 7th of May, however, it was attacked, and, after a desperate resistance, carried; whilst the possession of it was secured by works added to the intrenchments which had just been stormed, and the batteries were turned against the place. At the principal attack the fire of the besiegers had also mastered that of the besieged; and Marshal Lefebvre was preparing to assault the fort of Hagelsberg, when a Russian corps d'armée under the command of General Kamenskoi arrived by sea, and disembarked at the intrenched camp of Neufahrwasser.

At the moment of landing his troops, General Kamenskoi was ignorant of the capture of the isle of Holm, and he was disconcerted to find such an obstacle to his communications with the place. This occasioned delay, which

Fortification.

proved fatal to his enterprise; for had he attacked immediately on landing, it is not improbable that he would have succeeded. It was only on the 15th of May, however, being the fourth day after the disembarkation, that he resolved to make an attempt to succour the besieged city. He began to debouch at four in the morning, and, under cover of a brisk cannonade, formed his force, consisting of from 11,000 to 12,000 men, in four columns of attack. The onset was impetuous, and at first the Russians gained ground, thrice attempting to penetrate the French line; but they were ultimately repulsed at all points, and forced to retreat with great loss to the intrenched camp. Field-marshal Kalkreuth made no attempt to second this attack by means of a general sortie, which would have placed the French between two fires; and by its failure the fate of Dantzic was decided. Such was the issue of the only effort made by the allies to relieve this important fortress.

The works of the besiegers were now pushed forward with redoubled vigour; and in the course of the following day preparations were made for the assault of Hagelsberg. Foreseeing this, Marshal Kalkreuth resolved to make a last effort to destroy the nearest works of the besiegers, and for this purpose ordered a grand sortie, which took place on the evening of the 20th May; but although the Prussians fought with all the fury of despair, they were at length driven back, and pursued even into the ditch of the place. On the 21st the army of siege was reinforced by the arrival of the troops of Marshal Mortier, part of which had remained before Colberg; the marshal himself quickly followed; and orders were immediately issued for the assault of Hagelsberg. Before giving the signal, however, Marshal Lefebvre again summoned the governor of Dantzic, who, having no longer any hope of being succoured, and convinced that the besiegers were in a condition to make themselves masters of the fort of Hagelsberg, showed a disposition to capitulate. A suspension of arms was accordingly agreed to, and this was followed, on the 24th of May, by a capitulation, the principal conditions of which were similar to those which the field-marshal himself had granted to the garrison of Mayence in 1793.[1]

The preceding narrative will in so many respects appear to be an anticipation of the defence of Sebastopol, that it may be well to remark that such as the two defences have been in their beginning and progress so may it be expected that the two sieges will be in their termination—namely, successful for the besiegers. The Prussians and the Russians did everything which bravery and skill could do to save Dantzic, making at the last a bold and gallant attempt to raise the siege by a general attack. Already the Russians have made several grand sorties, and two general attacks of no ordinary magnitude and importance, and it may be expected that before winter they will again endeavour to force the position of the allies; but should they fail, and can it be doubted that they will, how can the Emperor of Russia expect to keep longer from their grasp the just reward of gallantry and perseverance, almost beyond example, for which they have been contending! The hope of the Russians can now only be formed on success in the field, and as that hope becomes with each successive attempt and failure less bright, so must the gloom of disappointment and despair darken until the end shall come, and Sebastopol, although perhaps in ruins, be abandoned to its fate.

BASTIONED SYSTEMS OF THE NETHERLANDS.

The bastioned system of the Italians was soon carried into other countries by their engineers, who were extensively engaged in the service of foreign princes, and it was thus that the celebrated Italian engineer Marchi, coming to Brussels with Margaret of Austria in 1559, appears to have introduced the bastioned system into the Netherlands. It has been shown that in rampart defences, the ordinary earthen scarp adopted in ditches of parapet works had been replaced by a masonry revêtement as a security against surprise, in consequence of which, in old Italian fortresses, lofty revêtements were almost universal; but in a country the soil of which was permeated by water within a few feet of the surface, such a mode of guarding against escalade would have been enormously expensive, and in consequence advantage was taken of the nature of the country to form broad wet ditches round the ramparts, and thus, by securing them from any sudden attack, to render the revêtement unnecessary. The first example of a fortress surrounded by simple earthen ramparts without revêtements is said to be that of Breda, fortified in 1553 by Count Henry of Nassau, and this arrangement required only to be moulded into the bastioned trace to constitute the ancient system of the Netherlands, as described by Freitag in 1630. Freitag made the flanks of his bastions perpendicular to the curtain, the faces 98 yards long, with a flanked angle not exceeding 90°, and the length of the curtain 149 yards.

Freitag had strange notions respecting his profiles, regulating the height and thickness of his ramparts not so much by the resistance they were required to make against artillery as by the *number of sides* of his polygon; but disregarding these vagaries of the systematist, the annexed cut, fig. 40, may be assumed to represent the profile usually adopted by the Dutch engineers, R being the body of the place, F the fausse-braye, D the ditch.

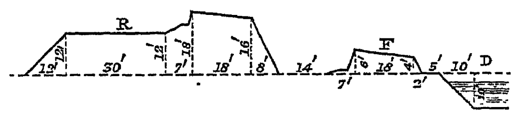

Fig. 40.

It will be observed from the profile, that the main rampart is surrounded by an advanced parapet called a fausse-braye, a work to which reference has been made in a preceding page. By this parapet it was intended to obtain a grazing fire on the ditch, whilst the space between it and the rampart formed a spacious *chemin des rondes* well fitted for the assemblage and movement of troops for defensive purposes; but great as these advantages are, the fausse-braye has dropped into disuse, as it was found scarcely possible to remain in it under a heavy vertical fire, the shells either dropping directly, or rolling down into it from the superior slope of the rampart above. Such *shell traps*, as they are called, are scrupulously avoided by modern engineers, who well know that the improvement of vertical fire will ere long add materially to the difficulties of defence. In the recent bombardment of Sweaborg, a tolerable illustration has been afforded of what may be done by heavy mortars, when the shell has been made a better representative of a mine than it now is. At present a 13-inch shell weighs, when loaded, 200 pounds, and may carry with it, when filled, a charge of 11 lb. of powder, which is ample for breaking the shell and scattering its fragments, but is insufficient for producing great effects as a mine. Should however the projects of Nasmyth and of Mallett be carried into effect, and there can be little doubt that in a modified shape and degree they will, the shell becoming a mine will

[1] Dumas, *Précis des Evenemens Militaires,* tom. xviii., chap. 19, p. 123. *Relation authentique du Siege de Dantzick.* "Les principales conditions de la capitulation furent que la garnison sortirait avec armes et bagages, drapeaux déployés, tambour battant, mèche allumée, avec deux pièces d'artillerie legère et leur caissons attelés de six chevaux, pour être conduite aux avant-postes de l'armée Prussienne à Pillau, en passant par l'île de Nehrung, et en cinq jours de marche. Cette garnison s'engageait à ne pas servir contre l'armée Française pendant un an." (Dumas, *ubi supra.*)

carry with it 1, 2, or 3 cwt. of powder, to destroy not only buildings, but also earthen parapets and ramparts. Passing from the ancient Dutch system as described by Freitag, Marolois, and others, the modern or improved Dutch system of Coehorn deserves especial attention, and is represented in Plate CCLXI., fig. 1, which exhibits his first system.

The great characteristic in this system is the combination of wet and dry ditches, and the use of covering works, or couvre-faces, intended to preserve the body of the place from injury till an advanced period of the siege. These envelopes were first proposed by Dürer, and in like manner the remarkable orillon of Coehorn is a reproduction on a moderate scale of the complicated masonry, or casemated structure of one of his basteien. Coehorn was also well acquainted with the principles enunciated, and the systems proposed by the truly eminent German engineer Speckle, and has manifestly adopted them when applicable to his purpose. The profile, fig. 41, will best enable the student to appreciate the difference between the dry ditches of

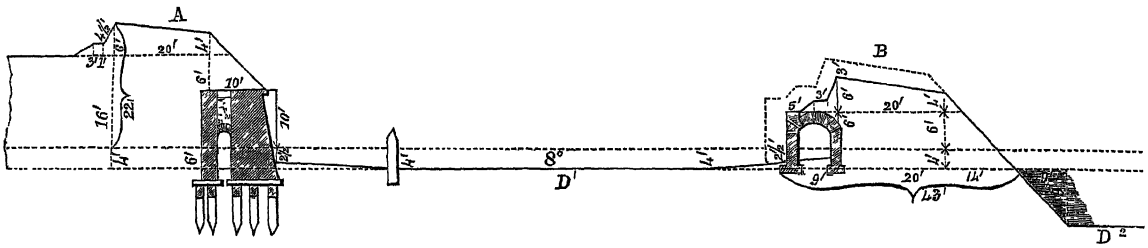

Fig. 41.

Coehorn and the narrow passage afforded by the fausse-braye of the older engineers. A, inner or upper bastion; B, outer or lower bastion; D¹, dry ditch betwixt the two; D², wet ditch.

The profile also exhibits the loop-holed galleries of the counterscarp, by which a reverse musquetry fire may be obtained on the revêted scarp of the inner rampart; a system of defence which has since been very generally adopted, and is most valuable when a secure communication can be kept up between the galleries and the work which they are intended to defend. After the great siege of Corfu by the Turks, and its successful defence by Schullemburg, some Dutch engineers who had been invited to Corfu by him, and had taken part in the defence, were employed in adding detached forts to the old Italian bastioned fronts. In these works, now partly in ruins and partly destroyed, numerous examples of loop-holed galleries and loop-holed traverses may be observed, and they serve to demonstrate, that though Coehorn adopted in his systematic writings his reliefs to the aquatic sites of Holland, he developed principles and means of defence which were equally applicable to other sites and other countries. It has been argued by Bousmard and others, that an opening would be formed by shells through the couvre-face; and that the flanks of the bastions would be thereby exposed to the fire of the counter batteries on the glacis; but it remains yet to be proved whether such an opening through an earthen mass as is here assumed to be made by the horizontal firing of shells could really be thus effected; and the French translator of Zastrow, M. Neuens, captain of artillery, justly remarks, "that if shells fired horizontally into earthen works are so efficacious in destroying them, such shells must be a still more powerful instrument in the hands of the defenders for destroying the besiegers' batteries." If indeed, Zastrow himself observes, we admit with Coehorn and others, that though the besieger may succeed in destroying a few feet of the parapet of the lower or outer face of the bastion, he would in vain by firing horizontal shells into its mass endeavour to lay open the counterscarp galleries, it must be admitted that the besieger on mounting the low face would find himself in a most critical position, as all the defences, both direct and reverse, of the dry ditch, would remain uninjured, and be in full action against him. These dry or inner ditches, as greatly facilitating the war of sorties, and the reverse or counterscarp galleries, are defensive arrangements of great merit, and may, by fitting modification of profile, be adapted to any site; though, of course, the advantage possessed by the dry ditches in such countries as Holland, of not allowing the besieger to excavate in them without coming to water, cannot be expected in other sites, and must be made up for by stone pavements, or other contrivances likely to embarrass the besieger in his excavation. Coehorn assumes the plane of site to be only 4 feet above the level of the water, and the dry ditch of his bastion is at its centre just on the level of the water, so that a passage by sap becomes impossible, as the spade sinks at once into water; but near the scarp and counterscarp the ditches only sink $2\frac{1}{2}$ feet, sloping on each side towards the central portion. The breadth of the dry ditch of the bastion is 98 feet, and that of the wet ditch before the salient 148 feet. All the slopes are at an angle of 45°. The whole breadth or thickness of the couvre-face, measured at the water level, is 52 feet, so as not to allow room for the besiegers' batteries; and its relief of construction only $12\frac{1}{4}$. Ravelin, relief of low face 10 feet, of high face $18\frac{1}{4}$, and the height of its revêtement 8 feet; here also the thickness of the low face would not afford space for forming batteries. The width of the dry ditch is the same as that of the bastion. These few details, together with an examination of the Plate CCLXI., and of the woodcut 41, will enable the student to comprehend the general principles of this great engineer, and it is rather by tracing out the several ideas of a master mind, as exhibited in the *peculiarities* of his plans, than by studying the plans themselves as wholes, that the younger engineer will acquire that store of practical knowledge which will enable him to vary his own projects, so that they may really be the best suited for the ground he is working upon.

Coehorn himself exemplified the observations which have been here made, as he never restricted himself to the rules even of his own system. In fortifying Gröningen he was required to construct works on an eminence which commanded the town, and he adopted a trace which, towards the exterior, exhibited a series of tenailles, the gorges of which were closed by small bastioned fronts constructed of walls which should be easily breached from the main works when the enemy had succeeded in gaining possession of any one of the intervening redans. By this curious combination of the tenaille and bastioned systems, Coehorn gave an undoubted proof of his superiority to the narrow prejudices which prevent many men from adopting the system best suited for the particular place. His example should be followed by every sensible engineer.

BOUSMARD, CARNOT, CHASSELOUP, DUFOUR, HAXO, CHOUMARA.

It would be wrong to dismiss the subject of bastioned systems without at least some more reference to the works of

these distinguished engineers than has been given in tracing the history of this subject. Bousmard makes the faces of his bastions as well as their flanks curvilinear, the former convex, and the latter concave outwards; but though from this arrangement the effect of ricochet fire may be diminished, the difficulty of effectually defending the salient from the flanks is much increased. His great innovation, however, consisted in placing the ravelin and its redoubt in *advance* of the glacis of the body of the place, and forming in front of them a second or advanced covered-way; the object of the arrangement being to close the main ditch entirely, so that the batteries should not fire upon the body of the place through the ditch of the ravelin. The covered-way is made *en cremaillière*, and at each bend there is a sort of redoubt, or casemated traverse, not a simple hollow traverse loop-holed, such as those in the detached works of Corfu. It has been objected to Bousmard's system that his advanced works would be speedily taken by turning the gorges both of the ravelin and its redoubt, but it should be remembered that the interior slope of both is replaced by a loop-holed wall, being the front of an arched gallery running all round, so that the enemy could not remain within exposed to the fire from the galleries, as well as to that from the body of the place. Without advocating the precise form and disposition of the works recommended by Bousmard, it may be reasonably asserted that in every case of a powerful and well appointed garrison the defence will gain by assuming an active character beyond the precincts of the glacis.

It has been already observed that an unmerited indifference has been manifested by many engineers to the merits of Carnot, principally, it may be believed, from his exaggerated estimate of the effects of a vertical fire of small projectiles. Notwithstanding, however, his appeal to imagination rather than to calculation, when he assumed that by substituting 600 wrought iron balls, weighing each $\frac{1}{4}$ lb., for the one shell of 150 lb. he might expect with 6 mortars to project 3600 balls, and to put *hors de combat* 20 men at each discharge, or in 100 discharges 2000, he was right in urging the importance of vertical fire. Carnot, born in 1753, was at an early age a member of the Corps of Engineers, and for his mathematical works elected a member of several learned societies. At the Revolution he was a member of the constituent Assembly; he voted for the death of the king, distinguished himself in the army of the North, and when a member of the committee of public safety, directed in great measure the movements of the French army. In 1795 he was named minister of war, but quickly expelled by Barras and exiled the country; but being recalled, was again, in 1799, appointed minister of war. In 1802 he retired from office, and with that stern integrity which marked his character and made it resemble so much the noble independence of Arago, he voted against the elevation of Napoleon to the imperial dignity. Napoleon did not allow this rigid adherence to principle to disqualify the patriot for employment, and charged him with the defence of Antwerp, as he at a later day named him a peer of France, and confided to him the office of minister of the interior. After the fall of Napoleon he became a member of the provisional government, and was immediately afterwards banished from France. He died at Magdeburg in 1823.

Carnot constructed his scarp without a revêtement but placed a detached loop-holed wall in front of it with a chemin des rondes between, which is one essential feature of his system, the wall being constructed with arched niches in rear so as to shelter the men defending it; the loop-holes are in two rows. He provided arched casemates for mortars on the gorge of his bastion in order to fire upon the capital, and the loop-holed wall of an inner curtain being continued along the retired flanks and in front of these mortar casemates, formed a complete inner retrenchment. Between the tenaille and the ravelin was an elevated earthen cavalier, occupying the position of a redoubt in the ravelin, before the bastion's counterguard; so that the whole of the interior works were masked by these earthen envelopes. There is much ingenuity in these arrangements, and at least as full an appreciation of the value of earthen works as can be found in the writings of any modern writer. Carnot's leading principle however was, that a successful defence must depend on the active operations of the garrison, and that sorties therefore should be frequent and determined as soon as the enemy had approached close to the fortress. For this purpose he removed the revêtement from the counterscarp, and formed it into an easy, or countersloping, glacis to admit of the ready advance of the troops from the ditch upon the head of the besiegers' sap. He supposed that the overwhelming vertical fire of the 10 mortars in the mortar batteries in the gorges of his bastions would prevent the enemy from accumulating large covering parties in the trenches, and that he should therefore be able to fall upon the working parties and successfully delay the progress of the works. It has been shown that Carnot entertained an exaggerated view of the effects to be produced by a peculiar description of vertical fire, but the idea of securing his mortars in casemated buildings is good and has been adopted in one part of the citadel of Ghent; and it is impossible to study his works without being benefited by them. Chasseloup was born in 1754, and died in 1835. He was a lieut.-general, and under Napoleon, Lieut.-General of engineers. Like Bousmard he placed his ravelin in advance of the glacis, and provided it with a small casemated keep, the flanks of which are pierced for two guns each. The tenaille is also provided with casemated flanks, and in front of it is a casemated redoubt or bastionette to supply the place of the ordinary ravelin, and to flank the salient portion of the face of the bastion, the general face being by him bent into two so as to place the salient portion in line with the exterior side of the polygon and thereby secure it from the ricochet fire. Casemated redoubts in the re-entering and salient places of arms, a defensive barrack, and a permanent entrenchment on the bastion are also included in his arrangements. De Sellon (*Memorial de L'Ingénieur Militaire*) observes, "It would indeed be well to force the besieger to pass through two sieges, if the outworks, pushed so far forward, had higher scarps, and were not so easily turned at the gorge; but as the scarp is only 13 feet high, this possibility of attacking the works by the gorge without a previous descent into the ditch, presents such serious inconveniences that it is surprising to observe that Bousmard and Chasseloup should have adopted so defective an arrangement." But notwithstanding this strong condemnation, it is at least doubtful whether such works are not the most suitable for a vigorous defence by a strong garrison, as they would enable the besieged to fall upon the assailants at the most critical moment of their attack with a powerful force; and further, it may be added, that a skilful engineer would know how to throw many difficulties in the way of turning these advanced works, whilst the continuance of the besiegers in them might be rendered both difficult and dangerous in the extreme.

Dufour.

The most remarkable feature in Dufour's modification of the modern system is, that one face of the redoubt in the re-entering place of arms is carried across the ditch, and connected with the coupure of the ravelin, so as completely to close the ditch and cover the face of the bastion from the fire of a battery on the glacis of the salient of the ravelin. Dufour also raised the salient of the ravelin into a high cavalier, so as to secure the faces from ricochet; and he proposes that the cavalier shall be formed of gravel or small stones, so that the fire from the body of the place may cause the enemy, when he has in part destroyed it, and is

Fortification.

attempting to form a lodgment, great damage by scattering about these natural missiles.

Noizet.

General Noizet has been already mentioned in connection with the modern system, his modification of which is now the normal system adopted at all the French military schools. Not adopting Dufour's mode of closing the ditch of the ravelin by carrying across it one face of the redoubt of the re-entering place of arms, he effected this object by placing a massive mask between the coupure of the ravelin and the re-entering place of arms, from the inner scarp of which it is separated by a passage. The counterscarp of the bastion is carried continuously along the inner edge of the mask, whilst in front of it is a ditch which separates it from a demi-caponnière forming its counterscarp and covered-way, and a glacis sloping down the ravelin of the ditch. The mask, the lunette redoubt in the ravelin, and the redoubt in the re-entering place of arms, form a combined series of works of great efficiency for defence, and which completely cover all but the salient portion of the face of the bastion. The flank of the bastion, as before observed, forms an angle of 80° with the line of defence, and the advantage taken of this in the citadel of Ghent in forming a most powerful intrenchment in the bastion, with a curtain as long as that of the main front, has also been pointed out.

Haxo.

General Haxo was one of the most able engineers of modern times. Under Napoleon he distinguished himself at the sieges of Lerida, Mequinenza, and Tarragona. On the restoration he was appointed president of the engineer committee, and directed the construction of the fortifications of Belfort, Sedan, Grenoble, and l'Ecluse. He directed the operations of the siege of Antwerp, and died in 1838. Haxo did not publish his scheme of defence, nor did he reproduce it as a whole in the works he constructed; doubtless considering, as has been so frequently urged, that systems, so called, can only be looked upon as the exhibition of great principles, not as a rigid rule for their application. His ravelin is made very prominent, and the salient is formed into a traverse, or mask, casemated and armed with artillery. Within the ravelin there is a redoubt, and within that a casemated caponnière or bastionette. The ditch of the ravelin is closed by continuing the counterscarp across it with a glacis slope into the ravelin ditch, and by this arrangement the ditch of the redoubt in the ravelin is also closed. The counterguards, the higher and the lower bastions, form almost three lines of defence, of which two, the outer and inner, are powerfully armed with artillery. The peculiar characteristic of the system is, that the parapet is thrown back, and made in its trace independent of the scarp, so that, whilst the latter retains the usual straight line, the parapet is broken into several portions not in the same line, and thus secured from the effects of ricochet—an arrangement of very great merit. Haxo is probably better known to English engineers as the inventor of casemated batteries *à l'Haxo* than from his merits as an engineer, great as they manifestly were. These batteries are formed *in* the parapet, and though arched over with masonry are covered with earth. They are open in the rear to the terreplein, and the openings in front for the guns are continued into embrasures formed in an extension of the parapet at these points beyond its ordinary retired position in Haxo's system. These batteries are thus secured from the effects of the enemy's fire, and when the embrasures are masked are equally hidden from his view, so that they may at any moment suddenly open a powerful and unexpected fire upon the besiegers. Being open in the rear, and connected together by arched openings between every pair, the circulation of air is sufficient to do away with the inconvenience from smoke, so generally complained of in casemated batteries. The batteries *à l'Haxo* have been used at Grenoble and Lyons, and in the forts of Loyasse and Sainte-Foy.

Choumara.

The work of the commandant of engineers, M. Choumara, entitled *Memoirs sur la Fortification*, was published in 1847. In this work he maintains the principle, that the direction of the parapet should be independent of that of the scarp, the latter being formed in straight lines, and considered permanent during the siege, whilst the former may be broken into several lines, and may be modified during the siege so as to facilitate the defence in any direction. Haxo had in his lessons or studies pointed out the importance of this principle; but Choumara was the the first to advocate it in print, though it should be observed that the castle of Naples exhibits an early example of the reverse operation, a new scarp having been built in front of the ancient round-tower forts, so as to change them at the *base only* into bastions, whilst the upper portion of the towers became retired and independent parapets. Choumara, not relying on the bent trace of his retired parapet as a security from ricochet, proposed a traverse in the capital of his bastion, placed outside of the retired parapet, and 33 yards in length. This traverse, made 26 feet high and 78 feet wide at its base, would occupy less than two-thirds of the space of the twelve ordinary traverses required to secure from enfilade the faces of Choumara's bastions 164 yards in length, whilst it would cover not only the bastions but also the flanks. In addition, however, to the traverse or mask in the capital, Choumara proposed high traverses, formed parallel to the flanks, at about 22 yards from the salients, which would not only secure the faces from enfilade, but would form secure or interior flanks, as cavalier flanks commanding and firing over those in front. By making the cavalier flanks 98 yards long, and casemating them *à l'Haxo*, 15 guns might be placed in each, and the covered-way of the bastion attacked would be commanded by 30 guns in addition to those of the ordinary flanks, whilst the traverse of the capital would secure the flank cavaliers from ricochet. Any one who reads and studies these simple and yet effective arrangements will not, it is hoped, longer imagine that the importance of earthen works in their proper place had been overlooked by modern engineers, even though they had learnt to value the beautiful and scientific arrangements of their predecessors. The last and most remarkable suggestion of Choumara is another illustration of the same remark, as he proposes to widen his ditch to about 50 yards, and leaving a passage of communication of 16 yards round the base of the scarp, to form an interior glacis, sloping up from the base of the counterscarp towards the summit of the scarp, and having a base of 34 yards wide, thus constituting a continuous mask round the whole escarp. In respect to countermines, Choumara proposes to replace the great galleries, which are usually made 6 feet high and 3 feet wide, and which are, as it were, the great arteries of a system of mines, by large vaulted galleries from 16 to 20 feet wide, pierced through the counterscarp, and continued as far as the third parallel. Six of these galleries were to be formed in each front, being placed about 55 yards apart, and connected together by minor transverse galleries or branches. Galleries of this magnitude would, in time of peace, be useful as stores, and in time of war would greatly facilitate the operations of the miner. The subject of military mining is so extensive in itself, that it must be deferred to a future article on the subject; but it may be here stated, that this subterranean warfare exercises great ingenuity, and requires great skill both on the part of the besieged and the besieger. The besieged has had the advantage of forming the main galleries of his countermines beforehand, but in spite of this a war of mines must generally be in favour of a besieger, since every explosion of the mines of the besieged, however partially destructive it may have proved to the immediate assailants, must destroy some portion of the works of defence, whilst each one of the besieger's mines must operate in favour of the attack alone. Starting,

however, with this principle, that a fortress, except in some situation which renders regular attack impossible, must ultimately fall, the real object of defence is to occupy the enemy for a sufficient time to suit the purposes for which it was constructed, and in this view of the case the destruction of the battery or of the lodgement of a besieger might materially protract the resistance of the intrenchment formed in a bastion, and thus enable the besieger to maintain his ground so much the longer. The most simple form of mine, and that which may be most readily applied as an obstacle in the way of the assailant, is the fougasse. It consists of a chamber placed at the bottom of a simple pit about 12 feet deep, so as to dispense with the labour of forming a gallery. The charge is placed in a wooden box, and both the charge and size of the box may be thus estimated. When the line of least resistance, or shortest line drawn from the centre of the charge to the surface of the earth, which in this case is the depth of the pit, is 10 feet, a charge of 100 lb. will produce an *entonnoir* or excavation, the radius of which is equal to the line of least resistance, and it has been ascertained that the volume of the excavation varies with the charge, the line of resistance and the resisting medium being the same, and that the volume varies also as the cubes of the lines of least resistance; hence, therefore, if W represent the weight of the charge, B the bulk of the *entonnoir* corresponding to 100 lb. of powder and a line of resistance equal to 10 feet, and b that of the entonnoir corresponding to the charge W and the line of least resistance R, we have $100 : W :: B : b$; but as $B : b :: 10^3 : R^3$, we have $100 : W :: 10^3 : R^3$, and $W = \frac{R^3}{10}$. Now let S = side of cubical box to contain the charge—55 lb. of powder thrown loosely in filling one cubic foot, and $S = \sqrt[3]{\frac{R^3}{10 \times 55}} = 0{\cdot}122\ R$, or nearly $\frac{1}{8}$ R in feet. The pits for fougasses vary generally from 8 to 12 feet in depth, and from 3 to 4 feet in width, being made square, and either secured by being revetted with planks or not, as the earth is or is not firm enough to support itself; and for this latter purpose gabions may be used made of different diameters, so that one may be slipped through the others which have been previously fixed. The box for the powder is well tarred, and when intended to be left in the ground for some time, it may be covered with tarred canvas and then put into another box, also tarred both inside and out. The charge is ignited by a saucisson or linen tube about an inch in diameter, filled with powder, and either laid in a wooden case well tarred, or suspended in it. The saucisson and its wooden case, or other covering, whatever it may be, should be sunk some feet in the earth in conveying it from the charge and pit to the place from which it is to be ignited, in order to secure it from accidents as well as from the enemy's observation (see woodcut, fig. 41). In the figure is also represented the mode in which the fire is applied by what may be called the fire-box, the end of the trough and powder-hose being introduced into it. As the object of military mines requires *immediate* explosion, it is manifest that the firing must be effected by some contrivance for producing instantaneous ignition to be really effective, but this may now be done in so many ways independently of voltaic action—by the use, for example, of friction and detonating tubes—that it would be useless to detail them. It is true that experience has shown how little real injury the explosion of fougasses can do to an assailant; but, as the moral effect of the belief of their existence is a certain degree of hesitation or irresolution, often greater than that produced by actual casualties from musketry fire, the mine must still be considered useful to defence as an obstacle in the way of the assailant. Loaded shells packed in a case may be substituted for the ordinary charge, the case being formed with a partition, and the fuses of the shells placed on the lower portion of the case, passing through holes in the partition, so as to be brought into connection with the saucisson or firing-hose in the upper portion of the case. Another form is the stone fougasse, which is probably the most effectual of all. It is constructed thus: a conical pit is made in the earth about 5 or 6 feet deep, the axis being directed towards the enemy at an angle of 45° with the plane of construction, and at the bottom a charge of 50 lb. of powder is placed in a well-tarred box. Over the box, and perpendicularly to the axis of the cone, is fixed a lid, on which as a platform are packed either stones or broken bricks, which, on explosion, are scattered over a space of about 60 by 70 yards. It should be laid down as a rule that means for discharging mines ought to be provided within the fortress, either by using the voltaic battery for the purpose, or by preparing openings in the works through which the powder-hose may be carried.

The last great modification proposed by Choumara is the extension of the exterior side, and this can no longer be a matter of doubtful expediency when the effective range of the rifled musket has become equal to that of smaller ordnance. The length of the line of defence may now be safely and advantageously fixed at 400 yards, so that musketry and artillery may co-operate together efficiently. Chasseloup had, indeed, also proposed to make his exterior side about 700 yards long; and he was not a mere speculative engineer, as he had fortified with great skill under the orders of Napoleon, Alessandria in Piedmont; but it must be borne in mind that no greater distance should be allowed for musketry than is compatible with distinct vision and a correct appreciation of distance, and further, that the men intended to use the rifle in a fortress ought to be well trained for that object, as the loose fire of untrained men would probably be little better with the rifle than with an ordinary musket.

CONCLUSION.—GERMAN SYSTEMS OF DEFENCE.

After having traced the history of bastioned defence to the high state of perfection it has now attained, a brief summary of other systems seems necessary to complete the subject. It has been shown that no sooner had the Italians invented the bastioned system of defence, than it found in every country persons who devoted themselves to what they considered the improvement of its details: France had its Errard, its Pagan, and its Vauban; the Netherlands its Freitag and its Coehorn; Germany its Speckle; and it may be asserted that the last-named was at least equal to any of the others. Germany, however, though it might have justly prided itself on Speckle, has gone back to Dürer, and adopted from him the other system of flanking defence, which depends on the use of casemated galleries, and of caponnières or casemated works thrown across the ditches. Yet though this has become the result, it is remarkable that the Germans have taken their systems, as exhibited in the most remarkable of their modern works, from a French officer—the celebrated Marc René, Marquis de Montalembert, who was born in 1713, and commenced his military service as an officer of dragoons in 1731. He was a person of very varied acquirements, and became when still a youth a member of the Academy of Sciences of Paris, but fortification and the art of war were his favourite studies. In 1776 he published his celebrated work entitled "*Perpendicular Fortification, or an Essay on Several Methods of Fortifying a straight line, a triangle, a square, and all polygons of any number of sides, giving to their defence a perpendicular direction. Also, Methods of Improving Existing Defences, and rendering them much stronger. Also, Redoubts, Forts, and Field Intrenchments, of a New Construction,*" a colossal work, embracing 11 quarto volumes, enriched with 165 large plates, and which must be considered the source from

which all the modern *inventions* in this branch of fortification have been derived. In referring back to earlier German writers, it appears that Rimpler in 1673 proposed a system which is a combination of bastions with tenailles, and Landsberg one in 1712 which is purely a tenaille system; but both of these adhere to earthen ramparts and parapets, either with revêtements in the first, or without them in the second, and their systems may be therefore considered an extension of the trace of parapet fortification to rampart fortification. But Montalembert, in his tenaille system, replaces the simple revêtement at the re-entering angles with casemated works in two stages, thus affording both direct artillery and musketry for the defence of the ditch and faces of the redans, the remaining portion of the trace being occupied by an earthen couvre-face work, with a detached loop-holed gallery in front of it, being evidently the prototype of Carnot's detatched revêtement. The re-entering casemates were calculated to hold 24 guns in two tiers. Behind the couvre-face was the body of the place of the redan, being also fronted by a casemated gallery, and separated from the couvre-face by an inner wet-ditch. In this system, then, the defence by musketry as well as by artillery is at two levels, the one at a moderate height above the bottom of the ditch, and not, as in the old Italian systems, at the high level of the crest of the parapet. At the gorge of each redan is placed a formidable casemated tower; whilst in front of the main ditch there is a general couvre-face provided also with casemated galleries, a second or advanced ditch, places of arms in front of the re-entering angles, a covered-way, and a glacis.

The polygonal system may be considered as springing directly from Dürer's work of the same name, only in this case the simple earthen ramparts of Dürer are exchanged for a combination of casemated towers, casemated galleries, earthen couvre-faces; and the caponnières, which, as in Dürer's, flank the ditches, assume the more artistic form of bastionettes. In Dürer's polygon the sides were straight or unbroken, but in Montalembert's the centre was thrown back and formed into an Italian bastioned trace, the faces flanking the faces of the caponnière, and again, therefore, exemplifying the difficulty of ensuring perfect flanking defence by any other trace. In forts which formed a triangle or square Montalembert was rich in resources, though the massive casemated tower, casemated galleries, and earthen couvre-faces may be considered the essential elements of all. In France, the views of Montalembert have never been received with enthusiasm, though Cherbourg is fortified in conformity to them, and it was even alleged that the corps du genie was indisposed to receive instruction from an officer of another arm; but it is more reasonable to suppose that the cherished name of Vauban has induced its officers rather to direct their attention to the improvement of the bastioned system, which they have certainly carried to perfection, than to the development of one depending on such different principles. In Germany, on the contrary, Speckle is less known than Vauban, and though probably a thought of Dürer may not enter into the question, Montalembert's systems, founded upon some of his principles, have been readily adopted, and may be studied in the works of defence of Coblentz. In all such works masonry defences or casemated buildings assume a character of the highest importance, but it should not be forgotten that no masonry can resist the force of a *concentrated* fire of heavy guns, and can only be considered safe when protected by earthen masks or couvre-faces. The Maximilian towers of the defences of Lintz, therefore, are not now approved by modern engineers, and the Russians have exhibited their distrust of the most formidable looking masonry defences, even when opposed to ships, by closing the harbour of Sebastopol against approach by sinking a large portion of their own fleet; and this is not to be wondered at, when it is remembered, that to bring the guns forward in order to give them a necessary latitude of fire within casemated batteries, the walls must be much cut into, and therefore greatly weakened. This great defect of masonry defences is well known to engineers, in addition to the further evils of smoke in close casemates, but it is presumed that no one who has read this essay will now imagine that it was necessary to wait to the present epoch for this knowledge, as the earthen mask or couvre-face has been shown to have been applied at a very remote period of the history of the science. In the earliest periods of the Italian fortification, the necessity of increasing the active power of the flanks beyond that which could be obtained by their length alone was strongly felt, and in consequence retired flanks, one rising above the other, were adopted, as well as casemated flanks which admitted of two or more tiers of guns, thus, as in Montalembert's system, obtaining a greater number of guns by extending the battery vertically. At first sight this appears a natural mode of gaining a superiority over the attack, in which the batteries can only be extended laterally, but in practice the retired flanks were soon found to be untenable, as those in front were complete shell-traps, and the casements were practically useless from the difficulty of clearing them from smoke. The systems of Montalembert partake of the same defects; and however imposing the appearance of several successive tiers of guns may be, it should be remembered, that, if covered by the mask, they can only be partially used when the enemy is at a considerable distance, and that the tiers exposed to view may be easily destroyed by the guns of attack of the calibres now used at 500 yards. Several writers have proposed systems based upon similar principles to those of Montalembert, but it is perhaps sufficient here to mention the work of Don Jose Herrera Garcia (*Teoria Analytica de la Fortificacion Permanente*), as it unquestionably affords the most remarkable development of the tower system of defence. Garcia proposes several successive lines of massive casemated buildings or towers, of an egg-shape, connected together with what may be called casemated curtains. The towers are surmounted by a parapet, which at the ends next the enemy is broken into a series of smaller curves, and is retired or independent of the exterior wall or scarp. As each of these towers is defensible of itself, the work of forcing a way through three lines of them would undoubtedly be most formidable, but of course the expense of such a system would be enormous.

The system of the Swedish general Virgin belongs to the bastioned systems, but it is mentioned here in contrast to Garcia's, as it disperses in the defences separate bastioned forts of a form somewhat approaching to Rimpler's, and covered by outworks so arranged as to secure the inner works from injury until the enemy has effected his lodgement upon them. These forts were to be surrounded on all sides by ditches, and connected together by secure communications. Ingenious as Virgin's system is, it is manifest that though the loss of one fort would not ensure the fall of the others, it would at least render all the interior space inclosed by the line of forts untenable, and place the town, the arsenal, or other public buildings, at the mercy of the besiegers. This may be said of all detached forts, and it must be again laid down as a maxim, that the ultimate value of such forts, as a means of securing some important object, depends on an inner line of defence of a nature to resist any sudden attack or *coup-de-main;* and this principle should be applied to the defences of such places as Portsmouth and Gosport. Detached forts will be, for such a purpose, more effectual than a simple continuous line, as they may be so placed as to keep the enemy at a proper distance, but they will cease to be of use if an enemy can safely pass them and attack a defective interior line behind, incapable of resisting a *coup-de-main.*

Zastrow, in commenting on the systems of Montalembert, remarks, "the appearance of the system of Montalembert has overthrown all which was before considered good and excellent," and the Germans have acted upon that dictum both in their teaching and in their constructions; but now another writer, who, like the early Italian writers on the art of fortification, is an architect by profession, has endeavoured to replace the massive masonry works of Dürer and Montalembert by equally massive earthen defences. In his system is seen a ditch 50 feet deep and from 150 to 300 feet wide to afford earth for a rampart rising at its inner crest to about 60 feet above the plane of construction, and formed into five concentric parapets, being in fact so many fausse-brayes of the old Dutch system. Such was the system when first proposed to the consideration of the corps of engineers, but now, is it too much to say, partly from the remarks then offered upon it, the exterior circle has been shaped into something very like a bastioned trace, so as to flank the ditches by strong narrow bastions or caponnières, thus introducing the German or Dürer principle in combination with the Italian one. The Haxo principle of casemated batteries appears to be that adopted by Mr Ferguson for his guns, and he imagines that he can thus gain the increased fire of several tiers of guns without the inconveniences consequent upon casemated masonry buildings. It is to be regretted that Mr Ferguson should have charged upon the corps of engineers illiberality, because they hesitated to publish in their professional papers a scheme of defence not even then matured by its author, and not supported by any estimate of its cost; and further, because they have pointed out that the caponnières or the lower flank of his bastion built up against the earthen scarp would be destroyed with ease at a considerable distance, and the main ditch, when dry, left without defence, as the lofty battery alone could afford it no protection.

So far from engineer officers rejecting improvement, from whatever source it may come, it may be asserted with justice, that they are quite ready to admit the ingenuity of Mr Ferguson, though they may not be prepared to admit that a multiple general intrenchment, without interior flanking defence, would really render a fortress impregnable; and they believe that ere long an accurate description of the works of Sebastopol will prove that the Russians could not have derived their ideas of defence from works which, like those of Mr Ferguson, require ditches of enormous depth, and ramparts of vast height, the work of great time and cost.

It has been well stated by the French translator of Zastrow, that the reduction of a place may be considered as a certain amount of work to be performed, the magnitude of which depends on various elements, amongst which the disposition and nature of the works constitute the most important; and that the attack has to perform this work in a certain time, and with certain means, amongst which the principal elements are the quantity of heavy artillery, and, it may be added, the nature of the ground over which the approaches must be carried. When, therefore, it is said that a work fortified on Vauban's first system would fall on the twenty-eighth day,—on Cormontaigne's, with a cavalier intrenchment in the bastion, on the thirty-first,—it must be remembered that this implies the possibility of steadily advancing the approaches over a soil easily worked by the sapper; but should the ground be rocky, and every inch require to be gained by hard and incessant toil, protracting the time during which the sapper is uncovered, and therefore greatly adding to the daily losses of the trenches, these periods may readily be extended to twice or three times the ordinary length. Southern Sebastopol, for example, has now fallen—the intelligence having arrived whilst these last few pages have been passing through the press—and it has cost a year to obtain this signal triumph over an enemy who has exhibited in its defence the highest qualities of military skill and bravery. In this remarkable siege the assailants have laboured under every disadvantage; they have toiled over ground most difficult to sap, and they have been unable to shut off from the enemy, by a perfect investment, those supplies of stores and men which have changed a garrison into an army, and enabled the defenders to keep up to the last that war of sorties and of intrenchments which was so strongly advocated by Carnot. When at length the Russians yielded up the prize, interior intrenchments were yet existing sufficient to check the progress for a time even of victorious soldiers; but the enemy feeling, that, commanded by the Malakoff, these intrenchments must have fallen before another day's attack, and that their retreat would have been then cut off, abandoned them, and thus again confirmed the experience of more than 150 years, that the attack, when conducted with skill and bravery by an army of sufficient strength, must finally prevail. (J. E. P.)

FORTIFIED ISLAND, an island in the Indian Seas, lying off the coast of Canara, about a mile from the land, a little way north from the entrance to Lake Onore. The island abounds in cocoa-nut, palm, and plantain trees, and has plenty of fresh water. It produces the best kind of cari, which is used by the natives in painting their houses. Its name is derived from its fortifications, which were greatly strengthened by Tippoo Saib, from whom it was taken in 1792 by three British frigates. It is upwards of a mile in circuit. Long. 74. 27. E.; Lat. 14. 16. N.

FORTITUDE, a virtue or quality of the mind, which is generally considered to be the same as courage, though in a more accurate sense the one may be distinguished from the other. Courage may be a virtue or a vice, according to circumstances; fortitude is always a virtue. We speak of desperate courage, but not of desperate fortitude. A contempt or neglect of danger, without regard to consequences, may be called *courage;* and this some brutes possess as well as man. In them it is chiefly the effect of natural instinct; in man it depends partly on habit and partly on strength of nerve. But fortitude being the virtue of a rational and considerate mind, is founded on a sense of honour and a regard to duty.

This virtue takes different names, according as it acts in opposition to different kinds of evil; but some of these are applied with considerable latitude. With respect to danger in general, fortitude may be termed *intrepidity;* with respect to the dangers of war, *valour;* with respect to pain of body or distress of mind, *patience;* with respect to labour, *activity;* with respect to injury, *forbearance;* with respect to our condition in general, *magnanimity.*

The motives to fortitude are many and powerful. This virtue tends greatly to the happiness of the individual, by giving composure and presence of mind, and keeping the other passions in due subordination. To public good it is essential; for without it the independence and liberty of nations would be impossible. It gives to character that elevation which poets, orators, and historians have in all ages rejoiced to celebrate. Nothing so effectually inspires it as rational piety; the fear of God is the best security against every other fear. A true estimate of human life, particularly its shortness and uncertainty, together with the numberless evils and temptations to which, by a long continuance in this world, we must unavoidably be exposed, ought by no means to discourage or throw any gloom on our future prospects, but should teach us that many things

are more formidable than death, and that nothing is lost, but much gained, when, by the appointment of Providence, a well-spent life is brought to a conclusion.

FORTROSE, a royal and parliamentary burgh of Scotland, county of Ross, situated on the N. side of the Moray Firth, nearly opposite Fort-George, from which it is 2½ miles distant, and with which it has regular ferry communication. It was made an episcopal see in the 12th century by David I., but only a small portion of the cathedral now remains. It has a handsome episcopal chapel and academy, and a good harbour, with a depth of 14 feet water at high tide. The parish church is at Rosemarkie, about a mile eastward. Sir James Mackintosh received his early education here. Fortrose unites with Inverness, Forres, and Nairn in returning one member to parliament. Pop. of burgh, which includes Rosemarkie (1851), 1148.

FORTUNA, in *Ancient Mythology*, the goddess of fortune, was worshipped with especial honours in various parts of Italy. Her name does not occur in the earlier Greek authors, who refer the chances of life to the will of Jupiter and the decrees of the Fates. The worship of this goddess seems to have been common in Italy at a very early period. Before the Roman era, the Etruscans (among whom she was known by the name of Nursia) had erected a temple in her honour at Volsinii, and the Latins at Præneste. But the most splendid of all her temples was that at Antium, which Horace has celebrated in his ode beginning—

O Diva, gratum quæ regis Antium,

and of which the *sortes* or oracular responses were very celebrated. Fortuna was sometimes represented as blind, with winged feet, resting on a wheel, at others with a sun and crescent moon on her head. The Romans had a tradition, that when this goddess entered their city she laid aside her wings and sandals, indicating by this means that she intended to remain there for ever. Fortuna is mentioned by Roman writers with a great variety of epithets attached to her name, such as *publica, privata, muliebris, virilis,* &c. &c. At Rome alone the number of her temples amounted to twenty-six.

FORTUNATÆ INSULÆ, the name by which the Canary Islands were known to the ancients. The Carthaginians were no doubt acquainted with these islands at an early period; but it was the selfish nature of their policy to confine such knowledge to themselves, for the sake of the commercial advantages to be derived from it. It was not, therefore, till the fall of Carthage that the Greeks and Romans acquired any accurate information respecting the islands on the west coast of Libya. Statius Sebosus, the friend of Lutatius Catulus, consul 242 B.C., who flourished in the time of the Cimbrian war, could not have been the first who made the discovery, though he was probably the first who gave a description of them to the public. Of this account we possess only a few notices by Pliny, who seems to have derived no information from any other quarter. Yet there must have been considerable intercourse with these islands, as we find that Sertorius, when flying before the superior force of the party of Sylla, was so charmed with the account of them he received from some sailors, that he was strongly tempted to take refuge there. The name seems at first to have been restricted to two, Convallis, the island of *Teneriffe*, and Planaria, now *Canaria*, from which the Canary Islands derive their name. Ptolemy extends the name to six islands. (Strab. i. 3; Plin. vi. 32; Plut. *Sert.* 9; see Miñano, *Diccionario Geografico*, &c., Madrid, 1826.)

FORUM, in *Roman Antiquity*, signified originally the open space in front of any public building, and was afterwards applied to the central square in the ancient Roman cities where public business was transacted, and where in the early ages of Rome causes were tried. The forum of the Romans corresponded to the agora of the Greeks, being commonly oblong rather that perfectly square in form, and was surrounded with temples, public buildings, and porticos. The Roman fora were of two kinds, "civilia" and "venalia;" the former set apart for meetings of the people and the administration of justice, and the latter for purposes of trade. The city of Rome itself contained nineteen important fora—the forum Antonini, Archemorium, Argentarium, Augusti, Boarium, Cæsaris, Cupidinis, Nervæ, Olitorium, Piscarium, Piscatorium, Pistorium, Romanum, Sallustii, Suarium, Trajani, Transitorium, and Vespasiani. Of these the forum Romanum, Nervæ, Trajani, Boarium, and Piscatorium still present many interesting remains of the magnificent edifices with which they were once adorned. By far the most important of the ancient fora was the Forum Romanum, which was for a long time the only one of its kind, and was at first known as *the* forum. In later times, when their number was greatly increased, it was distinguished from the others by the epithets of *vetus* or *magnum.* It was seven "jugera" or acres in extent, and was situated in the low ground between the Palatine and Capitoline hills, not very far from the Tiber; but it does not seem possible now to fix its exact limits. It was surrounded on every side by the most splendid buildings of the ancient city—temples, basilicæ, triumphal arches. It contained also many statues of illustrious Romans, and the *rostra* or stage from which the people were addressed, so called from its being adorned with the beaks of ships taken from the Antiates in the early wars of that people with the Romans. The forum, in its widest sense, appears to have comprised the comitium (or place of assembly for the curiæ), which was separated from the forum (in its narrower sense the place of meeting of the comitia tributa) by the rostra. Originally, orators, when addressing the people from the rostra, looked towards the comitium and the curia; but the younger Gracchus got a law passed compelling them to face the forum, and thus acknowledge the sovereignty of the people. In the comitium or upper part of the forum the laws of the Twelve Tables were exposed for public inspection, and the Fasti were afterwards exhibited there on white tables that the citizens might know on what days it was lawful to transact legal business. In 308 B.C. the forum was adorned with the gilt shields taken from the Samnites, and these trophies of Roman valour were afterwards annually exhibited there during the Ludi Romani. One of the most interesting ornaments in the forum was the Columna Rostrata, on which were hung the beaks of the Carthaginian ships taken by the consul Duilius in the first Punic war. Besides the forum Romanum there were two other *fora* judiciaria at Rome, one of them built by Julius Cæsar, and the other by Augustus, to provide for the great increase of public business during their supremacy. None of the other fora were at all to be compared either in size or splendour with these three. A beautiful restored view of the Forum Romanum was designed by Mr C. R. Cockerell, of which a reduced plan was published in the "Pompeii" of the Society for the Diffusion of Useful Knowledge.

FOSCARI, FRANCESCO, the celebrated doge of Venice, was elected to that office in 1423, and retained it for 34 years, dying in 1457, three days after his resignation. He did good service to his country, both by his foreign conquests and the excellence of his home administration. His domestic relations, however, were singular. He had the misfortune to lose three of his sons, and to see a charge of treason brought against the fourth and last, who was put on the rack and tortured before his own eyes, while he was himself compelled to acknowledge the justice of the whole trial. A very detailed and excellent account of the subsequent persecution of Foscari and his unfortunate son will be found in the second volume of Smedley's *Sketches of Venetian History*. Byron's tragedy of the *Two Foscari* is based upon this narrative.

FOSCOLO, Ugo, a distinguished Italian poet and miscellaneous writer, was born about 1777 on board a Venetian frigate, near Zante, in the Ionian Sea. While a mere boy he had the misfortune to lose his father, who was a physician and government-inspector of hospitals at Spalatro, in Dalmatia. He studied at the university of Padua, and after completing his studies there he removed to Venice without having adopted a profession. A good deal of mystery hangs over this period of his life, but he seems to have been preparing for a literary career, and produced in 1797, as the first fruits of his labours, his tragedy of *Thyestes and Ajax*. This play had very equivocal success on the stage, and so strongly was its author convinced of its worthlessness that he himself penned the severest criticism of it that appeared anywhere. In that same year the French, who with Bonaparte at their head had taken Venice with the professed object of republicanizing it, made it over once more to the Austrians. Foscolo, with some of the leading members of the patriotic party, retired to Milan, where he gave vent to his excited feelings in his *Lettere di Due Amanti* (afterwards republished under the title of *Le Ultime Lettere di Jacopo Ortiz*), a sort of political romance which had an immediate and prodigious success. The work possesses little interest as a novel, but is valuable for its pictures of Italian society in those troubled times, its beautiful style, its pathetic tone, and its occasional bursts of impassioned eloquence. In 1799 Foscolo volunteered into the Lombard legion, served in the disastrous campaign of that year, took part in the defence of Genoa under Masséna, and, after the battle of Marengo once more threw Lombardy into the hands of the French, retired into private life at Milan, and resumed his literary pursuits. In 1802 Bonaparte called together at Lyons a meeting of Italian deputies to sketch the plan of a constitution for the Cisalpine Republic, and Foscolo was invited to lay before the First Consul the real state of the country and the wishes of the people. He executed this commission with a boldness so startling that it was judged unsafe to submit the document to the First Consul; but it was afterwards printed at Milan, and serves to set in a very clear light the high and uncompromising spirit of its author. Italy had not heard her political condition and wants so boldly described since the days of Rienzi, perhaps of Tacitus. In 1807 Foscolo served, with the grade of captain of the staff, in an Italian regiment that belonged to the army destined for the invasion of England. In his leisure moments at St Omer he studied alternately military tactics and English literature, and executed part of a highly successful Italian version of Sterne's *Sentimental Journey*. After the breaking up of the camp at Boulogne, Foscolo abandoned the career of arms and retired to Brescia, where he composed his little poem *Dei Sepolcri*. This work, elicited by an order which forbade the erection of any memorial to departed worth or genius, was dedicated to Pindemonte, a kindred spirit, and immediately took rank as one of the highest flights of lyric power in the literature of modern Italy. In 1808 Foscolo was appointed professor of belles-lettres in the university of Pavia, and was privately warned by certain official friends to inaugurate his lectures with a tribute of praise to the Emperor Napoleon. Instead of doing this, though tempted with the promise of the cordon of the legion of honour, Foscolo delivered an opening address on the *Origin and Duty of Literature*, glowing with such a fiery eloquence, and informed by so daring a spirit of independence, that the orator incurred the suspicions of the government, and his chair was shortly afterwards suppressed. His tragedy of *Ajax*, though it had no great success when produced on the stage at Milan, did not tend much to conciliate for him the favour of the authorities, as it was believed that under the names of Agamemnon, Ajax, and Calchas, he had intended to paint Napoleon, Moreau, and Pius VII. A satire on the pedantry and sycophancy of certain influential academicians raised against him such a host of enemies that he was obliged to retire for a short time from Milan. At Florence, to which he now removed, he completed his translation of the *Sentimental Journey*, and produced his tragedy of *Ricciarda*, besides a variety of minor poetical pieces. In the political history of Northern Italy, after the abdication of Napoleon, Foscolo played a prominent part; but finding it useless to contend against the overwhelming numbers of the Austrians, he being moreover accused of tergiversation by his own party, he suddenly quitted Italy and fixed his residence at Hottingen near Zurich in Switzerland, where he earned a scanty livelihood for two years by his pen. In 1816, with a view to bettering his fortune, he came to England, where he formed literary connexions, and wrote many articles for the *Edinburgh* and *Quarterly Reviews*. In London he republished his *Ricciarda*, and wrote historical disquisitions on Dante, Petrarch, and Boccaccio, all displaying great knowledge and much critical sagacity. At the time of his death, which happened in 1827, he was engaged in superintending a valuable edition of Dante. His death, which was caused immediately by an attack of dropsy, was accelerated by pecuniary embarrassments which fretted his naturally irritable temper, and impelled him to literary exertion quite beyond his physical strength. Though the character of Foscolo was dashed by some strange eccentricities, he yet possessed qualities, both of head and heart, which gained firm friends for him in every country where he happened to fix his residence. The most striking of these peculiarities was his vanity, which prompted him in society to talk far more about his own exploits and sufferings than was consistent either with modesty or self-respect. This same weakness showed itself in his dramatic works, in which the hero is generally the *alter ego* of himself, and probably prevented him from realizing the prophecy which Alfieri made about him on witnessing his first play, and hearing that the author was only nineteen years of age:—"If that be true," said Alfieri, "then he will excel me." But this infirmity was far more than atoned for by the lofty independence of his character, which in the general prostration of Italy before Napoleon, enabled him to stand aloof, and offer the only opposition which that conqueror experienced from any native-born Italian. In the words of Pecchio, the biographer of Foscolo, "If, amidst the Asiatic idolatry towards Napoleon, any kind of opposition can be said to have existed in Italy, Foscolo must be considered the leader of it. Among a crowd of literati, who prostituted their character, he alone succeeded Alfieri in gathering around him those youths who felt the love of study and independence, and without uselessly challenging an irresistible power, he tempered with his principles and example their souls for present dignity and future resistance." Foscolo was no partizan, and refused to associate with such of his own countrymen as would have been content with anything less than the absolute and unconditional independence of Italy. His aspirations in literature and politics were high and noble, and his talents were never employed except in the cause of virtue. His dramatic productions are not very valuable; but his prose works are in point of style and matter among the most vigorous and original in the literature of modern Italy.

FOSSE, or Foss (from *fossus*, part. of *fodio* to dig), in *Fortification*, a ditch or moat; in *Anatomy*, a peculiar cavity in a bone, with a large aperture.

FOSS-WAY, a Roman military road in England, leading from Totness through Exeter to Barton on the Humber, and so called, says Camden, from the ditch on both sides.

FOSSANO, a city of Piedmont, province of Coni, Sardinia, situated on a lofty hill near the left bank of the Stura, 15 miles N.N.E. of Coni. The hill is crowned with an old castle, and the town itself is encircled by walls. It has an antique and rather gloomy appearance, the houses being

built upon ranges of arches under which are the footways. It has a cathedral, royal college, mineral baths, and manufactures of silk, paper, and leather. Pop. 16,000.

FOSSARII, in the ancient Eastern Church, officers appointed to bury the dead. Ciacconius relates that Constantine created 950 fossarii, and that they were exempted from taxes, services, burdensome offices, and the like.

FOSSIL, in a general sense, denotes anything that is dug out of the earth. But the word is generally used among geologists and mineralogists to designate either simple or compound mineral bodies, such as metals, stones, salts, earths, and other minerals, or, more commonly, the petrified forms of plants and animals which occur in the several strata of the earth. *Native* fossils are minerals, properly so called, as earths, salts, metallic bodies, &c. *Extraneous* fossils are bodies of the animal or vegetable kingdoms, accidentally buried in the earth; such as plants, shells, corals, bones, and other substances, most of which exist in a petrified state. See Geology.

FOSSOMBRONE, the ancient *Forum Sempronii*, a town of the Papal States, legation of Urbino e Pesaro, situated on the Metauro, here crossed by a handsome one-arched bridge, 7 miles E.S.E. of Urbino. The cathedral contains many good paintings and interesting inscriptions. In the vicinity, Asdrubal the brother of Hannibal was defeated and slain (207 B.C.) by the Romans. The inhabitants, amounting to about 5000, are chiefly engaged in agriculture, and in the manufacture of silk, which is said to be the finest in Italy.

FOSTER, John, generally distinguished as "*The Essayist*," was born in the parish of Halifax, Yorkshire, Sept. 17, 1770. His parents occupied a small farm-house between Wainsgate and Hebden-bridge, and maintained themselves partly by farming and partly by weaving. They were persons of earnest piety, and of strong intelligence, though of limited cultivation, with little book-knowledge except such as they obtained from some ponderous volumes of Puritan theology. They married rather late in life: John was their first-born, and they had no other child besides his brother Thomas, who was four years younger—circumstances not favourable to the development of the social qualities. From childhood his character was marked by a sharply-defined individuality. To use his own expressive language, he felt "as if dissociated from the whole creation," and recoiled from human beings into a cold interior retirement. His outward life was marked by timidity and "infinite shyness;" his interior life was crowded and agitated with incommunicable feelings. His antipathies were strong, though not malicious, and his associations intensely vivid. For a number of years he would not sit on a stool which belonged to a man who died in a sudden and strange way, and whose ghost was said to have appeared in a barn near his house. His emotions were strongly roused by passages in favourite authors, such as Young's *Night Thoughts*. Single words (as *chalcedony* or *hermit*) or the names of ancient heroes had a mighty fascination for him. But while he felt isolated and shut out from human sympathy, he found relief and exquisite delight in the contemplation of natural scenery. "Sweet nature!" he exclaimed many years after, "I have communed with her with inexpressible luxury." A flower, a tree, a bird, a fly, was enough to kindle a delightful train of ideas and emotions, and sometimes to elevate the mind to sublime conceptions. Yet, in very early life, the *great* interested him more than the *beautiful*. Great rocks, vast trees and forests, emphatically dreary, caverns, volcanos, cataracts, and tempests, were, in reading and fancy, the objects of his highest enthusiasm; and in the contemplation of human character he preferred the bold and the heroic. Filled with restless thoughts and aspirations, he felt as a foreigner in his native place, and some of his earliest musings were on plans for leaving it. The dull monotonous occupation of weaving, in which he assisted his parents, and the utter want of sympathy in those around him, increased his disgust with his position. He performed the tasks assigned him with evident signs of repugnance, and in a manner which showed little aptitude for them; yet his general conduct was exemplary, reverential to his parents, and very free from any marked irregularity.

As a compensation for much that was undesirable in his social relations, the moral and religious influences he was under were powerful and salutary. His impressions of religion assumed as early as his fourteenth year a decided form. Just after the completion of his seventeenth year he joined the religious society of which his parents were members—that of the Baptist denomination—at Wainsgate Their pastor was Dr John Fawcett, a man venerable for his piety, with talents devoid of brilliancy but assiduously cultivated, and who combined with a puritanic theology an extensive acquaintance with English literature (including works of fiction), which placed him, in point of mental cultivation, far ahead of his co-religionists in Yorkshire and the neighbouring districts. For many years Dr Fawcett conducted a flourishing seminary at Brearley Hall, which was subsequently carried on by his son at Ewood Hall. With him young Foster was placed for the purposes of general education and of preparation for the ministerial office, in accordance with his own inclination and the wishes of his friends, who had some perception of his mental superiority. Part of each day was still spent in his customary employments at home; but, to make up for this interruption of his studies whole nights were frequently devoted to reading and meditation, *sub dio*, in his preceptor's garden. His school exercises were accomplished slowly and laboriously, which was the case with all his literary performances. At Brearley he had access to a large and miscellaneous library; he was most interested with voyages and travels, and these constituted throughout life his favourite reading. On leaving Brearley he proceeded to the Baptist college at Bristol, at that time (1791) and for some years later the only theological institution belonging to that denomination. The Rev. Joseph Hughes, the originator and dissenting secretary of the Bible Society, was then the classical tutor, having succeeded Robert Hall, who had just removed to Cambridge. Foster remained only a twelvemonth at Bristol, and, if his own statement be taken as correct, without much improvement in scholarship; but during that period he gained the friendship of Hughes, visited Hannah More and her sisters at Cowslip Green, and listened for the first time to the eloquence of Hall. On leaving Bristol he spent three months at Newcastle-on-Tyne, where he preached to a very small audience, and whiled away his leisure time in desultory musings, conscious of possessing superior powers, but neither happily combined nor fully brought out. After visiting his Yorkshire friends he went to Ireland, where he spent little more than a year, in Dublin, first as a preacher, and then as a schoolmaster, but failed to establish himself in either capacity. Early in 1797 he became the minister of a general Baptist church at Chichester; here he remained for two years and a half, and though his religious earnestness increased, it produced little effect on his hearers. We next find him at Battersea, visiting his friend Hughes, and instructing twenty-one young Africans brought over by Zachary Macaulay from Sierra Leone. In 1800 he removed to Downend, a village five miles from Bristol, and preached alternately in a small chapel there, and in another at Fishponds belonging to a lunatic asylum then under the management of Dr Joseph Mason Cox, whose brother-in-law he afterwards became. In 1804, on the recommendation of Robert Hall, who described him as "a young man of the most original and extraordinary genius, of unexceptionable character, and of the most amiable temper," he became minister of a congregation at Frome. The characteristics

Foster.

of his preaching at this period have been traced with great fidelity by his friend (and constant hearer) Mr Sheppard. "The sermons of Foster," he remarks, "were of a cast quite distinct from what is commonly called oratory, and indeed from what many seem to account the highest style of eloquence, namely, a flow of facile thoughts through the smooth channels of uniformly elevated polished diction, graced by the utmost appliances of voice and gesture. They were distinguished by an unambitious and homely sort of loftiness, which displayed neither phrase nor speaker, but things, while the brief word and simple tone brought out the sublime conception 'in its clearness' by a fund of varied associations and images, by graphic master-strokes, the frequent hints of profound suggestion for after meditation, by cogent though calm expostulations and appeals, and by shrewd trains of half-latent irony against irreligion and folly, in which, without any descent from seriousness and even solemnity, the speaker moved a smile by his unconscious approach to the edge of wit, yet effectually quelled it by the unbroken gravity of his tone and purpose."

After two years a swelling in the thyroid gland, which constant public speaking, and even much talking in company, tended to aggravate, obliged Mr Foster to resign his charge at Frome. He had also a growing conviction that the press, and not the pulpit, was the chief medium through which he could efficiently employ the talents committed to his trust. For some time, evidently with a view to authorship, he had committed to paper observations on natural objects, illustrations of human character, and reflections on morals and religion, in an aphoristic form. Many of these contain the germ, and even the exact phraseology, of passages to be found in his published writings. During his residence at Frome he wrote and published the *Essays*, which at once established his reputation "as (to use Sir James Mackintosh's language) one of the most profound and eloquent writers that England has produced." Within little more than a twelvemonth they passed through three editions; the eighteenth appeared in 1845, and since that time their circulation has been unabated. Multitudes of young persons have regarded as a bright era in their mental history the hour when this volume first came into their hands, and have never ceased to rejoice in its stimulating and elevating influence on their faculties. It has been to them a dayspring revealing a world of living beauty and wonders where all was before involved in deathlike torpor and gloom. Its intellectual power and deep-toned eloquence has dissolved in many minds the unhappy and absurd association of piety with mental weakness and vulgarity; while, on the other hand, it has released from their trammels not a few who had been wont to regard general literature and freedom of thought as the exclusive property of the profane. The last of the four essays, *On some of the Causes by which Evangelical Religion has been rendered unacceptable to Persons of Cultivated taste*, has probably contributed more than anything else to that reformation in style which is perceptible in our modern religious literature, and of which Foster himself in his posthumous lectures has given so many beautiful specimens.

Before leaving Frome, Foster commenced writing in the *Eclectic Review*, and for the next twelve years contributed from ten to above twenty articles annually. In May 1808 he married the lady to whom his Essays were originally addressed in an epistolary form, and with whom his acquaintance had commenced seven years before at Battersea. Her mother and two of her sisters resided at Bourton-on-the-water, a retired, respectable village in Gloucestershire. To this place he removed on his marriage, which proved an eminently happy one. Here he led a very secluded life, writing reviews during the week, and on Sundays preaching in the neighbouring villages: the latter employment he valued as aiding his own piety, and keeping up an acquaintance with mankind. While at Bourton he lost both his parents, and became the father of five children, two of whom died in infancy. In 1817 he returned to Downend, where he wrote his *Essay on the Evils of Popular Ignorance*, in which he warmly urges the necessity of a national system of education, and portrays with appalling truthfulness the barbarism existing in our masses; a repulsive spectacle, which he terms "a gloomy monotony: death without his dance." Having relinquished his ministerial office at Downend, and removed to the neighbouring village of Stapleton, about two miles from Bristol, he delivered a series of discourses at Broadmead chapel, which were well attended by persons of almost all denominations. On Robert Hall's settlement in Bristol, he declined to continue this service, saying, "Now *Jupiter* is come, I can try it no more." Most of these discourses were published soon after his decease, and have lately been reprinted by Mr Bohn in his Standard Library. In 1826 his only son, an amiable, thoughtful youth, died of consumption. Six years later he was deprived of his inestimable wife, to whom he felt himself indebted not only for a very great portion of happiness, but for whatever mental improvement he had made during their married life, a period of five and twenty years. Her intellect was remarkably strong and correct, and in refinement of perception and depth of reflective feeling she had few equals. This event deepened his constitutional pensiveness, and prompted him to indulge more than ever in those intense musings on the state after death, "the secrets of the invisible world," which form an ever-recurring topic in his correspondence. In addition to this greatest loss, he found himself, by the deaths of Hall, Hughes, and others, standing almost alone, bereft of the companions of his youth and mature life. His latter days were, however, soothed by the affectionate attentions of his two daughters who resided with him. After languishing for some weeks in a state of devout preparation for the final event to which he looked forward with a calm dignity and a childlike humility that were most impressive, he expired quietly and (as he wished) alone, October 15, 1843.

Besides the works already mentioned, Foster published a *Discourse on Missions* in 1818; an *Introductory Essay to Doddridge's Rise and Progress of Religion* (since reprinted separately) in 1825; and *Observations on Mr Hall's Character as a Preacher*, appended to Dr Gregory's Memoir in the collected edition of Hall's Works, 1832. He also wrote *An Introduction* to a pamphlet by Dr Marshman in vindication of the Serampore Missionaries. He was the author (anonymously) of *Two Letters on the Established Church*, addressed to the editor of the *Morning Chronicle*; and of *Five Letters* (in the same journal) *on the Ballot*, of which he was a strenuous advocate; these and *Nine Letters of Religious Advice and Consolation* to an interesting young person (the niece of his friend Mr Cottle) in her last illness, will be found in his *Life and Correspondence*, 2 vols., the third edition of which has lately appeared in Bohn's Standard Library.

His contributions to the *Eclectic Review* amounted to 185 articles, of which Dr Price published a selection, containing 59 papers, in 1844. (J. E. R.)

Fothergill.

FOTHERGILL, Dr John, an eminent physician, was born of Quaker parents, in 1712, at Carr End in Yorkshire. The doctor was the second of five children, and received his education under the care of his grandfather Thomas Hough, a person of fortune in Cheshire, and at Sedburgh in Yorkshire. Having served his time to an apothecary at Bradford, he removed to London, and became a pupil of Dr Wilmot, at St Thomas's Hospital. He then went to the university of Edinburgh for the purpose of studying medicine, and there took his degree. From Edinburgh he went to Leyden: but after a short stay he returned to London, and began to practise about the year 1740, in a

house in White-hart Court, Lombard Street, where he resided during the greater part of his life, and acquired most of his fortune. In 1746 he was admitted as a licentiate of the College of Physicians in London; and in 1754 as a fellow of that of Edinburgh, to which he was a considerable benefactor. He afterwards became a member of the Royal Medical Society at Paris, as well as of the Royal and Antiquarian Societies. He continued his practice with uninterrupted success till within the last two years of his life, when an illness, which had been brought on by unremitting labours, obliged him to give up a considerable part of it. Besides his application to medical science, he had imbibed an early taste for natural history, and devoted his leisure to conchology and smaller objects of botany. His pamphlet on the ulcerous sore throat is the best of his publications, but it owes much of its merit to the prior information of Dr Letherland. It was printed in the year 1748, on the re-appearance of that fatal disorder which in 1739 had carried off the two sons of Mr Pelham. He was the patron of Sidney Parkinson, and drew up the preface to his account of the voyage to the South Seas. At his expense also was made and printed an entirely new translation of the Bible, from the Hebrew and Greek originals, by Anthony Purver, a Quaker, in two volumes, 1764, folio; and also, in 1780, an edition of Bishop Percy's *Key to the New Testament*, adapted to the use of a seminary of young Quakers at Ackworth. In the influenza of 1775 and 1776, he is said to have had sixty patients on his list daily, and his profits were estimated at L.8000 per annum. The disorder which hastened his death was a schirrus of the prostate gland, and an obstruction of the bladder. He died at his house in Harpur Street, in the month of December 1780, and his remains were interred in the Quakers' burying-ground at Winchmore Hill. The doctor by his will appointed that his shells and other specimens of natural history should be offered to Dr Hunter at L.500 under the valuation which he had ordered to be taken of them, and accordingly Dr Hunter bought them for L.1200. His drawings and collections in natural history were also offered to Sir Joseph Bankes at a valuation. His English portraits and prints, which had been purchased by him for eighty guineas, were bought by Mr Thane for two hundred guineas. His books were sold by public auction.

FOTHERINGAY CASTLE, in which Mary Queen of Scots was long confined, and was beheaded 8th Feb. 1587, is situated in Northamptonshire, 3½ miles N.N.E. of Oundle. It was demolished by order of her son, James I. of England.

FOUCHÉ, Joseph, Duke of Otranto, minister of police under Napoleon, was born at Nantes in 1763. In the oratoire of that city where he was educated he distinguished himself by his proficiency in the various departments of study, and on leaving it taught successively in the colleges of Juilly, Arras, and Vendôme. The outbreak of the Revolution found him settled quietly in his native town, practising as an advocate. In 1792 he was returned to the National Convention as member for the department of Loire Inférieure, and in this capacity voted for the death of the king, without the right of appeal to the people. Having earned the character of a zealous republican by his conduct at Nièvre, where he suppressed public worship, plundered the churches, imprisoned the priests, and decreed materialism by inscribing over the entrance to the town cemetery, "La mort est un Sommeil éternel." Fouché was associated with Collot d'Herbois in that frightful mission which razed Lyons to the ground, and deluged the south of France with blood. On his return to Paris he was made president of the Jacobin Club, though he was shortly afterwards expelled from it altogether by the intrigues of Robespierre. Fouché avenged this disgrace by doing his best to bring about the downfall and death of Robespierre; but he was himself seized and imprisoned as a dangerous terrorist; and though he was released under the act of general amnesty in 1795, yet, finding his enemies become more numerous and powerful, he judged it prudent to retire for a while into the obscurity of private life. In 1798 he was engaged in the public service in Italy; and on returning home was appointed to the ministry of police, a situation for which he was eminently qualified by his unscrupulous boldness, his matchless cunning, and his capacity for intrigue. Having assisted Bonaparte in his rise, he was continued in office, and contrived to stand well both with that conqueror and with the royalists, whom he frequently screened from Napoleon's vengeance. In the foreign wars of the emperor, Fouché's system of espionage preserved the internal tranquillity of France. Sometimes, as in the case of the English expedition against Holland in 1809, he acted with an independent boldness that accorded very ill with the dictatorial mind of his master. On that occasion he called forth the national guard; and in his address to them said, "Let us show Napoleon that his presence is not indispensable for the repulsion of the enemies of France." Napoleon both hated and feared him, but wisely consulted his own interests in employing and promoting him. In 1809 Fouché was made Duke of Otranto, but was obliged in that year to retire into the country for a time. In 1810 he was made governor of Rome, and in 1813 of the Illyrian provinces, and afterwards of Naples. During the Hundred Days he resumed his old functions of minister of police, and after Waterloo strongly urged Napoleon to abdicate, while he secured his own interest with the Bourbons at Ghent. His services were retained for a while by Louis XVIII.; but in 1816 he shared the fate of the surviving revolutionists who had voted for the death of Louis XVI., was banished from France, and deprived of his estates. He died at Trieste in 1820, leaving behind him an enormous fortune. His memoirs, which were published in France in 1824, were not acknowledged by his sons; but there are good reasons for believing them to be authentic. Various attempts have been made to defend the character of Fouché, but with very indifferent success. The best thing that can be alleged in his favour is, that he does not appear to have been a coward. It is to be doubted if the French Revolution produced a worse man than Fouché. He was only less bloodthirsty than Collot d'Herbois, and less of a hypocrite than Barrère. In cunning and the unscrupulous abuse of great power, a parallel, or even a second to him is not to be found in these disjointed times. In such a man it would be too much to look for honesty of purpose or single-heartedness of aim, and accordingly we find him, though fulfilling his official duties as they never were fulfilled before or since, animated throughout his whole career solely by the principle of an ambitious self-interest. He succeeded so well, that it may be doubted if even Napoleon himself exercised a more despotic power in France during the period of his reign than did his formidable minister of police. Much light is thrown on Fouché's character, and the hidden workings of his political machinery, in the *Témoignages Historiques, ou quinze ans de haute police sous Napoléon*, par Desmarets.

FOUGASSE, in the art of war, a small mine in which the chambers are placed from 3 to 10 feet under ground, dug under some work, fortification, or post, and charged with sacks of powder, or powder placed in a chest, and covered with earth and stones. They are very efficient in defending works, especially if placed near the foot of the glacis or ditch. The powder is fired, as in larger mines, by means of a saucisson. Fougasses are also formed by burying several loaded shells with the fuse downwards.

FOUGÈRES, the capital of a cognominal arrondissement in the department of Ille-et-Vilaine, France, stands on an eminence near the left bank of the Nançon, 24 miles N.E. of Rennes. This was formerly one of the strongest

places in Brittany, and frequently figures in history from the eleventh to the fifteenth centuries. It was taken by the English in 1202, and again in 1448. During the last century it suffered from four destructive fires, so that few of its ancient buildings now remain. It is a pleasant town, and has some mineral springs, which attract numerous visitors. Its trade and manufactures are considerable, the former in agricultural and dairy produce, the latter of sail-cloth and hempen fabrics, flannels, hats, leather, &c. Pop. (1851) 8771.

FOULA, or Fowla Island, one of the Shetland Isles, lying between six and seven leagues west from Mainland. It is about three miles in length, narrow, and full of rugged, steep, and bare rocks. Its summit has an elevation of 1350 feet. Foula, it has been conjectured, is the Thule of Tacitus. It is pastoral, and maintains a few families.

FOULAHS, a people of Africa. See Africa, vol. ii., p. 222.

FOULIS, Robert and Andrew, supposed to have been natives of Glasgow, were two learned printers, and passed their lives in comparative obscurity. They succeeded, however, in establishing a press, and from it issued some of the most accurate and elegant editions of standard works that were produced during the eighteenth century. Robert's first attempt was about 1740, which ended in the publication of an excellent 4to edition of *Demetrius Phalereus* in 1743. Next appeared his immaculate 12mo edition of Horace, of which the sheets, as they were struck off, were suspended in the college at Glasgow, and a reward offered to those who should point out an inaccuracy. Soon after the publication of this famous edition of Horace, the brothers entered into partnership, and continued during 30 years to issue a series of the classics and other works, printed in the most accurate and elegant manner. Of these the most remarkable are the small editions of Cicero, Tacitus, Cornelius Nepos, Virgil, Tibullus and Propertius, Lucretius, and Juvenal; a beautiful edition of the Greek Testament, in small 4to; Homer, fol. 4 vols., 1756-1758; Herodotus, Greek and Latin, 9 vols. 12mo, 1761; Xenophon, Greek and Latin, 12 vols. in 12mo, 1762-1767. To these we may add Gray's Poems; Pope's Works; Hales of Eton, &c.

It is sad to relate that these learned, indefatigable, and successful men were at length ruined by their taste for the fine arts. This was brought about by their establishment of an academy for the instruction of youth in sculpture and painting, but chiefly by the enormous expense incurred in sending young artists to Italy to copy the ancients. They found the city of Glasgow a very ungenial soil into which to transplant the imitative arts; and thus after having realized ample fortunes by their classical publications, they died in poverty, after having parted with the last of their paintings at Christie's in Pall Mall. Andrew died in 1775, and Robert in 1776.

FOULQUES, the name of a distinguished French family, which produced a number of famous warriors and counts of Anjou. The principal of them were—Foulques I., called *le Roux*, Count of Anjou, who succeeded his father, Ingelger, in 888 A.D. He made war upon the Bretons and Normands, and died in 938. Foulques II., called *le Bon*, son of the preceding, and succeeded by Geoffroi I.; Foulques III., called *Nerro* or *le Noir*, son of the last-mentioned; Foulques IV., called *le Rechin*; and Foulques V., called *le Jeune*, son and successor of the preceding, in the year 1109.

FOUMART, the pole-cat. See index to Mammalia.

FOUNDERY, or Foundry, the art of melting and casting metals. See Copper-Smelting; Iron-making; Furnace.

Foundery of Small Works, or Casting in Sand. The sand commonly used for casting small works is at first of a pretty soft, yellowish, and clammy nature; but it being necessary to strew charcoal dust in the mould, it at length becomes of a quite black colour. The sand is worked over and over, on a board, with a roller and a kind of knife; and is placed over a trough to receive it, after it has by these means been sufficiently prepared.

This being done, the workmen take a wooden board of a length and breadth proportional to the things to be cast, and putting a ledge round it, they fill it with sand a little moistened, to make it duly cohere. They then take either wood or metal models of what they intend to cast, and apply them to the mould, and press them into the sand so as to leave their impression there. Along the middle of the mould is laid half a small brass cylinder, as the chief canal for the metal to run through, when melted, into the models or patterns; and from this chief canal are placed several others, which extend collaterally to each model or pattern placed in the frame. After this frame is finished, they take out the patterns, by first loosening them all round, that the sand may not give way; then they proceed to work the other half of the mould with the same patterns in just such another frame, only that it has pins, which, entering into holes corresponding to it in the other, make the two cavities of the pattern fall exactly on each other.

The frame, thus moulded, is carried to the melter, who, after extending the chief canal of the counterpart, and adding the cross canals to the several models in both, and strewing mill dust over them, dries them in a kind of oven prepared for the purpose. Both parts of the mould being dry, they are joined together by means of the pins; and to prevent them giving way, by reason of the melted metal passing through the chief cylindrical canal, they are screwed or wedged up as in a press.

Whilst the moulds are thus preparing, the metal is fusing in a crucible of a size proportional to the quantity of metal intended to be cast. When the moulds have cooled, the frames are unscrewed or unwedged, and the cast work is taken out of the sand, which sand is worked over again for other casting.

Foundery of Statues. The casting of statues depends on the due preparation of the pit, the core, the wax, the outer mould, the inferior furnace to melt off the wax, and the upper to fuse the metal.

The pit is a hole dug in a dry place, somewhat deeper than the intended figure, and made according to the prominence of certain parts of it. The inside of the pit is commonly lined with stone or brick; but when the figure is very large, they sometimes work on the ground, and raise a proper fence to resist the impulsion of the melted metal. The inner mould, or core, is a rude mass, to which is given the intended attitude and contours. It is raised on an iron grating strong enough to sustain it, and is strengthened within by several bars of iron. It is generally made either of potters' clay mixed with cow-hair, or of plaster of Paris mixed with brick-dust. The use of the core is to support the wax and the shell, and lessen the weight of the metal. The iron bars and the core are taken out of the brass figure through an aperture left in it for that purpose, which is soldered up afterwards. It is necessary to leave some of the iron bars of the core, which contribute to the steadiness of the projecting part, within the brass figure. The wax is a representation of the intended statue. If it be a piece of sculpture, the wax should be all from the hand of the sculptor himself, who usually forms it on the core; though it may be wrought separately in cavities, moulded on a model, and afterwards arranged on the ribs of iron over the grating, filling the vacant space in the middle with liquid plaster and brick dust, by which means the inner core is proportioned as the sculptor carries on the wax. When the wax, which is of the intended thickness of the metal, is finished, small waxen tubes perpendicular to it from top to bottom are filled, to serve both as canals for the conveyance

of the metal to all parts of the work, and as vent-holes to give passage to the air, which would otherwise occasion great disorder when the hot metal came to encompass it.

The work being brought thus far, must be covered with its shell, which is a kind of crust laid over the wax, and which being of a soft matter, easily receives the impression of every part, which is afterwards communicated to the metal upon its taking the place of the wax, between the shell and the mould. The matter of this outer mould is varied according as different layers are applied. The first is generally a composition of clay and old white crucibles well ground and sifted, and mixed up with water to the consistence of a colour fit for painting; and it is applied with a brush, by means of which it is laid on seven or eight times successively. For the second impression horse-dung and natural earth are added to the former composition; but for the third impression only horse-dung and earth are used. Lastly, the shell is finished by laying on several more impressions of this last matter, made very thick with the hand. The shell, thus finished, is secured by several iron girths bound round it, at about half a foot distant from each other, and fastened at the bottom to the grating under the statue, and at top to a circle of iron where they all terminate.

If the statue be so large that it would not be easy to move the moulds with safety, these must be wrought on the spot where it is to be cast. This is performed in two ways. In the first place, a square hole is dug in the ground, much larger than the mould to be made therein, and its inside is lined with walls of freestone or brick. At the bottom is made a hole of the same materials, with a kind of furnace, having its aperture outwards; and in this a fire is made, to dry the mould, and afterwards melt the wax. Over this furnace is placed the grating, and upon this the mould, formed as above. Lastly, at one of the edges of the square pit is made another large furnace, to melt the metal. In the other way, it is sufficient to work the mould above ground, but with the precaution of a furnace and grating underneath. When finished, four walls are run around it, and by its side a melting furnace is prepared. For the rest, the method is the same in both cases. The mould being finished, and inclosed as described, whether below ground or above it, a moderate fire is lighted in the furnace under it, and the whole covered with planks, that the wax may melt gently down, and run out at pipes contrived for that purpose at the foot of the mould, which are afterwards exactly closed with earth, as soon as the wax is all carried off. When this is done, the whole is filled up with bricks thrown in at random, and the fire in the furnace augmented, until both the bricks and mould become red hot. The fire is then extinguished, and everything being cold again, the bricks are taken out, and their place filled up with earth, moistened, and beaten a little at the top of the mould, in order to render it the firmer. These preparatory measures being duly taken, there remains nothing but to melt the metal, and run it into the mould. This is done by means of the furnace above described, which is commonly made in the form of an oven with three apertures, one to put in the wood, another for a vent, and a third to run the metal out at. From this last aperture, which is kept very close whilst the metal is in fusion, a small tube is laid, by which the molten metal is conveyed into a large earthen basin, over the mould, into the bottom of which all the large branches of the jets or casts, which are to convey the metal into the different parts of the mould, are inserted.

These casts or jets are all terminated with a kind of plugs, which are kept close, so that, upon opening the furnace, the brass, which rushes out with violence, may not enter any of them till the basin be full enough of matter to run into them all at once; upon which occasion they pull out the plugs, which are long iron rods with a head at one end, capable of filling the whole diameter of each tube. The whole of the furnace is then opened with a long piece of iron fitted at the end of each pole, and the mould filled in an instant. This completes the work in relation to the casting part; the rest is the sculptor's or carver's business, who taking the figure out of the mould and earth with which it is encompassed, saws off the jets with which it appears covered over, and finishes it with chisels, gravers, puncheons, and other instruments. See also CASTING.

FOUNDERY of Bells. The metal for casting bells, it is to be observed, is different from that employed for casting statues; there being no tin in the statue metal, whereas in the bell metal there is a fifth, and sometimes more.

The dimensions of the core and the wax for bells, especially a chime, are not left to chance, but must be measured upon a scale, or diapason, which gives the height, the aperture, and the thickness, necessary for the several tones required. It is on the wax that the several mouldings and other ornaments and inscriptions, to be represented in relief on the outside of the bell, are formed. The clapper or tongue is not properly part of the bell, but is furnished from other hands. In Europe it is usually of iron, with a large knob at the extremity; and is suspended in the middle of the bell. In China a wooden mallet is used, which is struck by the hand against the bell; and hence the Chinese bells can have comparatively little resonance. The Chinese have a method of increasing the sound of their bells, by leaving a hole under the cannon; but this our bell-founders would reckon a defect.

The proportions of our bells differ very much from those of the Chinese. In ours, the modern proportions are, to make the diameter fifteen times the thickness of the brim, and the height twelve times. The parts of a bell are, first, the sounding bow, terminated by an inferior circle, which grows thinner and thinner; secondly, the brim, or that part of a bell whereon the clapper strikes, and which is thicker than the rest; thirdly, the outward sinking of the middle of the bell, or the point under which it grows wider to the brim; fourthly, the waist or furniture, and the part that grows wider and thicker quite to the brim; fifthly the upper vase, or that part which is above the waist; sixthly, the pallet, which supports the staple of the clapper within; and, seventhly, the bent and hollowed branches of metal uniting with the cannons, to receive the iron keys, by which the bell is hung up to the beam, and which forms its support and counterpoise when rung out.

Without entering into the details of the operations, we may state, that the business of bell-foundery is reducible to three heads; first, the proportion of a bell; secondly, the forming of the mould; and, thirdly, the melting of the metal.

FOUNDERY of Cannon, &c. See CANNON-MAKING.

Letter-FOUNDERY, or *Casting of Printing Letters.* See TYPE-MAKING, and PRINTING.

FOUNDLING HOSPITALS are charitable institutions established in most large towns in Europe, for the reception of children exposed or deserted by their parents. The exposing of children was a common practice among the nations of antiquity; for notwithstanding that infanticide might be practised with impunity, yet natural feeling would prompt parents to expose their children rather than become the immediate instrument of their death. For this purpose they generally selected such places as were much frequented, where there was a chance of their attracting the notice of the benevolent. In Athens and Rome there were places set apart for the purpose. The children so found were declared to be the slaves or absolute property of those by whom they were reared. Some of these were saved from death, not from humane motives, but that their foster-fathers might, by mutilating their persons, and exhibiting them in the streets, obtain an infamous livelihood from the alms given them by passers-by. This detestable practice seems to have been carried on pretty extensively and it is even

vindicated by Seneca, upon the ground of their being slaves. "*Gallio fecit illam questionem:—An in expositis lædi possit respublica? Non potest, inquit. An lædi possit in aliquâ suâ parte? Hæc nulla reipublicæ pars est; non in censu illos invenies, non in testamentis.*" (*Senecæ Controvers.*, v. 33.) In the fourth century the exposure of children was prohibited by Valentinian, Valens, and Gratian; but the edicts of these emperors were only partially effective, the slavery of these unfortunates continuing till the year 530, when it was abolished by Justinian. Even in ancient times the state made provision for the preservation of foundlings; but the institution of *foundling hospitals* is of later date. The first distinct trace of an express foundation of this kind is at Milan, in 787. In the year 1198, Innocent III. allotted a part of the great hospital of Spirito Santo at Rome to the reception of foundlings; and with a view to prevent the crime of infanticide, by affording persons every facility for depositing their illegitimate children without the risk of being recognized, there was fixed in the wall of the hospital a turning-box, in which the infant was placed, and taken in upon a signal being given by ringing a bell. The same secret mode of admission was afterwards adopted in many similar institutions on the Continent, and at a later period in those of London and Dublin. This facility of disposing of children led, as might have been foreseen, to very great abuses; since any woman, of whatever rank, might thus avoid the stigma of appearing as the mother of an illegitimate child; and unnatural parents, rich or poor, could avoid the expense and trouble of rearing their own children. This system has been said to find favour in some countries on account of the numbers it furnishes for the military service. The great foundling hospital of Paris was established in 1620, and up to the year 1807 had received 464,628 children. The number of foundlings in France in 1784 amounted to 40,000; in 1798 to more than 51,000; and in 1822 to 138,500. In 1847, out of 918,581 children born in France, the illegitimate births amounted to 65,626, and the foundlings to 27,284. The proportion of illegitimate children in Paris is one in every three births; and of the total number of illegitimate children, about 58 out of every 100 become inmates of the foundling hospital, where nearly two-thirds of them die before they are a year old. (See Guerry, *Statistique Morale de la France;* and Benoiston de Châteauneuf, *Considérations sur les Enfans-trouvés dans les Principaux états de l'Europe.*) According to the *Annuaire du Bureau des Longitudes* for 1855, the total number of births in Paris in 1853 was 34,049, of which 10,833 were illegitimate.

The mortality in foundling hospitals has always been very large, though this evil has been greatly mitigated by improved management, and the practice of giving out the children to be nursed. Our own country, when such institutions existed in their original form, was no exception to this reproach; for about the middle of last century, out of 14,934 children received into the London Foundling Hospital during a period of rather less than four years, only 4400 lived to be apprenticed to trades; and in that of Dublin the mortality during the six years ending 1797, was probably unparalleled by any other institution of the kind. The Foundling Hospital of London was founded in 1739; but it was soon discovered that the funds of the institution were quite inadequate for its support, so great was the influx of inmates; and in consequence of the enormous abuses to which the facility of admission rendered the system liable, it became necessary to modify the character of the institution, or rather to convert it into a kind of orphan asylum. In 1760 a total change was effected in its constitution by authority of the legislature, and it then ceased to be a receptacle for foundlings. No child whose mother does not personally appear, and who cannot satisfactorily answer the questions put to her, is received: if, however, the mother can show that she had previously borne a good character, and that, owing to the desertion of the father, she is unable to maintain the child, it is admitted, but not otherwise.

The arguments for and against foundling hospitals are very nicely balanced, and the problem is one that is extremely difficult to solve. On the one hand it is undeniable that they render the crime of infanticide and abortion less frequent, and that in the majority of cases the children are better nursed and educated than they could be at home by bad parents and bad nurses; while, on the other hand, it is objected that such institutions powerfully contribute to the corruption of morals. It seems to be the prevailing opinion in this country, that the influence of these establishments has been on the whole more pernicious than beneficial; that they have rarely accomplished their object; but that instead of preventing crime, they scatter its seeds and spread its roots on all sides. (See M'Culloch's *Principles of Political Economy.*)

FOUNT, or Font, among printers, a set of characters or letters of each kind, cast by a letter-founder, and sorted. A complete font includes the running letters, large and small capitals, single letters, double letters, points, commas, lines, and numeral characters in their established proportions, according to the language. See Type-Founding, and Printing.

FOUNTAIN, a spring or source of water rising out of the earth. Among the ancients, fountains generally were esteemed sacred; but some more especially so than others. The good effects resulting from cold bathing appears to have given rise to the belief that springs and rivers derived their salutary influence from some presiding deity. It was customary to throw little pieces of money into springs, lakes, or rivers, in order to render the presiding divinities propitious; as the touch of a naked body was supposed to pollute their hallowed waters. For the phenomena, theory, and origin of fountains or springs, see Physical Geography; Springs; Artesian Wells; and General Index.

Artificial fountains, of which there are various kinds, are all formed by pressure of some kind or other upon the water, viz., by the pressure or weight of a head of water, or by the pressure arising from the spring and elasticity of condensed air.

Fountain-Tree, or *Til-Tree*, a very extraordinary tree said to have existed formerly in the island of Hierro, one of the Canaries, and to have distilled water from its leaves in such abundance as to satisfy the requirements of those who lived near it. Whether such a tree ever existed is questionable; yet various writers have mentioned the fountain-tree of Hierro in apparently good faith. Glasse, in his *History of the Canary Islands*, published at London in 1764, alludes to it in the following terms:—"Many writers have made mention of this famous tree, some in such a manner as to make it appear miraculous; others again deny the existence of any such tree, among whom is Father Feyjoo, a modern Spanish author, in his *Teatro Critico.* But he, and those who agree with him in this matter, are as much mistaken as those who would make it appear to be miraculous. This is the only island of all the Canaries which I have not been in; but I have sailed with natives of Hierro, who, when questioned about the existence of this tree, answered in the affirmative."

FOUR BOROUGHS' COURT, an ancient Scottish court, so called because composed of delegates from four royal burghs; originally the burghs of Edinburgh, Stirling, Berwick, and Roxburgh; but from the year 1348, when the last two burghs were in the hands of the English, the burghs of Edinburgh, Stirling, Lanark, and Linlithgow. These delegates were assembled yearly at Haddington, before the Lord Chamberlain of Scotland, and formed for appeals from the burgh courts and chamberlain ayres, a court which was to the inhabitants of the burghs what the high

court of parliament was to the other inhabitants of the kingdom, the highest and ultimate court of appeal.

In 1405, when the regent, Robert Duke of Albany, uncle to King James I., was lord chamberlain, a court of the four burghs was held at Stirling, where it was resolved that deputies from the royal burghs south of the Spey should convene yearly with the four burghs, to consider and conclude on all matters affecting the common weal of all the royal burghs. This convention, though at first assembled with the court of four burghs, does not appear to have ever formed a constituent part of the latter assembly, and it seems also soon to have disregarded both the place and time of its meeting; for in 1487 its constitution was materially improved, representatives from all the royal burghs, "baith south and north," being by a statute of that year appointed to meet in convention yearly at Inverkeithing, "there to commoun and treate upon the weilfare of merchandice, the gude rule and statutes for the common profite of burrowes, and to provide for remeid upon the skaith and injuries sustained within the burrowes."

The chamberlain ayres, which had long been regarded by the nation as a grievance demanding immediate reformation, were thus substantially superseded, and accordingly soon afterwards fell into disuse. The court of four boroughs continued somewhat longer; but on the institution of the Court of Session, which was vested with a universal civil jurisdiction, its judicial functions were swallowed up, and it likewise expired. The office of lord chamberlain itself also, falling into the hands of the nobility and court favourites, ceased to be exercised; and his place in the convention came to be occupied by the Lord Provost of Edinburgh, who, though not a member, is the constant preses of the convention. The origin of this last circumstance, hitherto, we believe, unexplained by our writers, seems to be this. The convention was, by the statute above-mentioned, appointed to meet at Inverkeithing. This, however, it did not long continue to do; but, like the Court of Four Boroughs and the other supreme courts of the kingdom, removed to Edinburgh as early as the time of Alexander Lord Home, who was great chamberlain from 1488 to 1517; and as that gentleman was at one time both lord provost of Edinburgh and great chamberlain of Scotland, and also, as it seems, the last in the latter office who exercised its duties in person, hence, no doubt, arose the practice of the lord provost of Edinburgh being the permanent preses, and the town-clerk of Edinburgh the perpetual clerk, of the convention. This civic parliament has continued till the present time. By stat. 1607, c. 6, letters of horning were allowed to issue on all its acts and decrees betwixt burgh and burgh, and burgesses of free burghs, on a simple charge of ten days.

FOURCHAMBAULT, a hamlet in France, department of Nièvre, and commune of Garchizy. Its extensive iron-works give employment to about 3000 hands.

FOURCHE, Bayon la, a river of the United States, in the state of Louisiana, and one of the numerous arms into which the Mississippi divides itself in the lower part of its course. Near Donaldsonville it separates from the Mississippi in the parish of Ascension, runs through that of Assumption, forms the boundary between the parishes of Terrebonne and Lafourche Intérieure, and, after a S.E. course of nearly 120 miles, falls into the Gulf of Mexico, east of the Bay of Timballier.

Fourche Grande, a river of Lower Canada, which runs through the Côte-de-la-grande-Fourche across the Temisconata Portage into the N.W. branch of the river Troispistoles.—Fourche Petite, a river, also in Lower Canada, which issues from Lake Dessangues; it also crosses Temisconata Portage, and flows into the S.W. branch of the same river, Troispistoles.

FOURCROY, Antony Francis de, a celebrated chemist and physician, born at Paris on the 15th June 1755, was the son of John Michael de Fourcroy, by his marriage with Jane Laugier. His family had been long established in the capital; several of them had been distinguished at the bar, and Fourcroy de Ramcourt was well known as an engineer of considerable talent, and a member of the Academy of Sciences.

His father was an apothecary attached to the household of the Duke of Orleans, and was a great sufferer by the abolition of places of this kind, which was procured by the corporation of apothecaries, some time before the Revolution. Young Fourcroy was sent to the college of Harcourt, but made no progress in his learning there, and underwent great hardships, from the cruelty of an unjust master. He was afterwards obliged to subsist by his labour in copying, and by taking pupils as a writing master. He was, however, fortunate in the patronage and assistance of Vicq d'Azyr, who had been a friend of his father, and under whose auspices he resolved to study physic; obtaining his support in the mean time by giving his assistance to richer persons than himself in their literary labours, and by a few translations, for which he was very ill paid. When he had gone through the regular course of study, he became a candidate for a gratuitous diploma, upon a foundation established by Dr Diest; but he failed of success, from a party quarrel. His own party, however, which was that of Vicq d'Azyr, indemnified him for the loss, by making a collection to discharge the fees, amounting to about L.250; but the highest degree, that of doctor regent, was still refused him; and he was therefore incapable of holding a professorship under the Parisian faculty of physic. He resolved to apply himself to science as the readiest way of acquiring medical reputation; but he seems to have been little known, at any time of his life, as a practical physician. The determination, however, like that of the countryman in the fable, was still a beneficial one; and though he failed of discovering the golden treasure for which he dug, he profited by the increased fertility of the soil, and by the abundant fruits which it bore him.

In natural history he soon distinguished himself as a pupil worthy of Geoffroy, by an entomological publication; and in anatomy, by his description of the tendons and their sheaths, which appears to have procured his admission into the Academy of Sciences in 1785. He stood at first in the capacity of an anatomist, though he was afterwards removed to the section of chemistry. His favourite pursuit, however, from the beginning, was chemistry; and in this he derived considerable assistance from Bucquet, who was then a professor in great esteem; and having once undertaken to deliver a lecture in his place, on occasion of a temporary indisposition of Bucquet, though wholly unprepared, he found himself capable of speaking for two hours with great fluency, to the delight and astonishment of his audience. The reputation of Bucquet was soon transferred to Fourcroy; and he was enabled, by an advantageous marriage, to purchase the apparatus of his predecessor, and to succeed to his lectures.

In 1784, upon the death of Macquer, then professor of chemistry in the Royal Garden, the Count de Buffon found the claims of Fourcroy so strong, that he thought it right to appoint him to the vacant chair, though no less a chemist than Lavoisier was a rival candidate; the competition not being wholly decided either by talent or by depth of learning, but probably, in a great measure, by the reputation in the art of teaching which Fourcroy had already acquired. His success in this new situation was brilliant and universal; and he continued for twenty-five years to absorb the whole attention of a numerous au-

dience, by his eloquence, and by the perspicuity of his mode of explaining some of the most important novelties that have ever appeared in any age. The science which he taught was then making its most rapid progress. It was then that Bergman and Scheele had introduced into analytical chemistry a precision almost geometrical; that Priestley had discovered the aëriform elements of the animal and vegetable world; that Black and Wilcke had methodised the phenomena of heat; that Cavendish had discovered the composition of water and of the nitric acid; that Monge had repeated and extended his experiments; and that Lavoisier had reduced the whole of chemistry to a uniform system, which, though founded on a generalization somewhat too hasty, has still been of important service to the science, by concentrating the attention of the philosophic reasoner on various classes of phenomena, which could not so easily have been comprehended in one view, without the aid of some such hypothesis. M. de Fourcroy was particularly happy in his tact of perceiving whether or not all his audience were fully in possession of the ideas he wished to communicate to them, and he was never tired of explaining himself, till he was satisfied that he had said enough. His manner was energetic, and such as an Englishman might perhaps have thought pompous and affected; but we must recollect that there is no fixed standard of propriety in matters of taste, and that, as the common conversation of the French is naturally accompanied with more of emphasis and gesture than our own, it is very possible that, without any greater proportional exaggeration than is introduced in similar cases in Great Britain, an actor, a lecturer, or a preacher, may exhibit what to us would appear a caricature, while it only affects his own countrymen as a natural, though impressive, style of public speaking. The chemical amphitheatre of the Public Garden was crowded by students from all countries, and from all quarters of the globe, some prompted to visit Paris by their own love of learning only, some assisted in their pursuits by their respective governments; and it was twice in succession necessary to provide more extensive accommodations for the overflowing numbers that sought for admittance.

M. de Fourcroy's political life, though not unsuccessful, seems to have contributed less materially to his happiness than his scientific career. He was chosen a supplementary member of the National Convention, and entered on the functions of the office in the dreadful period of 1793. He had, however, the wisdom to refrain from employing the eloquence that he possessed under circumstances so dangerous, and he almost entirely confined his exertions to some attempts to soften the cruel tyranny of the times. Darcet was one of the destined victims that he had the good fortune to save; but he soon found it too dangerous to persist in such interferences. M. Cuvier, however, very fully acquits him of any approbation of the judicial murders which were committed, and of any connivance at such proceedings as it might have been possible for him to avert; declaring, that if, upon the strictest inquiry, he could have discovered that there was the least foundation for charging him with having been indifferent to the fate of his great rival Lavoisier, no consideration on earth could have induced him to become the biographer of a person so odious and contemptible. It was at a later period that Fourcroy acquired some little influence as a director of the public instruction; and in this capacity he had great scope for the exertion of his talents, in the re-establishment of the many public institutions connected with science, which the madness of the Revolution had destroyed. The *Ecole de Médécine* was one of the first that was restored; but the name of Médécine seeming to carry with it too much of respect and authority for the levelling spirit of the day, the new institution was at first called *Ecole de Santé*. M. de Fourcroy was also very essentially concerned in the organization of the *Ecole Polytechnique*, as well as of the central schools of the departments, and of the *Normal* schools of Paris; nor was he an indifferent spectator of the establishment of the *Institute*, which was at first intended to be as much immediately subservient to public instruction, as to making known the results of private study. He had also considerable influence in obtaining the adoption of a law calculated greatly to facilitate the formation of a museum of natural history on a magnificent scale. If, in the pursuit of these objects, he sometimes appeared to forget the dignity of language most appropriate to his subject, it must be remembered that he lived in times when the choice of expressions was by no means at the option of the speaker. He was once denounced by the Jacobins, merely for his silence in the assembly; but he excused himself, by pleading the absolute necessity of applying himself to chemical pursuits for the support of his family.

In 1798 his duties as a senator were terminated; but he was made a counsellor of state under the consular government, and again employed in the department of public instruction, with less liberty to pursue his own ideas than before, but with more effectual means of attaining the objects of his appointment. In this capacity he directed, in the course of five years, the establishment of twelve schools of law, and of more than thirty lyceums, afterwards called royal colleges, and three hundred elementary schools; exhibiting, in the performance of this laborious duty, the greatest possible judgment and attention in overcoming the local difficulties which perpetually occurred in the details of the undertaking, and depending on none but himself for the whole of the required arrangements. He conducted himself with great impartiality in his choice of the persons to be employed, though he sometimes found himself obliged to pay a certain degree of deference to the arbitrary power under which he acted, or even to his own political connexions. Remembering the difficulties which he had himself encountered in the early part of his career, he was particularly kind and benevolent in his intercourse with those young men to whom he was the dispenser of public munificence, in admitting them to a gratuitous education.

The great number and extent of M. de Fourcroy's scientific labours may be considered as paramount to a more immediate participation in the discovery of some of the new facts which changed the aspect of the science of chemistry. His ideas were, however, often rather enlarged than profound; and he was not uncommonly somewhat too precipitate in his conclusions; but he was generally methodical in the mode of conducting his researches, and clear in relating their results. His pursuits and projects were sometimes varied a little capriciously, though he prosecuted them all with equal warmth and eloquence. He was too much the slave of public opinion for his own comfort; and even the slightest expression of censure that occurred in private society, or the most unimportant criticism that appeared in a periodical work, became a heavy misfortune to him, and deprived him of his tranquillity for a considerable time. But the desire of universal approbation acted upon him as a strong incentive to continued exertion; and, amongst all his political and official labours, he continued his experiments, his memoirs, and his lectures, with as much eagerness as if they had constituted his whole occupation. His nerves seem ultimately to have suffered by his unremitting application, and he became subject to palpitations, which, as he was well aware, rendered the duration of his life extremely preca-

rious. At last, on the 16th of December 1809, at the age of fifty-four, as he was signing some dispatches, he exclaimed suddenly, "I am dead;" and his words were true. It happened, that on that day his family were about to assemble for the celebration of an anniversary in which they were particularly interested; the assembly actually met, though only to mourn his loss; and their disappointment was rendered the greater, upon the receipt of some distinguished marks of the imperial favour, which arrived too late to be of any use to his spirits or to his health, but which would have been of the more value to him, as he had before been passed over, when some of his colleagues had received considerable gratifications. He had, however, been made a count of the empire, and a commander of the legion of honour, in addition to his various literary and scientific titles; and he must have had the heartfelt satisfaction of reflecting, that he had been of use to the promotion of knowledge by his experiments and his writings; to his country by the public institutions which he had established; and to many deserving individuals by the benefits which he had bestowed on them, without the remorse of having done injury to any one.

He left a son by his first marriage with Mlle. Bettinger, the Count de Fourcroy, an officer of artillery, who was afterwards killed in the campaign of 1813 in Saxony, and a daughter, Mad. Foucaud. By his second marriage with Mad. Belleville, the widow of M. de Wailly, he had no children. His two maiden sisters also survived him, though by no means in a state of affluence; but they received great kindness from his friend and assistant M. Vauquelin. His place at the Institute was very ably filled by M. Thénard; M. Laugier succeeded him at the Museum, and M. Gay Lussac at the Ecole Polytechnique.

The chief of M. de Fourcroy's separate publications are, *Essai sur les Maladies des Artisans*, 12. Paris, 1777, translated from Ramazzini. *Analyse Chimique de l'Eau Sulfureuse d'Enghien*, par Fourcroy et Laporte, 8vo, 1778. *Leçons Elémentaires d'Histoire Naturelle de Chimie*, 2 vols. 8vo, 1782; 5 vols. 8vo, 1789, 1794; translated by Nicholson. *Mémoires et Observations de Chimie*, 8vo, 1784; intended as a sequel to the elements. Most of these had been read to the academy before the author was a member. They relate to the metallic carbonates, to detonations, to tests for water, to combustions in a stream of oxygen, and to the properties of several saline and metallic substances. An edition of the *Entomologia Parisiensis of Geoffroy*, 2 vols. 12mo, 1780; extracted from Geoffroy's larger work, with the addition of 250 new species. *L'Art de connaitre et d'employer les Médicamens dans les Maladies*, 2 vols. 8vo, 1785. *Méthode de Nomenclature Chimique*, par de Morveau, Lavoisier, Berthollet, et De Fourcroy, 8vo, 1787. *Essai sur le Phlogistique et les Acides*, 8vo, 1788; from the English of Kirwan. *La Médécine éclairée par les Sciences Physiques*, 4 vols. 8vo, 1791, 1792; a collection of papers, with some original essays. *Philosophie Chimique, ou Vérités Fondamentales de la Chimie Moderne*, 1792, 1796, 1800. Reviewed by Deyeux, *Ann. de Chim.* lvi.; a work which has been translated into almost every European language, including modern Greek. *Procédés pour extraire la Soude du Sel Marin*, 4to, 1795. *Système de Connaisances Chimiques*, 10 vols. 8vo, 5 vols. 4to, 1800. *Rev. Ann. Ch.* xxxvi. xxxvii. Translated by Nicholson. *Tableaux Synoptiques de Chimie*, fol. 1800, 1805. *Abrégé de Chimie, pour l'usage des écoles vétérinaires. Chimie pour les Dames*, in the *Bibliothèque des Dames*.

Besides his separate works, Fourcroy was the author of more than 160 memoirs, printed in different publications, the principal of which it will be sufficient to enumerate in a very cursory manner. The most important of his later researches were published jointly in his own name and in that of his pupil Vauquelin; and it is supposed that the processes were generally conducted and often suggested by Vauquelin, but that the investigations were set on foot and directed, and the results described and methodized, with inferences and theoretical reasoning, by Fourcroy.

In the *Memoirs of the Academy of Sciences* we find an *Anatomical History of the Tendons and their Mucous Capsules*, 1785, 1786, 1787. *On the Smoking Oil of Vitriol of Saxony, and the Concrete Salt obtained from it*, 1785; modifications of the sulphurous acid. *On Hepatic Gas*, 1786. *Report on a Sand from Peru containing Copper. On Azote, and its production in animals*, 1787. *On detecting Lead in Wines*, 1787. *On Combustions in the Oxymuriatic Acid*, 1788. *On Metals precipitated by Ammonia*, 1788. *Experiments on Animal Substances, made at the Lyceum*, 1789. *On a Liver changed by putrefaction*, 1789. *On the Colours derived by Vegetables from Oxygen*, 1789. *On an Ore of Lead from Roziers*, 1789. *On the Sulphate of Mercury, and on Triple Ammoniacal Salts*, 1790. *On the Formation of the Nitric Acid by the Action of the Oxyd of Mercury on Ammonia*, 1790. *On the Combustion of Hydrogen in close vessels*, by Fourcroy, Vauquelin, and Séguin, 1790. *On Barita and Strontia*, Mém. Inst. vol. ii. 1797. *On Phosphate of Lime and on Phosphorus*, ib. *On the Urinary Secretion in Horses and in the Human Subject*, ib. *On Urinary Calculi, with two more Memoirs on the Secretion*, iv. 1803. *On the Nitrous Oxyd*, by Fourcroy, Vauquelin, and Thénard, vi. 1806. *On Cow's Milk*, ib. *On Guano, used as a Manure*, ib. *On Tabasheer*, ib. *On the Chemical Nature of Carious Wheat*, ib. *On a Detonating Substance obtained from Indigo*, ib. *On Animal Substances treated by Nitric Acid*, ib. *Two Memoirs on Crude Platina and a new Metal found with it. On the effects of Germination and Fermentation on Corn and Pulse*, vii. 1801. In the *Memoirs of the Royal Society of Medicine for* 1782–83–84, Par. 1787, we find a valuable memoir *On the Muriate of Lime*, p. 267. *On Morbid Changes in some of the Animal Fluids*, p. 488. *On the Nature of Muscular Fibres, and on the Seat of Irritability*; showing the analogy of muscular fibre to the coagulable lymph of the blood.

Many of these earlier papers have also been printed in the *Annales de Chimie*, but they are sometimes altered, and they are mixed with others which are original. *On Azote* (20), vol. i. (1789). This memoir exhibits no very favourable specimen of the author's accuracy; for he asserts in it that pure azote turns vegetable blues to green, and that it may be obtained, by means of a low heat, from the oxide of manganese. *On the Gas in the Air Vessels of the Carp. On a Morbid Change in the Blood*, ib.; exuding from the face. *On detecting Lead in Wine* (21), ib. *On two Ores of Lead*, ii. *On the action of Oxyds on Ammonia*, ib. *On the Salts of Magnesia*, ib. *On a Change in the Liver after Death* (25), iii. *On Biliary Calculi*, ib.; describing the adipocere of these substances. *On the Albumen of Vegetables*, ib. *On the Carbonate of Barita of Alston Moor*, iv. *On the Medical Properties of Oxygen*, ib. *On the Triple Salts of Ammonia and Magnesia*, ib.; an elaborate and interesting paper. *On Combustions in Oxymuriatic Acid Gas*, ib. *On the effect of Oxygen in colouring Vegetables, and on the preparation of Solid Pigments*, v. *On the Changes observed in the Cemetery of the Innocents*, ib. Fourcroy had observed that the muscular parts were often changed into a substance resembling spermaceti. *On a Black Sand from St Domingo*, vi. *On the Water of Enghein*, (2), ib. *Discoveries in Animal and Vegetable Chemistry*, ib. *On the Formation of the Nitric Acid from the Action of the Oxyd of Mercury on Ammonia*, ib. *On the Culture of Cloves in the Isle of Bourbon*, vii. *Experiments on Animal Substances made at the Lyceum in* 1790, (24), ib. *Second Memoir on the Substances found in the Cemetery. On the Cinchona of St Domingo*, viii. x.; *On the Combustion of Hydrogen*, (30), viii. *Report on Loyser's Art de la Verrerie*, ix. *On Bell Metal*, ib. The principal object of this paper is to discover a ready mode of converting the spoils of the churches into copper coin. *On Tears and Mucus*, x. *On the Sulphate of Mercury, and its combination with Ammonia*, ib.; *On the Refinement of Saltpetre*, xi. *On the Juice which furnishes Elastic Gum*, ib. *Note on the Decomposition of the Carbonic Acid Gas, effected by Mr Tennant*, xii. *On Triple Salts*, xiii. *On Animal Concretions*, from the *Dictionnaire Encyclopédique*. *On the Brain*, xvi. *Report on some Artificial Pencils*, xx. *Extract of a Memoir on Hydrocarbonous Gas, and on the supposed Combustion of Azote*, xxi. *On Detonations by Percussion*, ib. *Extract of a Memoir of Proust on Odoriferous Substances*, ib. *On obtaining Pure Barita*, ib.; an elegant and effectual process. *On the Union of Chemistry with Pharmacy*, ib. *On Vitality, and on Humboldt's Experiments*, xxii. *On the Action of the Sulphuric Acid on Vegetable and Animal Substances*, xxiii. *On the Formation of the Sulphuric Ether*, ib. *On the Sulphurous Acid*, xxiv. *Report on some Colours for Porcelain*, xxv. *Letter to Humboldt on the Chemistry of Life*, xxvii. *Examination of Dr Pearson's Experiments on Calculi*, ib. *On Pneumatic Medicine*, xxviii. *On the Experiments of Mayow*, from the *Dictionnaire Encyclopédique*, xxix. *Novelties from Egypt*, ib. *On Congelation by Artificial Cold*, ib. *Letter to Giobert on Calculi*, xxx. *Notice of Venténat's Vegetable System*, ib. *On the Chemical and Medical History of the Urinary Secretion*, xxxi. xxxii. His investigations respecting calculi, however, notwithstanding their importance, were in a great measure anticipated by Wollaston, whose paper, however, is not mentioned by M. de Fourcroy. *Notice of the Chimie Optematique*, xxxi. *Account of a Memoir of Fabroni on Fermentation and on Ether*, ib. *Chemical Novelties*, xxxii. *Report on Paul's Artificial Waters*, xxxiii. *On Dabit's Ether*, xxxiv. *On the Identity of the Three Empyreumatic Acids with the Acetic*, xxxv.; suggesting that they might be substituted for it in some economical processes. *Galvanic Experiments*, xxxix; by Fourcroy, Vauquelin, and Thénard. *Note in Answer to Proust*, xlii. *Remarks on a Memoir of the Dutch Chemists on the Carbonic Oxide*, xliii. *On a New Phosphate*

found in the Bones, xlvii.; that of magnesia, not before observed. *Extract of a Memoir on Platina*, xlviii. *Two Memoirs on Crude Platina, and on a Metal found with it*, xlix. l. *Extract from Izarn's Manual of Galvanism*, l. *On the Alumina of Saxony*, lii. *On a Fluid found in the Caoutchouc of the Castilloya Elastica*, lv. *On a Denonating Substance formed by the Action of the Nitric Acid on Indigo and Animal Matters*, lv.; the investigations relating to indigo have since been carried further by Mr Hatchett. *On the Products of Animal Substances treated with the Nitric Acid.* lvi. *On the Guano* (39), lvi. *Experiments on Ivory, Recent and Fossil, and on the Enamel of the Teeth, in search of the Fluoric Acid*, lvii.; these experiments were not completely successful, though the fluoric acid had been detected by Morichini in the teeth before that time, and by Berzelius more recently.

M. de Fourcroy was for some years the editor of the *Journal des Pharmaciens*; he first suggested the idea of the publication of the *Annales du Muséum d'Histoire Naturelle*, and contributed several valuable papers to it, as well as to the *Journal de l'Ecole Polytechnique*, and to the *Magazin Encyclopédique*. He was also the author of some very voluminous articles in the chemical part of the *Encyclopédie Methodique*; but the fabric of his celebrity is principally founded on the works which have already been enumerated.

(Palissot de Beauvois, *Eloge Historique*, Par. 1810; Cuvier, *Eloge*, M. Inst. A. Math. 1810, and in Biographie Universelle, xv. 8. Par. 1816; Thomson's *Annals*, i. May 1818, p. 321; Aikin's *General Biography*, vol. x. 4to, Lond. 1815.) (T. Y.)

FOURIER, Charles, the celebrated French sociologist was born at Besançon in 1772, and died at Paris in 1837. A detailed account of his life with an analysis of his doctrines is given under the article Communism, vol. vii. pp. 209-210.

FOURMONT, Etienne, professor of the Arabic and Chinese languages, and one of the most learned men of his time, was born at Herbelai, near Saint Denis, about four leagues from Paris, in 1683. He studied in Mazarin College, and afterwards in the Seminary of Thirty-three. He was at length appointed professor of Arabic in the Royal College, and admitted a member of the Academy of Inscriptions. In 1738 he was chosen a member of the Royal Society of London, and in 1741 a member of that of Berlin. He was often consulted by the Duke of Orléans, first prince of the blood, who had a particular esteem for him, and made him one of his secretaries. Fourmont was the author of many learned works, the most important of which are—*Racines de la Langue Latine mises en vers François*, Paris, 1706, in 12mo; *Réflexions Critiques sur les Histoires des Anciens Peuples*, Paris, 1735, in 2 vols. 4to; *Meditationes Sinicæ*, 1737, in folio; *Grammatica Sinica* (Chinese Grammar), 1742; and several Dissertations printed in the *Mémoires de l'Acad. des Inscriptions*. Fourmont died at Paris on the 18th December 1745, at the age of sixty-two. He must not be confounded with *Michel Fourmont*, his youngest brother, who was professor of the Syriac language in the Royal College, and a member of the Academy of Inscriptions, and who died in 1746.

FOURNESS, or Furness, a tract of land in Lancashire. See Lancashire.

FOU TCHOW FOU, or Fuhchau Fu, a city of China, capital of the province of Fo-kien, and one of the five ports recently opened for commerce, stands on the N. side of the Min river, 34 miles from its mouth, and 9 from Pagoda island, where ships anchor. N. Lat. 26. 5.; E. Long. 119. 20. The walled city is about 3 miles from the river, but extensive suburbs stretch along both its banks. They are connected with each other, and with a small islet in the river by a stone bridge 420 paces long, lined with shops, and resting on solid stone piers, 40 on the northern, and 9 on the southern side. Several lookout houses are placed over the streets, or upon the roofs of buildings, one of which immediately attracts the attention of the visitor from its height, and its clock-dial with Roman characters. Few vacant spaces occur within the walls of the city, which is everywhere equally well-built. Serpentine canals divide the country around into plats of greater or less extent, and help to drain the city, as well as provide channels for boats to come up from the river. These parts of the landscape are dotted with hamlets and cottages, or, where the ground is higher, with graves and tombstones. The maritime commerce of this city is very considerable, and its manufactures of cotton goods and porcelain ware are extensive. The population of Fou Tchow Fou and suburbs, is estimated at about 600,000.

FOWEY, a decayed seaport, borough, and market-town of England, county of Cornwall, at the mouth of a small river of the same name, 11 miles S.S.E. of Bodmin. The town is surrounded by scenery of great beauty, but it is irregularly built, and the streets are very narrow and full of angles. The inhabitants are engaged chiefly in the catching and curing of pilchards. The harbour is safe and commodious, and is defended by an ancient and two modern forts. Previous to the Reform Act by which it was disfranchised, it returned two members to parliament. This town became famous in the old French wars, and in 1347 sent 37 tall ships to the siege of Calais. It was burned by the French in 1457. Pop. of parish (1851) 1606.

FOX, in *Zoology*. See index to Mammalia.

FOX, Charles James, a celebrated statesman and orator, was third son of the Right Honourable Henry Fox, afterwards Lord Holland, and of Lady Georgina Caroline Fox, eldest daughter of Charles, second Duke of Richmond. He was born on the 24th January 1749.

Mr Fox received the first rudiments of his education in a private school of some celebrity, kept by a Mr Pampelune at Wandsworth. In 1758 he was sent to Eton, where he gave early promise of future eminence. In the beginning of summer 1763 the mistaken indulgence of his father carried him first to Paris, and then to Spa. After wasting idly three months abroad, he was sent home to England, and at his own desire he went back to Eton He had left school a boy; he returned to it with all the follies and fopperies of a young man. At Spa he had been initiated in play; and his father, whose fondness for him was excessive, had encouraged him in a propensity which was the source of much future unhappiness to both.

In the autumn of 1764 he was removed from Eton and sent to Oxford, where he was placed at Hertford College, under the tuition of Dr Newcome, afterwards primate of Ireland. At Oxford as well as at Eton he distinguished himself not less by his powers of application than by the quickness and superiority of his parts. The following letter, which he preserved with care, and used to show with triumph when reproached for idleness, is a curious document of his diligence in study while he was at college. "You judge rightly," says Dr Newcome in a letter to his pupil, "in thinking that I should be much surprised by the information which you were so obliging as to give me. But, on reflection, I think you have done well to change the scene in such a manner, and I feel myself inclined to envy you the power of doing it. Application like yours requires some intermission; and you are the only person with whom I have ever had connection to whom I could say this. I expect that you will return with much keenness for Greek, and for lines and angles. As to trigonometry, it is matter of entire indifference to the other geometricians of the college (who will probably continue some time here), whether they proceed to other branches of mathematics immediately, or wait a term or two longer. You need not, therefore, interrupt your amusements with severe studies; for it is wholly unnecessary to take a step onwards without you, and therefore we shall stop till we have the pleasure of your company. All your acquaintances here whom I know are well, but not much happier for your absence." This letter was probably written in spring 1765, when Mr Fox made a second excursion to Paris with his mother.

In autumn 1766 he quitted Oxford, and accompanied

his father and mother to the south of Europe, where Lord Holland had been advised to pass the winter on account of his health. He remained with them at Naples during the winter, and not finding a good Italian master there, taught himself that language. In the following spring he attended them as far as Turin in their way to England, and then went to Genoa to meet Lord Fitzwilliam, with whom and Mr Uvedale Price he spent the summer in Italy, chiefly in Tuscany. In the beginning of winter he rejoined his father and mother at Paris, and accompanied them to Nice, where he passed with them the winter of 1767–68. It was during this long residence in Italy that he contracted his strong partiality for Italian literature. In a letter to Mr Fitzpatrick, written from Florence in September 1767, he conjures him to learn Italian as fast as he can, if it were only to read Ariosto. "There is more good poetry in Italian than in all other languages I understand put together." He appears to have indulged freely at this period in all the pleasures natural to his time of life, but never to have intermitted entirely his application to study. *Je travaille toujours le matin*, he says, in another letter written from Nice. Acting plays was also at this time one of his favourite passions, though he confesses that the last time he acted he fell far short of his own expectations; "but then," he adds, "my expectations, it must be confessed, were very high." In the course of this journey he made a visit to Voltaire at Fernay, in company with Mr Price.

He did not return to England till August 1768; and having been elected one of the burgesses for Midhurst in his absence, he took his seat in the ensuing session, and made his first speech in the House of Commons on the 15th of April 1769, in support of the decision in favour of Colonel Luttrel, on the famous Middlesex election. He spoke, says Horace Walpole, with insolence, but with infinite superiority of parts.

Lord Holland, father to Mr Fox, had begun his political career as an adherent of Sir Robert Walpole, and continued ever after one of the steadiest friends and warmest admirers of that great statesman. The treachery of the Pelhams to his patron excited an early prejudice in his mind against all the members of that family; and the falseness, folly, and fickleness of the Duke of Newcastle added contempt and distrust to his dislike. After a long rivalship with Mr Pitt, he was finally driven from the cabinet by a coalition of the Pitt and Newcastle parties, and reduced to the subordinate though lucrative employment of paymaster of the forces. In this situation he was found by Lord Bute at the conclusion of the war, and recommended to the king as the only person in the House of Commons who had courage and ability to defend the peace against Mr Pitt and the Newcastle party. It was with great difficulty he was prevailed on by his majesty to undertake this office, but when engaged in it, he performed it most successfully. For his services on this occasion he was rewarded with a peerage; but the part he had taken estranged him for ever from his old friends the Dukes of Cumberland and Devonshire, and other leaders of the Whig party. It was at this period that his son Charles received his first political impressions; and there is still extant a copy of French verses written by him in 1764, in praise of Lord Bute, and full of invective against Mr Pitt. When brought into parliament, he was, therefore, in the first instance, connected with the Duke of Grafton's administration, which, though originally formed under the auspices of Lord Chatham, had been gradually sinking into a mere court party.

Mr Fox was not of age when returned to parliament, and probably for that reason, after his first speech, he took little part in public debate till January 1770. During this interval he made another excursion to the Continent, where he is chiefly taken notice of for his losses at play. He had, as already mentioned, acquired a passion for play as early as his first journey to Spa; and for many years afterwards, when not engaged in active political business, play and Newmarket were his chief avocations. His losses were such as early to embarrass, and finally to ruin, his private fortune; but so great a hold had these pursuits taken of his mind, that, till the payment of his debts in 1794, he could never prevail on himself to renounce them entirely. From that moment he gave them up for ever.

In February 1770 he was rewarded for his support of government with the place of junior lord of the admiralty, which he retained for two years, and resigned on the 20th of February 1772, partly in consequence of some slight offence he had received from Lord North, and partly because he had resolved to oppose the royal marriage bill, "which, *in place*," he says, "I should be ashamed of doing;" but he had no thoughts, he adds, "of going into opposition." He had an immediate and satisfactory explanation with Lord North; but, to punish him for his speech against the royal marriage act, which was a measure entirely the king's own, he was suffered to remain a considerable time out of office. At length, in January 1773, he was made one of the lords of the treasury, a situation he continued to fill till his memorable quarrel with Lord North in the following year.

Some gross and scandalous reflections upon the speaker of the House of Commons, written by the celebrated Horne Tooke, having appeared in the Public Advertiser, Mr Woodfall, the printer of that newspaper, was called to the bar of the house, and having there confessed himself publisher of the libel, he was declared guilty of a breach of privilege; on which Mr Herbert moved that he should be taken into the custody of the serjeant-at-arms. The house, unwilling to engage in a fresh contest with the press and the city, were disposed to acquiesce in this motion; but Mr Fox, thinking the punishment inadequate to the offence, without consulting Lord North, moved, as an amendment, that Mr Woodfall should be committed to Newgate. Lord North found himself compelled by this motion to resist Mr Herbert's proposition; but though he substituted the Gatehouse for Newgate, as a less objectionable place of confinement, he was left in a minority on the division, the original motion being carried by a great majority. Incensed at this disgrace, and determined to punish his youthful colleague for his temerity, he had a new commission of the treasury made out a few days afterwards, in which the name of Mr Fox was omitted. This happened in February 1774.

Long before his breach with Lord North, Mr Fox had formed an intimate acquaintance with Mr Burke, one of the leading members of the Whig or Rockingham party in the House of Commons; and to the friendship he contracted with that gentleman may, in a great measure, be attributed the decided change in his political character and opinions, which commenced at this time. He had been brought up by his father in the maxims and principles of Sir Robert Walpole; and from this education he derived the love of peace, the good-humoured spirit of conciliation, and ardent attachment to civil and religious liberty, which were afterwards the most conspicuous features of his public character, and are certainly the chief merits of the Walpole school. But the tone and character of Sir Robert Walpole's policy, though suitable, and perhaps necessary, for the times in which he lived, was no longer adapted to the state of the country. When the Jacobites renounced their idol without changing their creed, and transferred to the house of Brunswick the same allegiance

which they had borne to the Stuarts, the weapons which Sir Robert had employed to preserve the constitution became, in the hands of its enemies, instruments of its destruction. Mr Burke was the first to perceive, or at least the first to explain, the change that had taken place in our internal government, and the first to point out a plan of systematic opposition in parliament, as the only means of preventing, or at least of retarding, what Mr Hume has called the *euthanasia* of English liberty. In Mr Fox he found a pupil ready to receive his lessons, and prepared by character and turn of mind to act upon them with fortitude and perseverance. From Mr Burke's example and instructions Mr Fox caught more elevated notions of public principle than had animated the successors of Sir Robert Walpole; and from the writings and conversation of the same great man he learned the necessity of party connections in a mixed government like ours, to counteract the influence of government, and preserve a due balance of power between the crown and the people. The American war roused all the energies of his mind. The discussions to which it gave rise involved all the first principles of free government. The vicissitudes of the contest tried the firmness of its opponents. Its duration exercised their perseverance. Its magnitude and the dangers of the country called forth their powers. The progress of Mr Fox was steady and uninterrupted. So early as the beginning of 1775, we are told by Gibbon that "he discovered powers for regular debate, which neither his friends hoped nor his enemies dreaded."

But, notwithstanding the brilliancy of his talents and the reputation he acquired in the House of Commons, the levity and want of decorum of his private life, the dissipation in which he indulged, and the embarrassments in which he was involved, prevented him, for some years, from obtaining the weight and consideration with opposition, due to his extraordinary abilities and exertions. So late as the beginning of 1778 he was under no engagements with any set of men; but, though not absolutely engaged in party connections with the Whigs, he had determined on no account to abandon their principles; and from a cool consideration of his own character, and a just conception of the prevailing sentiments of the country, he had already fully made up his mind to the fate that ultimately awaited him. "People flatter me," he says in a letter to Mr Fitzpatrick, written in 1778, "that I continue to gain rather than to lose character as an orator; and I am so convinced this is all I ever shall gain (unless I chuse to be one of the meanest of men), that I never think of any other object of ambition. I am certainly ambitious by nature, but I have, or think I have, totally subdued that passion. I have still as much vanity as ever, which is a happier passion by far, because great reputation, I think, I may acquire and keep; great situations I never can acquire, nor, if acquired, keep, without making sacrifices that I will never make. If I am wrong, and more sanguine people right, *tant mieux*, and I shall be as happy as they can be; but if I am right, I am sure I shall be happier for having made up my mind to my situation." He expresses great joy at the prospect of Fitzpatrick's return, who he knew would be of his opinion in certain emergencies that might arise. "I shall be told by prudent friends that I am under no sort of engagements to any set of men. I certainly am not; but there are many cases where there is no engagement, and yet it is dishonourable not to act as if there was one. But even suppose it were quite honourable, is it possible to be happy in acting with people of whom one has the worst opinion, and being on a cold footing (which must be the case) with all those whom one loves best, and with whom one passes one's life?" With these sentiments it is not to be wondered at that he rejected overtures made to him by Lord Weymouth, in summer 1778, to join administration; nor, with his powerful talents and unremitted exertions, the inflexible steadiness of his public conduct, and the unexampled force and vehemence of his eloquence, that he gradually acquired the perfect confidence of the Whigs, and came at length to be considered as the leading member of the Rockingham party in the House of Commons. It ought to be recorded to the credit of Mr Burke, that he witnessed with pleasure, unmixed with envy, the progress and elevation of his pupil, and cheerfully resigned to him the station he had so long himself occupied in the party.

The day of triumph at length arrived. A resolution against the further prosecution of the American war was carried in the House of Common. Ministers still lingered in office, but the fears of a direct vote of censure compelled them to resign. The king, whose pertinacity in support of his favourite principles of government had been the chief if not the sole cause of the apparent reluctance of his ministers to retire from office, was compelled at length to yield to the wishes of his Commons; but in the very act of forming a new administration, he contrived to sow the seeds of disunion in its bosom. The opposition to the American war had been composed of two parties, united in their disapprobation of that contest, but disagreeing on many other points of external as well as of internal policy; both calling themselves Whigs, but Whigs of different schools; the one consisting of the old Whig connection, formed and educated in the principles of Mr Burke; the other composed of the friends and followers of Lord Chatham. At the head of the first was the Marquis of Rockingham, whilst the leader of the second was the Earl of Shelburne. His majesty began by sounding Lord Rockingham, through the chancellor. The demands of Lord Rockingham were, to have full power to recognise the independence of America, and authority to bring forward, as ministerial measures in parliament, bills for reducing the influence of the crown, by abolishing offices, excluding contractors from the House of Commons, and depriving revenue officers of their votes at elections; and, with respect to reform in the representation, or limitation of the duration of parliament, he declined to lay himself under restrictions. After taking time to consider this answer, his majesty sent for Lord Shelburne, and had a conference with him at Buckingham house. Two days afterwards he sent for him again, and offered him the treasury, which his Lordship declined, saying that no administration suited to the present emergency could be formed unless Lord Rockingham was at the head of it; on which the king desired him to go to Lord Rockingham with an offer of the treasury, and to add, that he had full powers from his majesty to treat both with respect to men and measures, with one reservation only, that he should himself be one of the secretaries of state. The first impulse of Lord Rockingham was to decline this offer, upon the ground, that if it was the king's intention to place him at the head of the treasury, his majesty could have no fit objections to conversing with him on the arrangement of the administration; but his friends persuaded him to overlook that objection, lest his refusal should be ascribed to pique or jealousy, at a moment when the public was extremely impatient for the formation of a government. Many fatal consequences ensued from the negotiation taking this course and passing through the hands of Lord Shelburne. No direct communication took place between the king and the Rockingham party, who were to compose the majority of the cabinet, with respect to the measures to be pursued, till after the administration had been formed. Lord Thurlow, a decided partisan of the old system, and an enemy to every species of reform, was retained as lord

chancellor; Mr Dunning having been prevailed upon by his friend Lord Shelburne to waive his pretensions to that office. When this arrangement was communicated to Mr Fox, he told Lord Shelburne plainly, "that he perceived the administration was to consist of two parts, one belonging to the king, the other to the public." But the worst effect of all was the impression left on the mind of Lord Shelburne, that he alone possessed the confidence of his sovereign, to the exclusion of his colleagues. This persuasion bred distractions in the cabinet, which soon became a theatre of dissension and open division; and these divisions, whispered about, weakened the government whilst it lasted, and contributed materially to its fall.

Of this short-lived administration, the principal measures were the pacification of Ireland and the bills for economical and parliamentary reform, which, though short of the public expectation, are still the most important acquisitions of that description obtained since the accession of the house of Hanover. The death of Lord Rockingham dissolved the ministry over which he presided. The treasury was immediately offered to Lord Shelburne, on pretence that, having refused it before, it naturally devolved on him on Lord Rockingham's death. His acceptance of it destroyed the former balance of parties in the cabinet, and overset entirely the balance of power in the government. Accordingly Mr Fox and Lord John Cavendish immediately resigned, and, after some interval, they were followed by Lord Keppel. The Duke of Richmond and General Conway remained in office; the latter from simplicity, the former from dissatisfaction at seeing the Duke of Portland preferred to himself as leader of the Whig party. The other members of the cabinet were friends of Lord Shelburne.

Mr Fox has been severely blamed for his precipitancy on this occasion; and, though his resignation was a measure that could not long have been deferred, the time at which it took place makes it perhaps liable to that imputation. It followed so immediately the appointment of Lord Shelburne to the treasury, as to have the appearance of being the result of disappointed personal ambition, rather than of any difference on public grounds. It reduced his friends who were in office to the alternative of immediately following his example, or of passing for adherents of Lord Shelburne; and, as the whole of his motives could not at that time be explained in public, it gave an opportunity to the Duke of Richmond and others to keep their places without forfeiting their characters. It took place at the close of a session of parliament, and left Lord Shelburne and the court for six months in undisturbed possession of the government. It was a cruel disappointment to the public, which had expected a firm and united administration on the principles of those who had opposed the American war and the system that gave rise to it. But to those who judged rightly, the elevation of Lord Shelburne to the treasury was the utter extinction of these hopes. The Rockingham party had found in Lord Shelburne an active and spirited ally in opposition; but they had never been confidentially united with him; and though ready to co-operate with him in a subordinate office, they were not prepared to act under him as premier. It was not the impatience and dissatisfaction of Mr Fox alone that broke up the administration. As soon as the appointment of Lord Shelburne to the treasury was known in Dublin, the Duke of Portland determined to resign his office of lord-lieutenant of Ireland. Lord John Cavendish could with difficulty be prevailed upon to postpone his resignation for a few days. Mr Burke urged strongly to Mr Fox the impossibility of his remaining long in office as a clerk under Lord Shelburne; and it must be owned that, in the subsequent treatment of his colleagues, that nobleman fully justified the apprehensions then entertained of his future conduct. Elated with the fancied possession of court favour, he from that time forward treated the other ministers as mere ciphers; made additions to his cabinet without consulting or even apprising them of his intentions; and is even said to have settled and concluded the terms of his peace with France, without the advice or participation of his secretaries of state.

There were, besides, before the death of Lord Rockingham, differences of such importance in the cabinet as must have led to a dissolution of the administration. It was the policy of Mr Fox to detach Holland and America from their unnatural connection with France; and the great object of his foreign politics was, to form a continental alliance as a balance against the house of Bourbon. The system of Lord Shelburne was to conciliate France, to cultivate a confidential understanding with her government, and to treat her allies as so many inferior and dependent powers. Mr Fox had recommended and carried in the cabinet (23d May 1782) a resolution to instruct Mr Grenville, his majesty's plenipotentiary at Paris, to propose the independence of America in the first instance, instead of making it a condition of a general treaty; and this offer, to which his majesty's consent had been obtained, was actually communicated by Mr Grenville to Dr Franklin. Lord Shelburne, though obliged to acquiesce in the determination of the cabinet, endeavoured afterwards to represent the offer as only conditional, to be recalled if not accepted as the price of peace; and this explanation having been adopted by a majority of the cabinet after the illness of Lord Rockingham, Mr Fox declared his determination to resign. The discovery of a mysterious negotiation at Paris contributed to strengthen this resolution. It was a great object with Mr Fox, in pursuance of his system of policy, to open a free and unreserved communication with Dr Franklin. Through Mr Grenville he had hoped to accomplish this design, and he had nearly succeeded in his purpose, when he had discovered, to his infinite surprise and indignation, that Lord Shelburne had been carrying on a clandestine intercourse with Franklin through Mr Oswald, and had received from him and made to him important communications, which had not been imparted to his colleagues. This discovery, which was made before Lord Rockingham's death, destroyed all confidence in Lord Shelburne among the friends of that nobleman, though, from the delicate nature of the transaction, it was impossible at the time to make it the subject of public animadversion, or even allusion.

The resignation of Mr Fox and his friends compelled Lord Shelburne to strengthen his government from every quarter where support could be obtained. Mr Pitt, who had declined accepting a subordinate office in the Rockingham administration, became his chancellor of the exchequer. Rigby, Dundas, and Jenkinson, old supporters of the American war, attached themselves to his train. A negotiation was opened with the remaining partisans of Lord North, which only failed of success in consequence of Mr Pitt, with more judgment than feeling, making personal objections to Lord North himself, which wounded the pride, and excited the indignation, of his friends and family. When parliament met after the signing of the preliminaries of peace, there were three parties, nearly of equal strength, in the House of Commons; that of the minister, reinforced by the court, and several of the most objectionable members of Lord North's administration; the Rockingham party, who had gone into opposition with Mr Fox; and, lastly, Lord North and his friends. That three separate parties, so equally balanced, should continue to act in the House of Commons without some coalition, was not to be expected. A re-union of the

Whigs would have been most acceptable to the public; but recent differences, mutual recriminations, and distrust of Lord Shelburne, rendered such a coalition impracticable. The personal objections, so harshly and acrimoniously stated, against Lord North, had exasperated his friends against the ministry. Nothing, therefore, remained but a junction of the two parties in opposition; and this coalition, which time would naturally and imperceptibly have brought about, was hastened and matured by the coincidence of their opinions against the peace. The first step was to concert an amendment to the address of thanks on the preliminary articles signed at Versailles; and this amendment was carried in the Commons by a small majority, but not without great indignation being expressed in the house, and a violent outcry raised out of doors, at the apparent junction of the two parties. No coalition had yet taken place. Lord North was still at liberty to have formed an administration without Mr Fox; and it was the opinion of one of the most judicious friends of the latter, that to undertake the government with Lord North, "was to risk their credit with the public on very unsafe grounds." On the part of the Whigs there seems to have been a momentary hesitation whether to proceed farther or to step back. "Unless a real good government is the consequence of this junction," says one of the most sagacious of the party, "nothing can justify it to the public." "There never was a case of more difficulties and dangers to the real friends of whiggism and good principles." The die was at length cast; and in an evil hour, if we are to judge, not from principles, but from results, the coalition was effected. The united strength of the two parties procured a vote of censure on the peace. Lord Shelburne, who still flattered himself with the possession of court favour, is said to have proposed an immediate dissolution of the parliament. But he had served his turn, and was no longer wanted. His majesty judged rightly, that the time was not yet come for so bold a measure, and allowed his minister to resign.

A long interval ensued before the coalition administration was formed. Repeated attempts were made to detach Lord North from Mr Fox; and when these had failed, it was stated as an indispensable preliminary to any ministerial arrangement, that Lord Thurlow should be continued as lord high chancellor. But the fatal effects of a secret enemy in the cabinet had been too severely and too recently felt to concede a point of so much importance. A complete change of administration was insisted upon, and was granted at last, but with the worst possible grace, and with every symptom of ill humour and dissatisfaction. It was not merely the triumph of the coalition that filled the royal bosom with such indignation. His majesty considered the Rockingham party as enemies to his just prerogative. Nor could he forgive them for their zeal against the American war, and inflexibility, when they came into office, in insisting on the unconditional acknowledgment of American independence. "The extraordinary and never to be forgotten vote of February 1782, and the hurry for negotiation that after ensued," had, in his opinion, lowered the spirit of the country, and given confidence to its enemies; and in his own mind had produced such indifference on political subjects, that he felt no anxiety for the arrival of the definitive treaty, or concern for the delays that retarded its conclusion. When it was suggested to him that a wish on his part to receive a minister from America would be favourably received in that country, and might tend to preserve peace and restore harmony in future, he is said to have replied with bitterness, that to receive a minister from America, he could never say would be agreeable to him; and that he should ever have a bad opinion of any Englishman who could accept being an accredited agent to that revolted state. With such feelings rankling in his mind, is it to be wondered at that his majesty was hostile to an administration, the majority of which had zealously concurred in the grant of independence to America?

The coalition ministry was hardly settled, when a misunderstanding arose about the establishment of the Prince of Wales; and so skilfully had the affair been managed on the part of the king, that if his royal highness had not submitted entirely to his father's pleasure, the administration must have been overturned almost as soon as formed. But though no change was attempted before the meeting of parliament, his majesty contrived on every occasion to show ill humour to his ministers, and no one in a situation to observe could doubt for a moment that he only waited for a favourable opportunity to turn them out. The India bill afforded such opportunity. That measure was represented as an invasion of chartered rights, as the establishment of a ministerial oligarchy, independent both of prince and people. The nation, disgusted and offended at the coalition, listened with credulity and favour to these accusations. The king, who had carefully disguised his sentiments to the last moment, procured the rejection of the bill in the Lords, through the agency of Lord Temple, and instantly dismissed his ministers.

The coalition ministry was at an end, but its leaders still possessed the confidence of the House of Commons. The cry of secret influence was raised, and more violent addresses carried to the throne than had ever been presented to any prince of the house of Brunswick. Lord Temple, who had accepted the seals, grew frightened at the storm he had raised, and gave in his resignation. Even Mr Pitt became alarmed in the progress of the contest; and the firmness of the Duke of Richmond alone prevented him from following the example of his kinsman. But, as the struggle proceeded, the voice of the people was every day more unequivocally declared in support of the new administration. Courtiers and reformers, churchmen and dissenters, squires and nabobs, joined in execrating the coalition and applauding the minister, in professions of attachment to the king, and declarations of hostility to the Commons. After the attempt of the country gentlemen to make a new coalition of parties had failed, the majorities of opposition began to diminish; and when some necessary votes had been obtained, this refractory House of Commons was punished by a premature dissolution, for its want of subserviency to the crown.

Our limits will not permit us to follow with the same minuteness the political life of Mr Fox in the subsequent parts of his public career. From 1784 to 1792 he was leader of a powerful party in the House of Commons, in opposition to Mr Pitt. His most remarkable exertions during that period were against the Westminster scrutiny, on the regency, against the abatement of impeachments by a dissolution of parliament, on the libel bill, and on the Russian armament. He never published nor corrected any of his speeches, except the one on moving a new writ for the borough of Tavistock; and of those which appeared in the newspapers, and have since been collected, his speech on the scrutiny is the only one so well reported as to give the reader an adequate notion of his style of speaking. It failed at the moment in procuring justice for the Westminster electors; but the impression it made on the house was such, that in the following year an end was put to that odious and vexatious piece of chicanery, worthy of the pettyfogging genius of its inventor, but disgraceful to the minister who gave it his countenance and support. We have not room to discuss at length the regency question. The case was new and unprovided for.

There was no direct precedent, nor legal authority in the kingdom to make one. Constitutional analogy pointed out the heir-apparent as the fittest person to exercise the royal authority during the indisposition of the king; and the same analogy indicated the great council of the realm as the body most competent to declare the incapacity and apply the proper remedy. Strict or legal right there was none on either side. The prince had no legal right to the regency; nor till they chose to declare it themselves, had the two houses of parliament any legal right to elect a regent, or to fetter him, previous to his election, with restrictions. The contrivance to create, first a phantom, and then a regent, was a clumsy piece of machinery, nearly allied to treason. The claim of right advanced for the prince was a flimsy speculation of Lord Loughborough, adopted on his authority, without due examination, by Mr Fox, who returned in haste from Italy, while the discussions on the regency were pending. As explained afterwards, the doctrine, if not true, was at least harmless. But the opportunity was skilfully laid hold of by the minister, for the purpose of making his rival unpopular, and of gaining time for the king's recovery, which Addington, who had great experience in such maladies, assured him, from the beginning, would certainly take place. In his argument against the abatement of impeachment by a dissolution of parliament, Mr Fox had the support of Mr Pitt, and never was a more triumphant reply than his answer to the arguments on the other side. Of the libel bill it is unnecessary to say a word. The country still profits by it, and regards it as a most important security to our constitutional freedom. By his exertions on the Russian armament, he had the satisfaction to save his country from at least one unnecessary, unjust, and expensive war. We must hasten to an occasion where his efforts were less successful.

The beginning of the French revolution gave universal satisfaction to the friends of liberty in this country. Soon after the taking of the Bastille, Mr Fox describes it "as the greatest, and much the best event that ever happened in the world;" and adds, "all my prepossessions against French connections for this country will be at an end, and indeed most part of my European system of politics will be altered, if this revolution has the consequence that I expect." When the king of France was brought back from Varennes, a report having been circulated in England that it was the intention of the national assembly to bring the queen to trial for her life, he composed a letter to Barnave, one of the leading members of the assembly, with whom he was personally unacquainted, exhorting him against such a measure of useless cruelty, which could not fail to bring disgrace on the cause of liberty. The letter was never sent, in consequence of the report proving to be unfounded; but we subjoin some extracts from it, in order to show the spirit in which it was written. After an apology for obtruding his advice on one who was unknown to him, except by reputation, and stating the bad impression that any unnecessary severity to the queen would produce in England; after praising the assembly for the firmness they had displayed on receiving the news of the king's escape, and urging them to show as much clemency and moderation in prosperity, as they had manifested coolness and resolution in danger; after stating the argument for sending the queen out of the country, or, at most, for confining her in a place of security, he proceeds as follows: "De l'autre coté, si on la juge cette malheureuse femme, qu'on la condamne, et qu'elle subisse son sort, je ne sais que trop bien que ce seraient les ennemis de la liberté qui en triompheront. On la peindra cette liberté comme feroce et cruelle, on tachera de la rendre odieuse, et parmi les âmes faibles on ne reussira peut-etre que trop bien. Le despotisme a toujours eu l'addresse de se servir des passions des hommes pour les subjuguer. Il a eu à ses gages la superstition et l'intérêt personnel, et il seroit bien facheux que la pitié, la plus aimable de toutes les faiblesses humaines, se rangeât aussi de son coté. Je ne sais si je me trompe, mais il me parait que vous êtes precisément dans la position où vous pouvez faire une action belle et genereuse sans le moindre danger; c'est-à-dire, que vous êtes dans la prosperité la moins equivoque. Vous avez donné par vos travaux la liberté à votre patrie, et vous trouvez dans elle une recompense aussi touchante que juste. Travaillez actuellement pour le genre humain, et faites aimer la liberté à toutes les nations de la terre, en prouvant qu'elle nourrit dans l'âme non seulement les vertus mâles comme le courage et la justice, mais aussi la douceur, la moderation, et la clemence." Such were the sentiments and conduct of a man, who was afterwards represented to his countrymen as the blind apologist of all the horrors of the revolution, and indifferent spectator of the calamities of the royal family of France.

As the revolution departed from its original character of justice and moderation, its favourers in this country began to fall off. Mr Burke, scandalized at the confiscation of church property, was the first of the Whig party to declare against it. His violent and outrageous quarrel with Mr Fox in the House of Commons is too well known to need to be here related. No event of his life had ever given such unfeigned sorrow to Mr Fox, as this breach with his old friend and political instructor. But he had soon many other losses of the same sort to deplore. The excesses of the revolution, the democratic form it assumed, the fear lest its example should prove contagious in England, filled with alarm the older, richer, and more aristocratic members of the Whig party. Younger and more ardent spirits, looking to the goodness of the cause, disregarded the unfitness of the instrument used to promote it; and, exulting in the progress of political freedom abroad, thought the occasion favourable for extending and enlarging our constitutional rights at home. A schism was gradually formed in the Whig party, which the formation of the Society of the Friends of the People, and the royal proclamation in May 1792, brought to a public explosion. Mr Fox was eagerly courted on both sides; but if he appeared to hesitate, it was only to keep his friends, if possible, together, and prevent a permanent separation, which he foresaw would invest the minister, as it did, with absolute power. But the revolution of the 10th of August, the massacres of September, the success of the French arms under Dumourier, the violence and indiscretion of the friends of reform at home, spread a panic terror over the land; and the minister who had trifled and temporised till it was too late, found himself unwillingly forced into a war, which he had not wisdom to avert or genius to conduct.

We cannot follow Mr Fox in his opposition to this disastrous war, nor in his subsequent efforts for the restoration of peace. On no occasion was the vigour of his intellect, the sagacity of his foresight, the firmness and resolution of his character, more conspicuous than during the struggle he maintained against overwhelming majorities from 1792 to 1797. Till the Duke of Portland, and other alarmists of the Whig party, joined administration in 1794, he always flattered himself with the hope of renewing his connection with his old friends, when their fears should have subsided; and at every harsh or violent act of the government his letters express surprise that the men with whom he had acted so long should support such measures. When finally separated from his old aristocratic connections, and convinced by fatal experience that

the House of Commons had sunk into the passive instrument of ministerial power, his opinions became gradually more inclined to parliamentary reform, from utter despair of seeing the revival of those party connections to which he had been accustomed to look for the preservation of public liberty. But if he appealed to the constituent body against their representatives, he only followed the example which the court and his great opponent had given in the memorable dissolution of 1784. Nothing indisposed him so much against the House of Commons as the indifference it manifested on every occasion where liberty was infringed, or injustice committed by the government. "Arguments against the war and our alliances," he observes, in a letter written in 1794, "are favourably heard in the House of Commons, though they do not get us a vote; but sentiments of liberty, and complaints of oppression, are very little attended to, however well founded. In short, liberty is not popular; and of those who are attached to it there are too many who have wild and impracticable schemes of government, to which the miserable state we are in, both with respect to foreign affairs and our constitution, gives more plausibility and credit than they are by their own merit entitled to. The country seems divided (very unequally I admit) between the majority, who are subdued by fears or corrupted by hopes, and the minority, who are waiting sulkily for opportunities for violent remedies. The few who are neither subdued enough to be silent through fear, nor desperate enough to give up regular opposition, in expectation of more violent measures, are weak both in numbers and weight; but, though weak, we are right, and that must be our comfort." But, however changed the sentiments of the country, his own opinions of the value of political liberty were not altered. "I believe," says he, in another letter to the same correspondent, "the love of political liberty is *not* an error; but if it is one, I am sure I shall never be converted from it, and I hope you never will. If it be an illusion, it is one that has brought forth more of the best qualities and exertions of the human mind than all other causes put together; and it serves to give an interest in the affairs of the world, which without it would be insipid." "We live," he observes on another occasion, "in times of violence and of extremes; and all those who are for creating, or even for retaining, checks upon power, are considered as enemies to order. However, one must do one's duty, and one must endeavour to do it without passion." After relating the final junction of his old friends with administration, he adds, "You will easily imagine how much I feel the separation from persons with whom I had been so long in the habit of agreeing; it seemed in some way as if I had the world to begin anew; and, if I could have done it with honour, what I should best have liked would have been to retire from politics altogether; but this could not be done, and therefore there remains nothing but to get together what remains of our party, and begin, like Sisyphus, to roll up the stone again, which, long before it reaches the summit, may probably roll down again."

The last of these extracts shows that, notwithstanding the defection of some of the friends he most loved and esteemed, he was still convinced of the necessity of party connections, in order to maintain the cause of liberty in this country. He argues the question at length with his correspondent, and concludes by saying, "But the decisive argument upon the subject appears to me to be this: Is there any other mode or plan in this country by which a rational man can hope to stem the power and influence of the crown? I am sure that neither experience nor any well reasoned theory has ever shown any other. Is there any other plan which is likely to make so great a number of persons resist the temptations of titles and emoluments; and, if these things are so, ought we to abandon a system from which so much good has been derived, because some men have acted inconsistently; and because, from the circumstances of the moment, we are not likely to act with much effect?" It was with great reluctance, however, and with great violence to his own wishes, that he persevered in this fruitless struggle. "I am quite sick of politics," he says in August 1794, "and attend to them only because I think it a duty to do so, and that it would be unbecoming my character to quit them at such a moment." His desire to retire from public life became stronger in the following year. "I grow every day to think less of public affairs," he says in April 1795; "I wish I could be persuaded that it was right to quit public business, for I should like it to a degree that I cannot express; but I cannot yet think that it is not a duty to persevere. I am so sure that secession is the measure a shabby fellow would take in our circumstances, that I think it can scarcely be right for us; but, as far as wishes, no man ever wished any thing more. I am perfectly happy in the country. I have quite resources enough to employ my mind, and the great resource of literature I am fonder of every day. However, events and circumstances may happen which may make that right, which I am sure would be pleasant, and I think it not unlikely but they may."

The popular spirit manifested against the treason and sedition bills, in winter 1795, revived his public zeal, but was far from giving satisfaction to his mind. "My view of things," he writes in November 1795, "is, I own, very gloomy, and I am convinced that in a very few years this government will become completely absolute, or that confusion will arise of a nature almost as much to be deprecated as despotism itself. Ministers mean to bring on the first of these evils, and I cannot disguise from myself that there are but too many who wish for the second." After his success at the Westminster meeting against the bills, he says, "It is clear we have the popularity, and I suspect we shall have it universally among the lower classes. I need not tell you how I dislike this state of things, but I cannot submit quietly to Mr Hume's *euthanasia*, which is coming on very fast." As he became more persuaded of the existence of a strong spirit of liberty among the lower classes, he became more inclined to the popular doctrines of parliamentary reform. In 1796 he expresses himself in the following manner upon that subject: "Perhaps, instead of saying *now* that the power of the House of Commons ought to be first restored, and its constitution considered afterwards, it would be better to invert the order, and to say parliament should first be reformed, and then restored to its just influence. You will observe that I state this opinion as being mine *now*, in contradistinction to those times when the Whig party was only beaten, but not dispersed, and when I certainly *was* of a different opinion. At present I think we ought to go further towards agreeing with the democratic or popular party than at any former period, for the following reasons: *We*, as a party, I fear can do nothing, and the contest must be between the court and the democrats. These last, without our assistance, will either be too weak to resist the court, and then comes Mr Hume's *euthanasia*, which you and I think the worst of all events; or, if they are strong enough, being wholly unmixed with any aristocratic leven, and full of resentment against us for not joining them, will go probably to greater excesses, and bring on the only state of things which can make a man doubt whether the despotism of monarchy is not the worst of all evils."

The time at length arrived when the state of things to

which he alluded in his letter of April 1795 came to pass. His remaining political friends were persuaded that it was useless to persevere longer in their parliamentary exertions, and that it was even "in some degree hurtful, as tending to deceive the country into an opinion that the House of Commons was still a place in which it was worth while to try the effect of argument and reason." When he found that no good was to be done in parliament, that no beneficial impression was to be made on the country, and that the friends for whom he was ready to sacrifice his time and inclinations wished him to retire from public life, with doubt and hesitation in his mind as to the propriety of the measure, he gave his consent to the secession; resolving no longer to attend his duty in the House of Commons, unless particularly called upon to do so by his own constituents.

Having once retired to St Anne's, he found such enjoyment in the calmness and tranquillity of a country life, that it was with the utmost difficulty he could now and then be brought back to the House of Commons. The happiest years of his life were those which he passed in retirement from 1797 to 1802. He still took a lively interest in public concerns, and applauded and encouraged the exertions of his friends when they returned to parliament, but he could seldom be induced to follow their example. His time passed placidly and agreeably in books, conversation, and the society of his family. He had always been fond of gardening, and his residence in the country gave him a turn for farming. Of the amusements of his early years the love of shooting was the only one in which he continued to indulge, and the exercise it gave him preserved his health. His passion for literature, which had never subsided entirely, revived and became stronger than ever. Poetry and criticism were his favourite pursuits, and history his amusement. He applied with ardour to the study of the Greek tragedians, and as his proficiency increased, he found an agreeable occupation for his mind in the niceties and difficulties of that noble language. Some time after his retreat he conceived the plan of writing a History of the Revolution of 1688. He had many years before expressed himself in the following manner, of the work of our great historian: "I think Mr Hume's History of Charles I. the most mischievous book that ever was written. It is written with infinitely more art than any other part of his work, and is, I think, in that view a masterpiece. I do not think any answer to it or comment on it would do much good, or at least not so much as another history of the times written with his art, or even with the half of it, in the opposite view." But, though his opinion of the utility of a new history of the civil war, as an antidote to Hume, may possibly have first turned his thoughts to a work on English history, the period he selected for his own labours shows that he had no intention to set himself up as a rival to that great historian. His sole object seems to have been, to tell the story of the Revolution, to explain how it was brought about, and to show in what its constitutional value consisted. Had he lived to complete his plan, the criticisms on Hume, in his introduction, would have formed but a small part of his book.

Mr Fox went abroad with Mrs Fox in summer 1802, partly from curiosity to see France after the extraordinary changes that had taken place in that country, and partly to collect documents for his history. As the constant friend of peace, he was received with enthusiasm wherever he went by the French people, and treated with distinguished civility and attention by their government. He had several long conversations with the first consul, in which the latter talked to him with the utmost freedom on a variety of topics; on the concordat then recently made, on the trial by jury, on the licentiousness of the English newspapers, on the difference between Asiatic and European society. On one occasion Napoleon having insinuated that Mr Windham was concerned in the assassination plots against his person, Mr Fox vindicated his old friend with warmth against so odious and unfounded an imputation. Having finished his labours at Paris, during which he collected a large mass of materials for his history, he went to La Grange, the country seat of his friend La Fayette, and after passing some days there most agreeably, returned to England.

On his arrival in London he found great irritation in England against the consular government, and an absurd cry for war raised by the newspapers, and re-echoed by all who expected in any way to profit by that calamity. Ministers were apparently undecided, and, in the hopes of confirming them in a pacific disposition, he resolved for a short time to renew his attendance in parliament. "I shall attend on the address," he says, "because, though, if the ministry is warlike, I have no hope of dissuading them; on the other hand, if they are pacific, I may serve in some degree to encourage them." Besides his general objections to war, where it could be avoided with honour, he thought there was "in this case a moral certainty of failing in our object, and of aggrandizing France still more than we had done." Peace should be preserved, "if it could be done with honour;" and he had no doubt it might, provided our government was so disposed. If Pitt, who had not yet declared himself, should be for peace and Addington, there would be no occasion for the old opposition taking an active part; but if he should join the war party, or "hold a conduct between peace and war," then Addington will want support, "and the support given him will be both useful and honourable." He had been told that he should "be as much abused for pacific language now as he had been ten years before, but being in parliament, he was determined not to blink such a question;" and, on making the trial, found "his speech in favour of peace better received by the house than any he had made since the Russian armament." The country in general, he was persuaded, was inclined to peace; and while there was "hope of contributing to prevent war, he felt himself in a manner bound" not to discontinue his attendance in the House of Commons. When the short session before Christmas closed, he still thought ministers sincerely desirous of maintaining peace. "If I have any fears," he says on the 29th of December 1802, "it is only from a suspicion of a want of courage in ministers to speak out what they really think, and if they should *long* continue to be afraid of speaking bold pacific language, ill humours may arise, and war begin without any wish for it in either government."

It has been invidiously said, that Mr Fox, after his return from Paris, was unwillingly dragged from his retirement by the importunity of his friends, in order to support their views in parliament, and that his health and comfort were sacrificed to their party objects. The fact is directly the reverse. It was he who urged them to attend, not they who solicited him. His return to public life was his own spontaneous act, unsolicited and unexpected by his friends. His object, in the first instance, was to assist in the preservation of peace; and when the message in March 1803 had opened his eyes to the real intentions of the ministry, his indignation at the hollowness and duplicity of their conduct made him persevere in his parliamentary attendance. From the state of parties in the House of Commons he began also to entertain hopes of the revival of a Whig opposition, such as had existed before the fatal schism in 1792; and with his opinions of the necessity of party connections, as the only

means of maintaining public liberty in this country, there was no personal sacrifice he was not willing to make for the attainment of such an end. The revival of his former connection with his old friends was the object nearest to his heart; and in Lord Grenville, though a new associate, he found, as he had formerly done in Lord North, an honourable coadjutor, with whom he could act in perfect confidence, though they had differed warmly on points that were no longer the subjects of public discussion. He was even ready to form a junction with Mr Pitt, till he discovered that Pitt, though willing to join in opposing particular measures of administration, would not break with the court by going into regular opposition. It is a certain fact, that, of all his party, Mr Fox was the person most anxious to form a coalition with Lord Grenville; and that, whatever difficulties occurred to retard that junction, they arose not from him, but from his friends. He considered then, as he had done from the time of the American war, the influence of the crown to be the most dangerous enemy to good government in this country; and the violence expressed for war, after the royal message, contrasted with what he conceived to have been previously the general disposition for peace, he regarded as a strong confirmation of all his apprehensions. "The king's minister," he says in March 1803, "be he who he may, is in peace, at last, all powerful; whether or not, in case of a war, the universal apprehension of mischief from the weakness of those men could do any thing, may be more of a question, but even in that case I think the crown in earnest would beat us all." This influence, he contended, not only governed men's actions, but even swayed their opinions. "I should not be surprised," he says in January 1804, "if in a short time the present minister is reckoned the ablest man in the kingdom; or, if that cannot be compassed, it will be thought and maintained, that a minister without abilities is the best for this country." He was anxious for a junction of parties, not from motives of personal ambition, but in order to counteract this servility. "A stand should be attempted, which, though unsuccessful at present, will keep something alive against other times. To temporise is certain, absolutely certain, confirmation of the evil; no nation ever did, or ever can, recover from slavery by such methods."

The first distinct overture for a formal coalition of what were then called the new and old opposition, was made in January 1804, and came from the friends of Lord Grenville. It was proposed to co-operate in a systematic opposition, for the purpose of overturning Mr Addington's administration, and of substituting in its place one upon the most comprehensive basis possible. To this proposal Mr Fox was willing to have acceded at once; but, owing to some repugnance on the part of his friends, it was settled that the two parties should co-operate and concert together the measures to be brought forward in parliament, in order to give to their debates and divisions all the strength they could, without any formal or compact engagement in case of success. The same proposition had been made to Mr Pitt, who owned that the present ministry was weak and inadequate to the crisis, that their dismission would be a benefit to the country, and that, in case of such an event, an administration should be formed on the broadest possible basis. If his majesty, on such an occasion, were to send for him, he should think it right to endeavour to comprehend in the arrangement all parties, and even those who had been most hostile to him; but though, on many points, he would support the new opposition if it took place, he was determined never to engage with any set of men in systematic opposition. Such was the state of parties at the meeting of parliament in February 1804. As the session advanced Mr Pitt grew more hostile to ministers; and, after the Easter recess, the three parties in opposition acted in concert with so much vigour, that Mr Addington thought it prudent to resign. Mr Pitt, who was sent for to form a new administration, had previously declared that he would endeavour to form one in conjunction with Lord Grenville and Mr Fox; but if he found his majesty impracticable, he should feel himself bound to try one by himself. The result is well known. His majesty was found to be impracticable on the subject of Mr Fox. Lord Grenville, though unfettered by engagements, refused to concur in an administration from which Mr Fox was excluded; and, by his conduct on this occasion, "satisfied those" persons of the old opposition, "who had been most prejudiced" against a junction of the two parties. Mr Pitt, abandoned by all, except his personal friends and adherents, was compelled to coalesce with the wrecks of the administration he had contributed to destroy.

After various ineffectual attempts, during the recess, to strengthen the government, Mr Pitt found himself obliged, before the meeting of parliament, to take back Mr Addington into office. A fresh quarrel ensued; and, at the close of the session, Mr Addington (now Lord Sidmouth) and his friends again resigned. Insinuations were then thrown out of an intention to negotiate with opposition; but, if such overtures had been made, the new engagements contracted on the Continent, independent of other reasons, must have put a stop to the negotiation. Russia, offended at the arrogance of Napoleon, had expressed her desire to form a closer connection with Great Britain. It had been the advice of Mr Fox that advantage should be taken of this disposition to propose reasonable terms of peace to France, under the mediation of Alexander, and, if these were refused, to conclude a defensive alliance with Russia, but on no account to provoke a fresh Continental war, which must ruin Austria if unsuccessful. Unhappily this advice was not taken. Austria was seduced, or rather bribed, into a declaration of hostilities. The war was pre-eminently unfortunate, and all hope for a time extinguished of any balance to the power of France upon the Continent.

The death of Mr Pitt dissolved the administration he had formed. Lord Grenville was sent for by the king, and had no difficulty in persuading his majesty to accept of the advice and services of Mr Fox. When the different parts of the new administration were to be cast, his hope and desire of peace induced Mr Fox to take the office of secretary of state for foreign affairs; and, before his fatal illness, he had begun a negotiation for peace, with every apparent prospect of success. The short time he was in office prevented him from realizing the sanguine expectations which his friends and the public had conceived from his past conduct and principles of government. It ought to be remembered, however, that it was to his firmness Mr Windham was indebted for the success of his limited service bill; a measure that had to encounter every opposition which power and prejudice could raise against it; and that to his exertions, and to those of Lord Grenville, was owing a resolution of both houses of parliament to abolish the slave trade, which Mr Pitt, in the plenitude of his power, had failed to obtain.

Mr Fox had inherited an uncommonly vigorous constitution; but, about two years before his death, he had an illness at Cheltenham, which probably laid the foundation of the malady that occasioned his death. His attendance on Lord Nelson's funeral, in January 1806, brought on a complaint to which he was ever after occasionally liable. The duties of office, and the fatigue of constant attendance on the House of Commons, did not tend to re-

store or confirm his health. About the middle of June he had symptoms of dropsy, both general and local, and soon afterwards his complaint had made such alarming progress as to excite the greatest fears for his life. The universal interest excited in his fate afforded the surest evidence of his great popularity. From the remotest corners of the kingdom letters arrived daily to his family, expressing the deepest concern in his situation, and recommending remedies of all sorts for his disease. His malady, in the mean time, gained ground daily, and his physicians were at length compelled to have recourse to the common surgical operation for dropsy of the belly. The relief obtained, as usual, was but temporary. The operation was repeated, and soon after he fell into a state of languor, from which he never recovered. He expired on the 13th of September 1806, having retained his senses and understanding to the last. It has been said that his death was accelerated by the exhibition of digitalis, administered in the vain hope of effecting a perfect cure of his disease; but the story is utterly false and unfounded, and has been publicly contradicted by his physicians. The cause of his complaint was ascertained to be a schirrous affection of the liver.

"Mr Fox," to use the words of one who knew him well during the last fifteen years of his life, and who has delineated his character with equal truth, force, and discrimination,[1] "united, in a most remarkable degree, the seemingly repugnant characters of the mildest of men and the most vehement of orators. In private life he was gentle, modest, placable, kind, of simple manners, and so averse from dogmatism, as to be not only unostentatious, but even something inactive in conversation. His superiority was never felt but in the instruction which he imparted, or in the attention which his generous preference usually directed to the more obscure members of the company. The simplicity of his manners was far from excluding that perfect urbanity and amenity which flowed still more from the mildness of his nature than from familiar intercourse with the most polished society of Europe. The pleasantry perhaps of no man of wit had so unlaboured an appearance. It seemed rather to escape from his mind than to be produced by it. He had lived on the most intimate terms with all his contemporaries distinguished by wit, politeness, or philosophy, or learning, or the talents of public life. In the course of thirty years he had known almost every man in Europe whose intercourse could strengthen, or enrich, or polish the mind. His own literature was various and elegant. In classical erudition, which by the custom of England is more peculiarly called learning, he was inferior to few professed scholars. Like all men of genius, he delighted to take refuge in poetry, from the vulgarity and irritation of business. His own verses were easy and pleasant, and might have claimed no low place among those which the French call *vers de société*. The poetical character of his mind was displayed by his extraordinary partiality for the poetry of the two most poetical nations, or at least languages, of the west, those of the Greeks and of the Italians. He disliked political conversation, and never willingly took any part in it."[2]

"To speak of him justly as an orator would require a long essay. Everywhere natural, he carried into public something of that simple and negligent exterior which belonged to him in private. When he began to speak, a common observer might have thought him awkward; and even a consummate judge could only have been struck with the exquisite justness of his ideas, and the transparent simplicity of his manners. But no sooner had he spoken for some time than he was changed into another being. He forgot himself and every thing around him. He thought only of his subject. His genius warmed and kindled as he went on. He darted fire into his audience. Torrents of impetuous and irresistible eloquence swept along their feelings and conviction. He certainly possessed above all moderns that union of reason, simplicity, and vehemence, which formed the prince of orators. He was the most Demosthenean speaker since the days of Demosthenes. 'I knew him,' says Mr Burke, in a pamphlet written after their unhappy difference, 'when he was nineteen; since which time he has risen, by slow degrees, to be the most brilliant and accomplished debater the world ever saw.'

"The quiet dignity of a mind roused only by great objects, the absence of petty bustle, the contempt of show, the abhorrence of intrigue, the plainness and downrightness, and the thorough good nature, which distinguished Mr Fox, seem to render him no unfit representative of the old English character, which, if it ever changed, we should be sanguine indeed to expect to see it succeeded by a better. The simplicity of his character inspired confidence, the ardour of his eloquence roused enthusiasm, and the gentleness of his manners invited friendship. 'I admired,' says Mr Gibbon, after describing a day passed with him at Lausanne, 'the powers of a superior man, as they are blended, in his attractive character, with all the softness and simplicity of a child; no human being was ever more free from any taint of malignity, vanity, or falsehood.'

"The measures which he supported or opposed may divide the opinion of posterity, as they have divided those of the present age. But he will most certainly command the unanimous reverence of future generations, by his pure sentiments towards the commonwealth; by his zeal for the civil and religious rights of all men; by his liberal principles, favourable to mild government, to the unfettered exercise of the human faculties, and the progressive civilization of mankind; by his ardent love for a country of which the well-being and greatness were, indeed, inseparable from his own glory; and by his profound reverence for that free constitution which he was universally admitted to understand better than any other man of his age, both in an exactly legal and in a comprehensively philosophical sense." (J. A—N.)

Fox, *George*, the founder of the sect of Quakers, was born at Drayton, Leicestershire, in the year 1624. His father, a zealous Presbyterian, was a weaver. Young Fox, from his earliest years, showed uncommon gravity, and participated in none of the diversions natural to his age; he courted solitude, and when he spoke it was in a melancholy tone. His parents were unable to give him any education beyond reading and writing, but they early inspired him with sentiments of religion and virtue. Fox was at first placed with a wool-merchant, and sent to tend sheep in the woods; a circumstance which seems to have confirmed his

[1] *Character of Mr Fox*, by Sir James Mackintosh. Published in Dr Parr's Collection, entitled *Characters of Mr Fox*, by PHILOPATRIS VARVICENCIS.

[2] This is true of Mr Fox in the latter part of his life only. Till his separation from his old friends in 1793 his mind was too full of political subjects not to take an eager part in political conversation even in private; and, when a young man, instead of being somewhat inactive in conversation, he was very much the reverse. Dr Johnson was mistaken in supposing him habitually silent when in company, and has assigned a reason for his supposed taciturnity quite inconsistent with his real character.

inclination for a solitary and contemplative life. He was then put as an apprentice to a shoemaker at Nottingham; and from the accounts of the times we learn, that as he wrought at his trade, he used to meditate much on the Scriptures, which, with his solitary course of life, improving his natural melancholy, induced him at length to fancy himself inspired; and in consequence he set up as a preacher. He proposed but few articles of faith, insisting chiefly on moral virtue, mutual charity, the love of God, and a deep attention to the inward motions and secret operations of the Spirit; he required a plain, simple worship, and a religion without ceremonies, making it a principal point to wait in profound silence for the directions of the Holy Spirit. Fox met with much rough treatment on account of his zeal, was often imprisoned, and several times in danger of being put to death. But, in spite of all discouragements, his sect, which received the name of *Quakers*, prevailed, and many considerable men were led to join them; amongst whom were Barclay and Penn. Fox died on the 16th of January 1690. He was comparatively an uneducated man, as we have already seen; but he possessed in an eminent degree the talent of persuasion, since, although born in an inferior grade of society, and devoid of any but the simplest instruction, he succeeded in recommending his doctrine to men of a superior rank in society. It was undoubtedly owing to this circumstance that the society of Quakers, or, as they call themselves, Friends, was enabled to outlast so many other sects founded by enthusiasts, which have generally disappeared immediately after the death of their authors; whereas Quakerism acquired every day new force, and the laws which at first persecuted, ended by tolerating and even protecting it. Fox, however, only laid the foundation; it was reserved for Barclay and Penn to raise the superstructure. The writings of Fox have been collected in three volumes folio; the first containing his Journal, which is eminently curious; the second, his Correspondence; and the third, all that he has written on his Doctrine. Some persons have indeed pretended that he is not really the author of these different productions; but his followers, on the other hand, maintain that whatever is most admirable in this collection really proceeded from the pen of their patriarch.

Fox, *John*, the martyrologist, was born at Boston in Lincolnshire, in the year 1517. At the age of sixteen he was entered a student of Brazen-Nose College in Oxford; and in 1543 he took his degree of master of arts, and was chosen fellow of Magdalen College. He discovered an early genius for poetry, and, conformably to the taste of his age, wrote several Latin comedies upon subjects taken from Scripture. Of these, one still remains, entitled *De Christo Triumphante*, printed at London in 1551, and at Bâle in 1556, 8vo, and reprinted in 1672. But having forsaken the muses, he applied himself with great assiduity to the study of theology and church history; and having manifested an inclination, which he took no pains to conceal, for the doctrines of the Reformation, he was, in the year 1545, expelled from his college as a heretic, happy, it is said, to have fared no worse. He had lost his father early in life, and, as his mother had married again, his stepfather availed himself of this occurrence to retain the whole of his patrimony, knowing that Fox would not venture to sue him for restitution. This rascality on the part of his mother's husband reduced him to the greatest distress; but he soon afterwards found an asylum in the house of Sir Thomas Lucy, Warwickshire, who employed him as tutor to his children. When this engagement expired, Fox, who had in the meanwhile married the daughter of a citizen of Coventry, proceeded to London; but finding no immediate means of subsistence, he was again reduced to absolute want. Relief, however, at length came, and in a manner which is described as almost miraculous. As he was one day sitting in St Paul's church, emaciated with hunger, a stranger accosted him familiarly, and, bidding him be of good cheer, put a sum of money into his hand; telling him, at the same time, that new hopes were at hand. And, in fact, he was three days thereafter received into the family of the Duchess of Richmond, as tutor to the Earl of Surrey's children, who, upon their father being sent to the Tower, were committed to her care. In this family he lived at Ryegate in Surrey, during the latter part of the reign of Henry VIII., the entire reign of Edward VI., and part of that of Queen Mary; but he could never discover the generous person who had at once relieved his distress and predicted his good fortune. At length, however, being persecuted by his implacable enemy Bishop Gardiner, he was obliged to seek refuge abroad; and he selected as the place of his retreat Basil in Switzerland, where he subsisted by correcting for the press. But on the death of Queen Mary he returned to England, where he was graciously received by his former pupil the Duke of Norfolk, who retained him in his family as long as he lived, and bequeathed him a pension at his death, which took place in 1563. Mr Secretary Cecil also bestowed on him a rectory near Salisbury; and, in point of fact, he might have obtained considerable church preferment, had it not been for his unwillingness to subscribe to the canons. He died in the year 1587, in the seventieth year of his age, and was buried in the chancel of St Giles's, Cripplegate. Fox was a man of great industry, and considerable learning; a zealous, but not a violent reformer; a nonconformist, but not an enemy to the Church of England. The most celebrated of his works is that which is entitled *Acts and Monuments of the Church*, and commonly called *Martyrology*, containing a history of the troubles in the Church of Rome, since the tenth century, particularly in England and Scotland. It was published at London, 1563, in folio, but afterwards augmented and printed for the fourth time in 1583, two vols. folio, and in 1632, three vols. folio. He relates in detail the history of the martyrs of the Protestant religion, but embellishes his narrative with so many marvellous circumstances, that his enemies, it must be confessed, had some reason in applying to it the name of Legend. The Catholics, in particular, reproached him with passion and with grossness; and, what was far more serious, accused him of having often altered the truth in order to swell the number of martyrs to his creed. Nor can it be denied that in the first edition, he had enrolled amongst the number of those who had sealed their testimony with their blood persons still living, and who remonstrated against the honour intended for them. But notwithstanding all these and many other objections, some of which are undoubtedly well founded, the *Martyrology* met with prodigious success in England, where, amidst all the changes which have taken place in taste and opinion, it still maintains its ground. The other writings of Fox, which were very numerous, consist of works on theology, and particularly controversy; and some of his letters which have been preserved reflect honour on his character as a man of sense and humanity.

FOX-GLOVE (*Digitalis purpurea*), an herbaceous plant, inhabiting the temperate and southern parts of Europe. See BOTANY, vol. v., p. 202. Nat. Ord. *Scrophulariaceæ*. The flowers of this beautiful plant are usually purple; but sometimes white. When fresh, it possesses a bitter, nauseous taste, and is violently emetic and cathartic. When prepared and administered medicinally, it has the remarkable property of diminishing the strength and frequency of the pulse, and is at the same time diuretic; hence it is much esteemed as a remedy in diseases of the heart and dropsy.

FOYLE, a river and lough in Ireland. See DONEGAL.

FRACASTORIO, HIERONYMOUS, one of the most learned men of his time, was born at Verona in the year 1483. Two singular circumstances are related of him in

his infancy; one that his lips adhered so closely when he came into the world, that a surgeon was obliged to divide them with his incision knife; and the other, that his mother was killed with lightning, whilst he, though in her arms at the moment, escaped unhurt. Fracastorio was a man of such admirable parts, and made so great progress in everything he undertook, that in time he became eminently skilled not only in the belles-lettres, but in most arts and sciences. He was a poet, a philosopher, a physician, an astronomer, and a mathematician; and he was also a man of consequence in his time, as appears from the fact of Paul III. having made use of his authority to remove the council of Trent to Bologna, under the pretext of a contagious distemper, which, as Fracastorio declared, made it no longer safe to continue at Trent. He was intimately acquainted with Cardinal Bembo, Julius Scaliger, and most of the great men of his time. Fracastorio died of apolexy at Casi, near Verona, on the 8th of August 1553; and in 1559 the town of Verona erected a statue in honour of him. Fracastorio was the author of many works, both as a poet and a physician; but no man was more disinterested in both capacities, for as a physician he practised without fees, and as a poet he was indifferent to fame. It is owing to this that we have so little of his poetry; and that his odes and epigrams, which were read in manuscript with admiration, have now been lost. His medical productions are as follow:—

Syphilidis, sive Morbi Gallici libri tres, Verona, 1530, in 4to, afterwards frequently reprinted. *De Vini Temperatura*, Venice, 1534, in 4to. *Homocentricorum, sive de Stellis liber unus*, and *De Causis Criticorum Dierum libellus*, Venice, 1535, in 4to. *De Sympathia et Antipathia Rerum liber unus; De Contagionibus et Contagiosis Morbis, et eorum curatione, libri tres*, Venice, 1546, in 4to. All the poetical productions of Fracastorio were collected and printed at Padua, 1728, 8vo. His complete works appeared for the first time under the title of *Hieronymi Fracastorii Veronensis Opera Omnia, in unum proxime post illius mortem collecta; accesserunt Andreæ Naugerii patricii Veneti Orationes duæ, Carminaque nonnulla*. Venetiis apud Juntas, 1555, in 4to. Besides the works already mentioned, there are included in this collection the three following, which appeared for the first time, viz.:—*Naugerius, sive de Poetica dialogus; Turrius, sive de Intellectione dialogus, libri ii. Alcon, sive de cura Canum Venaticorum. Fracastorius, sive de Anima dialogus.*

FRACTION, in *Arithmetic* and *Algebra*, a broken part or division of an unit or integer; or a number which stands to a unit in the relation of a part to its whole. Fractions are usually divided into decimal, sexagesimal, and vulgar. See ALGEBRA, and ARITHMETIC.

FRACTURE. See SURGERY, and MINERALOGY.

FRAISE. See FORTIFICATION.

FRAME, among *printers*, a stand to support the cases in which the types are distributed. Among *founders*, a kind of ledge inclosing a board filled with wetted sand, and which serves as a mould for castings. It also denotes a sort of loom, on which linens, silks, or stuffs are stretched for embroidering or quilting.

FRAMLINGHAM, a market-town of England, county of Suffolk, on an eminence near one of the sources of the Alde, 14 miles N.E. of Ipswich. The church is a fine old edifice, constructed of black flintstone, with a carved roof and several monuments of the Norfolk family, and surmounted by a tower 96 feet high. The castle of Framlingham was an important fortress in the middle ages, and hither Queen Mary retreated on the death of Edward VI. The remains consist of the walls, 44 feet high and 8 feet thick, 13 towers 58 feet high, a gateway, and some outworks. Market-day Saturday. Pop. of parish (1851) 2450.

FRANC, a French silver coin of the value of nearly tenpence sterling. The ancient franc, or frank, was a gold piece in value somewhat more than the gold crown; and the old silver franc was in value a third of the gold one.

FRANCAVILLA, a town of Naples, province of Otranto, 14 miles W.S.W. of Brindisi. The town is large and regularly built, the streets are wide and straight, and the houses showy, though in a heavy style of architecture. A considerable part of the town was thrown down by an earthquake in 1734, and the houses erected since are only one story high. The main street is handsome, and avenues to the gates are well planted, and afford an agreeable shade. It has a cathedral, college, several hospitals and convents; and manufactures of woollen and cotton stuffs, earthenware, and snuff. Pop. 12,000. There are several other towns of this name in Naples.
